The Jordanburn Hospital is an entirely new venture under the new Charter, and is a voluntary institution for patients suffering from all that is comprised by the term "nerves." Its out-patient clinic is held every morning and provides facilities for every modern psychological investigation and treatment, including a child guidance clinic, social service department, mental deficiency section, and neurological department. The scheme will be completed later with the erection of laboratories in connexion with the magnificent lecture theatre. In the six nursing homes associated with Morningside and situated in the suburbs of Edinburgh, there were 93 patients at the end of 1928. These are specially equipped for nerve patients, and each has its own peculiar features, so that a change from one to another can often be made with benefit. The number of admissions, from all parts of Great Britain, is steadily increasing. At the main institution there were at the end of the year 155 voluntary and 705 certified patients. During 1928 applications for admission were received from 114 voluntary patients, and 98 certified. The medical superintendent discusses again the lamentably small number of poor voluntary patients received into the mental hospitals of the country. The usual details and tables are not supplied with this report.

The 128th report of the *Aberdeen Royal Mental Hospital* for 1928 records that there were 810 patients at the end of the year; 21·8 per cent. of the private admissions were on a voluntary basis, but only two rate-aided voluntary boarders were admitted. Seventy-six of 181 admissions were suffering from some bodily illness, and 12 from epilepsy. One general paralytic was discharged as cured without having had any special treatment, and five were able to return to work after malarial inoculation. The total recovery-rate was 25·96 per cent., and the death-rate 8·3 per cent. Six cases of paratyphoid occurred on the female side, and there were two cases of scarlet fever. T.A.B. vaccine and scarlatinal antistreptococcus serum were used respectively to immunise the contacts. The dentist examined over two hundred patients, of whom 170 required treatment. Eighty-two patients received ultra-violet radiation, most of them on account of physical conditions; anæmia was benefited and sleep, appetite, and weight improved. No lasting mental improvement was observed. Nearly a hundred cases were X rayed during the year. Rather more than a hundred patients were employed in the occupational therapy department on very varied crafts, and many discharged patients continue the work in their own homes. Research work is being carried on in the laboratory in addition to a large number of routine investigations. A cinematograph with non-inflammable films has been bought for the branch institution at Daviot, and has given much pleasure; one unfortunate patient had never seen a moving picture before, and was greatly alarmed at the first entertainment!

The *Glasgow Royal Asylum* publishes for 1928 its 115th annual report, illustrated as usual by a number of photographs. There were 536 patients resident at the end of the year, and 68 of the 135 patients admitted were voluntary boarders. Forty-five patients were discharged recovered and 34 greatly improved. The death-rate was 4·7 per cent. In redecorating the building attention has been paid to the influence of colour schemes on mental health. The kitchen has been centralised and reorganised, and much labour saved thereby. The seaside home at Skelmorlie and the nursing home at Dowanhill continue to render valuable service. The visiting dentist reports that he saw 204 patients, and practically none of them objected to treatment. The occupational therapy officer describes a very successful year in her department. Many patients on parole spend their day there, and some of them take away material to work at in their rooms. Every now and then a handicraft is dropped altogether so that it can be taken up later with a feeling of novelty. Nurses and attendants work among the patients and help the atmosphere of industry and life in the department. The amount realised from sales has more than defrayed the cost of materials. Four nurses and five attendants passed the senior examination of the General Nursing Council. The medical superintendent emphasises again the need for a psychiatric clinic, and discusses the popular attitude to mental illness.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED JULY 20TH, 1929.

Notifications.—The following cases of infectious disease were notified during the week: Small-pox, 144 (last week 115); scarlet fever, 1864; diphtheria, 949; enteric fever, 56; pneumonia, 935; puerperal fever, 46; puerperal pyrexia, 87; cerebro-spinal fever, 12; acute poliomyelitis, 9; acute polio-encephalitis, 1; encephalitis lethargica, 28; continued fever, 2; dysentery, 11; ophthalmia neonatorum, 129. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the Metropolitan Asylums Board on July 23rd–24th was as follows: Small-pox, 173 under treatment, 3 under observation (last week, 198 and 11 respectively); scarlet fever, 1405; diphtheria, 1046; enteric fever, 11; measles, 208; whooping-cough, 373; puerperal fever, 31 (plus 11 babies); encephalitis lethargica, 124; "other diseases" 24. At St. Margaret's Hospital there were 10 babies (plus 10 mothers) with ophthalmia neonatorum.

Deaths.—In the aggregate of great towns, including London, there was no death from small-pox, 3 (1) from enteric fever, 38 (8) from measles, 1 (0) from scarlet fever, 25 (8) from whooping-cough, 10 (4) from diphtheria, 65 (13) from diarrhœa and enteritis under two years, and 27 (2) from influenza. The figures in parentheses are those for London itself.

Birmingham and Liverpool each reported 6 deaths from measles, Leeds 4, and Bradford 3. Whooping-cough claimed 3 victims in Birmingham. Diarrhœal deaths were at their maximum in Liverpool 8, Birmingham 7, and Wolverhampton 3.

The number of stillbirths reported during the week was 291 (corresponding to a rate of 42 per 1000 births), including 50 in London.

Death from Small-pox.

THE fatal case reported last week from Stepney was that of a female infant, aged 3 days, whose certificate was filled up thus: 1. (*a*) Small-pox. (*b*) Unvaccinated, born with a rash, mother suffering from small-pox: 2. Prematurity. Dr. D. L. Thomas, medical officer of health, tells us that the infant's mother, having had a rash for about a week, was taken with labour pains on June 29th and removed to the Mile End Hospital where she gave birth a couple of hours afterwards. The baby, it seems, showed no rash for the first 12 hours, but when seen on July 1st had a profuse eruption. The case is an interesting one, inasmuch as the baby contracted the disease in utero.

ROUSSEAU'S RETREAT AS TUBERCULOSIS HOSPITAL. The Stoke-on-Trent City Council has obtained an option for the purchase of Wootton Hall as a tuberculosis hospital. Wootton Hall, which is romantically situated on the Staffordshire bank of the Dove, was from March, 1766, to May, 1767, the home of J. J. Rousseau, who there wrote the early part of his "Confessions." The village of Ellastone in which it stands is the Hayslope of "Adam Bede," and Wootton Hall is the Donnithorne Chase of that book.

VILLAGE SETTLEMENTS AND CENTRES.—Last week the Duke and Duchess of York paid their second visit within five years to the Papworth (Cambridgeshire) Village Settlement for Consumptives. The Settlement, which came into existence 12 years ago, with two shelters in a garden, is now a community of 700 persons who are able to support themselves by various handicrafts. The ex-patients live in cottages amid perfect sanitary conditions, and although 100 children have been born of parents one of whom is tuberculous, no trace of the disease has been found in any of them. The Papworth Industries have increased their turnover from a few hundred pounds in 1918 to £54,000 in 1928, and men and women who would normally be unemployable have received £112,000 in wages.—At the annual meeting last week of the Village Centres, Curative Treatment and Training Council, Incorporated, Field-Marshal Lord Plumer, who presided, reported that the income had fallen off. No appeals for money were made during the last two years, for fear of conflicting with those for the Haig Memorial Homes, nor had there been any appeals on Armistice Day, yet only £16,500 had been received from the British Legion. The factory is working efficiently, but it was stated that an income from donations and subscription of at least £7000 per annum is required; last year there was a loss of £400.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Adjournment for Summer Recess.

Parliament adjourned on Friday, July 26th, for the summer recess. Both Houses will reassemble on Tuesday, Oct. 29th. The Royal Assent was given by Commission to the following Acts:—Colonial Development Act and the Housing (Revision of Contributions) Act.

Poor-law Administration.

In the House of Commons on Tuesday, July 23rd, Mr. Neville Chamberlain moved that a humble address be presented to His Majesty praying that certain Orders made by the Ministry of Health, dated June 27th, 1929, in reference to the Bedwelty, Chester-le-Street, and West Ham Unions, in which appointed guardians are functioning under the Guardians (Default) Act, should be annulled. He said that the Orders purported to extend the period of office of the present appointed guardians until August 2nd, but he understood that the Minister of Health intended to dismiss them on that date and by a new Order to substitute other appointed guardians who would function until April 1st next. Since the appointed guardians had been at work all further borrowing by the unions concerned had ceased and the financial position had improved. In addition, the West Ham appointed guardians had increased the efficiency of the medical and nursing service at the hospital by appointing four consultants—a gynæcologist, an orthopædic surgeon, an ophthalmic surgeon, and a neurologist. They had appointed a dentist and an anæsthetist, they had added one medical officer to the staff, and had substituted 14 staff nurses for a corresponding number of probationers. In the children's homes they had provided a new and more varied diet at an additional cost, and had changed the clothing of the children, which was heavy and unsuitable, for lighter and healthier garments. They had encouraged games and outdoor exercises for the children, and had also encouraged them to join the local groups of boy scouts and girl guides. In place of part-time district medical officers full-time medical officers had been appointed, and the number of district nurses had been increased. The report on their work showed that not only was the administration of the old guardians extravagant but also grossly inefficient, and the hard-hearted, callous bureaucrats, as they were described by hon. Members who did not approve of anything that the late Government did, had really effected a revolution in the efficiency of the service as well as in the financial position. Now these people were to be swept away as if they had done something to be ashamed of instead of pulling West Ham out of chaos into order, and in their place were to be put people who would be nominated by the local authority. In view of statements which had been made by members of the Labour party in the West Ham area, and the fact that under the Local Government Act something like £250,000 of public money was to be handed over from the Exchequer to be distributed in that area towards the local rates, he thought there was danger in the course which the Minister of Health proposed to take. He hoped that Mr. Greenwood would indicate that he stood up for the best principles of poor-law administration, and that he was not prepared to commit himself to practices such as those which led to the passing of the Guardians (Default) Act.

Mr. Greenwood, Minister of Health, said that he wished to see boards of guardians doing their honest duty in an enlightened and humane way, without extravagance and without placing an enormous burden on the other people who were paying the rates and who in many cases he realised were very little better off. He had no reason to believe that they would not get wise and fair administration from the newly appointed boards of guardians when they took office. All or most of them were persons of considerable experience; they were being given a trial trip and they would be able ultimately to introduce the county councils and the county borough councils in those areas to the real problems which they had to face. He could think of no other way of dealing with the question than the one he had adopted. He could not have squared it with his conscience to leave the three appointed guardians there for another eight months.

After further debate,

The Constitutional Issue.

Miss Susan Lawrence, Parliamentary Secretary to the Ministry of Health, said that there was a serious constitutional issue involved. The late Minister of Health took power to himself to appoint three persons or any number that he liked as guardians. He fixed their salaries and he could appoint them for a given time. For the acts of these persons the Minister was not accountable to Parliament. It might be said that there were precedents. Mr. Chamberlain had tried to cover himself with the name of Mr. Gladstone by pointing out that the great Act of 1870 allowed of the supersession of a school board and the appointment by the Minister of substitutes. But in that case the Minister had to certify the expenses of the displaced school board, which brought them under full Parliamentary control. So in later Acts, such as the Public Health Act of 1875, the power was taken to place the Minister—that was Parliament—in the room of local authorities, but there was not a single other Act which allowed the Minister to have at his disposal persons for whom he could not answer to Parliament. It would be a real danger if such a class of persons were allowed to grow up, particularly in local government. They saw abroad the degradation of local government by these quasi-executive ambiguous officers like burgomeisters and préfets, persons clothed with the authority of the executive and charged from headquarters with keeping the local authorities in their places. Whatever might have been wrong the remedy put forward by the Guardians (Default) Act was the wrong remedy.

Mr. Chamberlain: Will the hon. lady explain how she has met that constitutional point in the change which is proposed to be made by these Orders?

Miss Lawrence: Unless some Order of this kind was made there could be no board of guardians. We could not have an election without legislation and we could not allow all poor-law relief to lapse. We therefore made what I call a gesture and handed over in effect the nomination of these persons to the elected authorities who will deal with them now.

The motion for an address was negatived by 284 votes to 154.

The Housing Subsidy.

The Housing (Revision of Contributions) Bill passed through Committee and was read the third time and passed.

The National Radium Trust.

On Wednesday, July 24th, the House went into Committee on a supplementary vote of £100,000 as a grant-in-aid of the National Radium Trust. Mr. Dunnico, Deputy Chairman of Committees, was in the Chair.

Mr. Greenwood, Minister of Health, said that he did not imagine that there would be much controversy about this vote. It was an inheritance which had come to him from the late Government, and its purpose was to provide for a grant-in-aid of the National Radium Trust, subject to a maximum of £100,000, based on £1 for every £1 of voluntary subscriptions; for augmenting the supply of radium for use in the treatment of the sick, and for the advance of knowledge of the best method of rendering radiological treatment. The money would be expended by the trust under the terms of a Royal Charter incorporating that body. The recommendations of the Radium Subcommittee of the Civil Research Committee, published in a report early this year, were accepted in principle by the late Government subject to further consideration on matters of detail. Since that time a consultation had taken place with the leaders of the various branches of the medical profession, and certain minor changes had been made in the proposals of the subcommittee. It was finally thought to be expedient to appoint the Radium Trust and the Radium Commission through the instrumentality of a Royal Charter, and a Royal Charter had now been received from the King empowering the establishment of the Trust and the Commission. The Trust would hold the money and would be responsible for the actual ownership of the radium. The Commission would be the body responsible for its custody, care, and utilisation. The Radium Trust would consist of the Lord President of the Council, who would be chairman, the Minister of Health, the Secretary of State for Scotland, the President of the Royal Society, the President of the Royal College of Physicians of London, the President of the Royal College of Surgeons of England; the chairman of the Central Liaison Committee for Voluntary Hospitals in Scotland, the President of the Royal Society of Medicine, and the President of the British Medical Association. The Trust were also required to coöpt two medical members of the Commission and might coöpt not more than three other persons. That matter was now under consideration, and it would be the function of that body to accept and to hold the funds which had been subscribed and to purchase the radium. The Radium Commission, which would be responsible for the custody, distribution, and use of the radium, would consist of a chairman to be appointed by the Trust; four members nominated by the Minister of Health, the Secretary of State for Scotland, the Medical Research Council, and the Department of Scientific and Industrial Research; and six members having special knowledge and experience of the application of radium in the treatment of the sick. These six persons were to be appointed by the trustees from a panel of 12.

ROYAL MEDICO-PSYCHOLOGICAL ASSOCIATION.

ANNUAL MEETING.

THE annual meeting of this Association took place in London on July 10th, 11th, and 12th, under the presidency of Dr. NATHAN RAW, C.M.G., who delivered a presidential address on

Fear.

He began by saying that fear was of immense importance to the community and of particular concern to a large number of individuals. A high authority had stated that fear was the driving force of life, without which there would be quiescence and no bodily reactions. Certainly if we had no fear our instinct of self-preservation would be useless. But an aspect which had an enormous bearing on life was a needless and morbid apprehension. The late Dr. Mercier entitled his book "Disorders of Conduct," averring that of mind he knew nothing. Dr. Raw quoted in full Mosso's classical description of his own feelings when called upon to make a speech, and added his own observations on men afflicted with stage fright when required to address their fellows. A former master of his own, who was a professor of rhetoric, at the beginning of a nervous affection could only speak sitting, owing to excessive trembling of the legs, and at last he had to renounce the triumphs of his great eloquence as he was afflicted with a temporary paralysis. The President thought the only way to find a solution of this distressing state was to analyse, without prejudice, all that was known about cerebral activity, and to see what physiologists had discovered in studying the emotions and the physical phenomena of thought.

He acknowledged that it was normal to fear; it was one of the emotional manifestations of a primal instinct and ordinarily expressed itself in efforts at flight or concealment. The Langue-James theory contended that an emotion was the sensation of the visceral changes accompanying it. There was no need of proof that visceral changes accompanied fear, pallor of skin, trembling of limbs, dilatation of pupils, protrusion of the eyes, which were said to be due to excitation of the adrenals. Reflex action played an important part in the exhibition of fear. The Langue-James theory was rejected by many great psychologists. The real solution was that fear was indicative of a defensive mechanism, that this was excited by the perception and realisation of danger, which set in motion a physical mechanism to defend life. Sherrington, by his brilliant work, showed that in animals the basal ganglia were the seat of the primary instincts and emotions. Hughlings Jackson taught that the emotion of fear arose in the cerebral cortex. Cowardice was uncontrolled fear; it was abnormal and antisocial to be a coward. The really brave man did not run away, but not because he had no fear; he overcame it and faced the danger. There was, however, a limit to human endurance, and the diabolical methods used in the late war had played havoc with the nervous systems of thousands of brave men, so that they would never recover.

Fear associated with disease was well known. Delirium tremens was not now nearly as frequent as it was 20 years ago. Edgar Allan Poe, who died of it at 37, had left a ruthless analysis of the experience. Many people lived in constant dread of such diseases as cancer, tuberculosis, blindness, or insanity.

National fear was of immense importance; whole communities might be seized with a subdued fear of attack from more powerful neighbours. The question was often asked: Is religion based on fear? It has been said that fear formed the stock-in-trade of many irrational forms of ecclesiastical propaganda. When religion, which should appeal to the highest instincts in man, debased itself to the point of appealing to the lowest and meanest instincts, it undermined the very foundations of character, poisoning the fountain of life at its source. Any religion which appealed primarily to fear was doomed to decay with the dawn of more universal intelligence. The fear of death had long been recognised as an instinct, and Rousseau said that he who pretended to face death without fear was a liar. This fear was a natural impulse, and was not merely an accident. Schopenhauer, however, said that from the point of view of intelligence there was no ground for fearing death; only those with blind faith could subdue this fear of death. The finest examples in history of the calm resignation to the inevitable were furnished by the aristocrats of France when perishing by the guillotine in the French Revolution.

The description of the human emotions given by Charles Darwin 57 years ago had never been excelled. Worry was a comparatively recent product, though fear dated from the dawn of human intelligence. No children should be brought up to fear their parents or anything else. And too many teachers seemed to think that their secondary, if not their chief, function was the creation in their pupils of inferiority complexes; certainly worry over examinations was a prolific cause of academic failure. We could never hope to conquer fear, but we should learn to control it.

Dr. REGINALD WORTH proposed a cordial vote of thanks to the President for his address, and Dr. BEDFORD PIERCE seconded.

On July 11th Dr. W. M. FORD-ROBERTSON (Northampton) read a paper entitled

Some Cases of Mental Disorder: A Patho-Clinical Study.

In recent years, he said, research into mental disorders had tended to become, more and more, the study of the pathology of the living, and to this the advances of biochemistry had largely contributed. He did not think the study of focal infection by bacteriological methods would lead very far. More effort should be made to correlate its local and remote effects in disordered metabolism, disturbed endocrines in relation to the patient's economy as a whole. It seemed that in mental disorders one had to deal with bacteria of a special type, which probably could only adapt themselves as chronic infective agents to a certain group of the community, i.e., those who had a neurotoxic susceptibility. This needed that one should search for new methods of bacteriological technique, study the results, and attempt to correlate cause and effect. Knowledge of the somatic disorders underlying insanity was, as yet, so limited that attempts to continue on these lines would lead only hesitatingly along the progressive path. Efforts should be concentrated more on the individual as a problem in pathology. There had been up to the present a lamentable lack of proper collaboration between biochemist and bacteriologist.

Dr. Ford-Robertson's main thesis consisted of a detailed account of the findings in 120 cases of mental disorder which had been thoroughly overhauled, and four of these were given with minuteness. They served, he said, to emphasise how complex, indeed elusive, were the problems of the physical disorders underlying insanity. His observations led him to believe that the person of psychotic tendencies failed to reveal clearly the underlying pathology of the internal environment by ordinary signs and symptoms. Surgical removal of foci of infection alone could not bring about recovery. Yet focal infection was of the greatest importance in mental disease. He had satisfied himself that the insane harboured anaerobic bacteria of the diphtheroid and lepto-streptothrix group which often infected the major part of the alimentary canal.

Dr. W. F. MENZIES (Cheddleton) discussed the contribution at some length, and expressed regret that the association had not provided in its rules for the admission of the pure biochemist, as he would be a great acquisition for this kind of research.

Dr. J. R. LORD (Epsom) also spoke, pointing out that it was not so much a matter of the presence of septic foci in these cases, but that the toxins were absorbed. In the latter event a biochemical problem arose, which, if not adjusted, led to dysfunction of some part of the nervous system. Neuro-toxins seemed to have a degree of selectivity of action, different toxins selecting different functional zones.

Other Subjects Discussed.

Dr. GORDON PETERS (Epsom) read a paper on Charcot's Joints in Tabo-paresis. He related three cases of general paralysis of the insane who were also afflicted with Charcot's disease of the spine. One remarkable case was that of a woman of 29, the subject of congenital tabes who had suffered from Charcot's spine from an early age.

The morning of July 12th was taken up with a consideration of the Report of the Mental Deficiency Committee (1929), the discussion being introduced by Dr. A. F. TREDGOLD.

In the afternoon Dr. LORD spoke on a Modern Approach to the Problem of the Admission of Mental Patients to In-patient Treatment. The points he dealt with specifically were: (1) the non-intervention at any point of a judicial authority; (2) the administrative recognition of the non-volitional case; (3) the power of local authorities to deal with (and retain as necessary) occurring mental disorder on lines as far as possible parallel with those practised in regard to infectious and other physical diseases; (4) notification of all non-volitional and involuntary cases to the local authority, and the latter also to a central authority; (5) certification to be abolished and replaced by a system of confirmation or continuation of the initial action taken by the local authority, or by a panel specially nominated by the local authority; (6) all institutions receiving voluntary cases who are retained voluntarily and non-volitional cases to be registered and subject to visitation by the local authority; (7) active prophylaxis by the psychiatrisation of public assistance work.

A discussion followed.

On Wednesday the Association dined together, with the President in the chair, and the guests included Lord Riddell, the Mayor of Westminster, Dr. Pameijer, Sir Arthur Robinson, and several foreign delegates. On Thursday afternoon a reception and garden party took place at Springfield Mental Hospital.

Obituary.

KENNETH ARTHUR LEES, O.B.E., M.B., B.CHIR. CAMB., F.R.C.S. ENG.,

ASSISTANT SURGEON FOR DISEASES OF THE THROAT, NOSE AND EAR, ST. MARY'S HOSPITAL, PADDINGTON.

Kenneth Lees, who died following an operation for cerebral tumour on July 23rd at the age of 48, was the son of the famous physician David Lees, and early decided to follow his father in the study of medicine. He passed from school to King's College, Cambridge, gaining a first-class in the Natural Science Tripos in 1903. In 1905 he elected to join St. Mary's Hospital, where his father, originally a Guy's man, was giving clinical teaching to crowds of appreciative students. Though his untiring energy and keen enthusiasm, when he was working under his father's inspiration, were apparent, Kenneth Lees showed a great inclination towards surgery. He qualified M.R.C.S., L.R.C.P. in 1907, took his Cambridge degree in 1909, and became F.R.C.S. Eng. in 1912. He held a succession of resident posts at St. Mary's Hospital, and in 1914 was promoted to be surgical registrar. During the war years this post was a strenuous one. It involved full afternoons in the theatres and emergency operations, as well as much of the teaching in wards and out-patient department normally undertaken by members of the honorary staff. All those who worked with Mr. Lees during those trying times, when the staff was seriously depleted as the result of the war, testify *to his unfailing promptness in answering every call,* night and day, and to his equanimity and urbanity. The students who passed through the hospital during this time were indebted to him for coaching at unconventional hours, and many owe their examination success to his conscientious efforts and good-humoured ragging. His services to the hospital were recognised by the award of the O.B.E.

Though Mr. Lees always retained a great liking for general surgery, circumstances led him to specialise in diseases of the nose, throat, and ear; he was appointed to the staff of St. Mary's in 1919, and later to other hospitals, including the Queen's Hospital for Children, Hackney. His interest in this branch of work increased every year, and his wide surgical experience gave him from the outset a mature outlook on all aspects of a case which many specialists only acquire late in life.

Outside his work Mr. Lees had many interests. He enjoyed golf, and his car meant more to him than just a means of easy transport. He was a keen Mason and he was Worshipful Master of his hospital Lodge at the time his fatal illness manifested itself. Kenneth Lees was retiring in disposition, but in congenial company he showed a whimsical humour and keen appreciation of wit in others. He married, a few years ago, a niece of the late Dr. William Hill.

THOMAS EAGLESON GORDON, M.B., B.CH.,

PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS IN IRELAND

PROFESSOR OF SURGERY, TRINITY COLLEGE, DUBLIN.

THE death occurred on July 27th, at his residence in Dublin, of Prof. T. E. Gordon, President of the Royal College of Surgeons in Ireland, in the sixty-third year of his age. He had been in bad health for several months past, and had recently resigned his post as Surgeon to the Adelaide Hospital, Dublin.

PROF. T. E. GORDON.

Photo by Lafayette, Dublin

Thomas Eagleson Gordon, a North Irishman by birth, was educated at Trinity College, Dublin, doing his professional courses at the Adelaide Hospital; he graduated in 1890, and in 1895 took the Fellowship of the Royal College of Surgeons in Ireland. After holding a resident appointment at the Adelaide Hospital, he was appointed Assistant Surgeon; he had already been elected Visiting Surgeon to the City of Dublin Hospital, but resigned this post to return to the Adelaide Hospital. His professional career was bound up with this institution, for he remained in active work there for 35 years, and was senior surgeon from 1915, until ill-health forced his retirement a few months ago. In 1919 he was appointed to the chair of surgery in Trinity College in succession to the late Mr. E. H. Taylor, and during the war was attached to the 83rd (Dublin) Hospital, B.E.F., with the rank of lieutenant-colonel.

Prof. Gordon was an attractive and accomplished teacher, both in hospital and in his professorial work, while he was particularly interested in his duties as curator of the pathological museum in Trinity College, and did much to make the splendid collection of Robert Smith and Edward Bennett more readily available for teaching purposes. He was a man of wide culture, well read in history and archæology. He was elected President of the Royal College of Surgeons in Ireland last year, and in June of this year was elected for a second year. His death is greatly regretted by his professional brethren.

JOHN BROWN, M.D. MANCH., D.P.H.

FOR many years medical officer of health for Bacup, Dr. John Brown died on July 29th at Blackpool, where he had been living in retirement. He was born at Callington, in Cornwall, in 1849, and attended school there before going up to University College, London. He started the study of medicine at Charing Cross Hospital, and gained a number of scholarships and prizes in that school. On qualifying as L.R.C.P. and L.S.A. Lond. in 1877 he was appointed house surgeon to the Western Ophthalmic Hospital, and later in the same year medical officer of health for Bacup. As a post-graduate student of Owen's College he became M.B. in the Victoria University of Manchester in 1888, when he also took the diploma in sanitary science. Dr. Brown was a prolific writer, and belonged to numerous medical societies in Manchester and elsewhere. His experience in the public health service was considerable, for he undertook many branches of the work of his district. During the 15 years of retirement, which he spent in Blackpool, he devoted a good deal of attention to the subject of cancer. He leaves a widow and five sons, two of whom, Dr. J. P. Brown of Bacup, and Dr. G. B. Brown of Manchester, are members of the medical profession.

Correspondence.

"Audi alteram partem."

AURAL DISEASE AND BATHING.

To the Editor of THE LANCET.

SIR,—Though it has long been known that frequenters of swimming baths, especially deep divers, run some risk of infection of their noses, throats, and ears, the marine bathing pool, to my knowledge, has not yet been impugned. Last summer on my holiday I had the opportunity of daily observation of one such pool, which enabled me to draw certain deductions. This swimming pool had been made by enclosing a portion of the foreshore with a sea wall, the summit of which was completely submerged at every high tide. This arrangement ensured a certain amount of change in the supernatant layer or layers of water, but the bed of the pool necessarily remained undisturbed, and consequently pollutions must have slowly deposited by sedimentation, and would consist of the usual dead organic material found in swimming baths, such as human hair, material from the noses, throats, mouths, intestines, and skins of former bathers, also the remains of dead fish, crustacea, &c. To cleanse such a pool seemed to me to be an impossibility, as the bottom of the deeper portion of the pool was covered with rocks and boulders which had been enclosed when the encompassing sea wall was erected. There was one sea gate or sluice which could be opened, but this only extended to half the depth of the wall, and was consequently useless from the point of view of draining the floor of the pool.

Bathers would be wise to content themselves with the open seashore, and avoid such types of pools, though the keen swimmer would miss thereby the many gadgets, such as diving boards and slides, which render the pools so seductive.

Two cases of infected noses and accessory sinuses came under my notice from this pool, and prompted me to write this letter, as I feel that the hygienic side of such pools has often been, and may again, be overlooked in their construction.

I am, Sir, yours faithfully,

BEAUMONT H. COMERFORD, M.D., D.P.H.

Chester-square, S.W., July 30th, 1929.

To the Editor of THE LANCET.

SIR,—Your annotation on this subject last week (p. 182) has interested me, although its meritorious aloofness rather irritates me at the moment when one of my own children, as a sequel to bathing in a public swimming bath, is recovering from a mastoid operation, in spite of a prompt paracentesis of the intervening acute ear. Nor is my irritation lessened by the fact that my kind specialist colleagues seem to have no doubt of the frequency of these disasters, even in children who have perfectly healthy throats.

If your suggestion is true that in the purification of bathing places "more attention has been paid, as evidence of contamination, to the intestinal flora of the *Bacillus coli* group, than to the pyogenic organisms which more frequently attack the ears," it would seem that the supervision of these places is conducted on lines ten years out of date, and that it is necessary to impress the public health authorities with the great importance of the post-war streptococcus. Further, it would be interesting to know if any special measures are undertaken to prevent excessive contamination of swimming baths in times of great heat and shortage of water.

I am, Sir, yours faithfully,

August 28th, 1929. F.R.C.P.

AN INHERITED TENDENCY TO SUPERNUMERARY DIGITS.

To the Editor of THE LANCET.

SIR,—The following example of heredity in the appearance of supernumerary digits seems to be of interest.

My wife, who has perfectly normal hands and feet (as also have I), gave birth three months ago to a female child which had an extra thumb on each hand and an extra great toe, webbed with the normal on the left foot. My wife's sister was born with an extra thumb on her right hand. One other brother and a sister had normal hands. My father-in-law, his brother and his sister all had a normal number of digits, but the thumbs in all cases were long and tapering, look more like index-fingers and have not the full range of movement of the normal thumb. His mother and her brothers and sisters all, so my information goes, had precisely the same abnormally-shaped thumbs, but had no "extras." Going back one further generation, my wife's great-grandmother had extra thumbs on both hands. I do not know if she had any abnormality of the feet.

Apparently, therefore, the inherited tendency passed over two generations, only showing itself as a slight deviation in all cases from the normal in the shape of the thumbs; affected the next in one individual only; and was passed down to yet another in an indirect fashion.

I should be glad to have the comments of an expert in Mendelism on this sequence and for a forecast as to the prospects of future individuals exhibiting the characteristic.

For obvious reasons I prefer to sign myself

Yours faithfully,

July 29th, 1929. PHALANX.

VICTORIA INFIRMARY, NEWCASTLE-ON-TYNE.—The report for 1928 shows that 14,409 in-patients, whose average stay was 15·1 days, were treated. The accident cases totalled 20,657, of which 1301 were motor casualties; 436 of them were admitted to the wards. The number of beds available, including 30 at the Innes Hopkin's Memorial Home at Ryton, is 572, but every day in the year the normal number of beds has been exceeded by 28, and on some occasions 80 more beds have been occupied than the number for which the wards were planned. The nurses' home is to be extended by 150 bedrooms, 100 nurses being at present housed elsewhere. The medical staff are pressing for the establishment of a number of paying beds in the infirmary extension vacated by the Ministry of Pensions.

Medical News.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—At an ordinary meeting of the College, held on July 25th, with Sir John Rose Bradford, the President, in the chair, the following officers of the College and members of committees were elected for the ensuing year :—

Censors : Dr. Robert Hutchison, Dr. James Collier, Dr. R. A. Young, and Dr. Cecil Bosanquet. *Treasurer :* Dr. S. P. Phillips. *Registrar :* Dr. Raymond Crawfurd. *Harveian Librarian :* Dr. Arnold Chaplin. *Assistant Registrar :* Dr. R. O. Moon. *Library Committee :* Dr. H. R. Spencer, Dr. R. T. Williamson, Dr. Hector Cameron, and Dr. C. J. Singer. *Curators of the Museum :* Dr. H. R. Spencer, Dr. C. E. Lakin, Dr. Hugh Thursfield, and Dr. C. F. T. East. *Finance Committee :* Dr. H. Morley Fletcher, Sir John Broadbent, and Dr. L. S. T. Burrell.

The following were appointed examiners :—

Chemistry : Mr. H. W. Cremer and Mr. W. B. Tuck, D.Sc. *Physics :* Mr. J. H. Brinkworth and Mr. D. Orson Wood. *Practical Pharmacy :* Dr. W. J. Adie, Prof. W. E. Dixon, Dr. Philip Hamill, Dr. Newman Neild, and Dr. V. J. Woolley. *Physiology :* Prof. B. J. Collingwood and Prof. Swale Vincent. *Pathology :* Sir Frederick Andrewes and Dr. Charles Bolton. *Anatomy :* Prof. Duncan Blair. *Medical Anatomy and Principles and Practice of Medicine :* Sir Percival Hartley, Dr. W. J. Fenton, Dr. A. E. Russell, Dr. Cecil Wall, Prof. Frederick Langmead, Dr. E. A. Cockayne, Dr. E. P. Poulton, Dr. D. H. de Souza, Dr. Albert Ramsbottom, Dr. A. C. D. Firth, Dr. F. M. R. Walshe, and Dr. E. Bellingham Smith. *Midwifery and Diseases peculiar to Women :* Dr. Eardley Holland, Dr. J. B. Banister, Dr. Carlton Oldfield, Dr. Malcolm Donaldson, and Mr. A. C. Palmer. *Public Health :* (Part I.) Dr. Roche Lynch and (Part II.) Dr. Charles Porter. *Tropical Medicine :* Prof. J. C. G. Ledingham and Dr. Harold Scott. *Ophthalmic Medicine and Surgery :* Dr. Grainger Stewart. *Psychological Medicine :* (Part I.) Dr. Edward Mapother. (Part II.) Dr. Porter Phillips and Dr. Gordon Holmes. *Laryngology and Otology :* Dr. Donald Rose Paterson. *Murchison Scholarship (1930) :* Dr. Gordon Holmes and Dr. Letheby Tidy.

Dr. Letheby Tidy was elected representative of the College on the General Medical Council in succession to Sir Farquhar Buzzard, and Sir Ewen Maclean a representative on the Advisory Medical Board of the University of Wales.

The Baly medal for distinction in the science of physiology was awarded to Dr. E. D. Adrian, F.R.S., and the Bisset-Hawkins medal for advancing sanitary science and public health to Prof. Edward Mellanby, F.R.S. The Murchison Scholarship was awarded to Ian G. W. Hill, M.B., of Edinburgh University. Prof. J. B. Leathes, F.R.S., was appointed to deliver the Harveian oration, and Prof. W. E. Hume the Bradshaw lecture in 1930. Sir Maurice Craig was appointed a delegate to the Conference of the National Council of Mental Hygiene to be held in October, and Dr. Maurice Davidson a delegate to the Fifteenth Annual Conference of the National Association for the Prevention of Tuberculosis at Newcastle-upon-Tyne in October.

The following further appointments were announced : Dr. Andrew Balfour as FitzPatrick lecturer for 1930 ; Dr. Carey Coombs as Lumleian lecturer for 1930 ; Dr. Donald Hunter as Goulstonian lecturer for 1930 ; Prof. J. J. R. Macleod, F.R.S., as Oliver-Sharpey lecturer for 1930 ; Dr. L. S. T. Burrell as Mitchell lecturer for 1930 ; and Prof. Matthew J. Stewart as Croonian lecturer for 1931.

The thanks of the College were voted to Sir Wilmot Herringham and Dr. John Fawcett for their valuable and lengthy services as representatives of the College on the Senate of the University of London.

The President nominated a committee for the preparation of a new edition of the official "Nomenclature of Diseases."

Having satisfied the Censor's Board the following were admitted Members :—

William W. Barraclough, Richard A. Brews, James K. Cameron, Geoffrey P. Chandler, Albert Coleman, Frederick M. M. Eyton-Jones, Kenneth A. Gilchrist, Frederick C. Golding, John S. Harris, Jack Hartsilver, Aubrey J. Lewis, George E. Lewis, Charles W. Mackenzie, William F. T. McMath, Natwar Jalsing Modi, Francis J. Niall, Douglas A. Robertson, Raghunath Saran, Cedric W. Shaw, Gordon M. Tallent, and Geoffrey T. Todd.

At the same meeting of the Comitia licences to practise were granted to 140 candidates (133 men and 16 women) who have passed the final examination of the Conjoint Board in Medicine, Surgery, and Midwifery, and have complied with the by-laws of the College. The following are the names and medical schools of the successful candidates :—

C. Abraham, Univ. Coll. ; S. Annaswami, Madras ; M. A. E. Anous, Cairo and King's Coll. ; S. W. K. Arundell, Middlesex ; Nancy M. Badeley, Royal Free ; C. P. Bailey, Cambridge and St. George's ; E. F. Barnardo, Cardiff and London ; D. W. Bawtree, Cambridge and St. Thomas's ; D. R. Belletty, Calcutta and Middlesex ; M. J. Bennett-Jones, Liverpool ; H. J. W. Bergh, St. George's ; W. R. Bett, St. Bart.'s ; P. M. F. Bishop, Oxford and Guy's ; R. M. Bolam, Cambridge and Durham ; J. J. Boulle, London ; J. H. Boultbee, Liverpool ; K. J. Box, St. Thomas's ; Bertha A. Briant, Royal Free ; C. E. Brierley, Cardiff and Bristol ; H. P. Brody, Sheffield ; E. A. Butterworth, St. Mary's ; V. I. C. Cadogan, Univ. Coll. ; E. H. Capel, Middlesex ; F. S. Cliff, Univ. Coll. ; F. T. Clive, St. Thomas's ; C. L. Collins, Cambridge and St. George's ; P. A. Cooper, Univ. Coll. ; W. J. Cotton, Oxford and Guy's ; J. P. Crabtree, Manchester ; S. T. Crowther, Cardiff ; P. Dalzell, St. Bart.'s ; A. C. Dawes, King's Coll. ; Catherine Day, Royal Free ; Jessie E. Dodds, Sheffield ; C. E. Dolman, St. Mary's ; W. J. L. Downing, Middlesex ; G. Duckworth, St. George's ; T. F. H. Duffell, Birmingham ; D. H. A. Edmondson, Liverpool ; L. M. Edwards, Cardiff and St. Bart.'s ; J. L. Egan, King's Coll. ; Cordelia H. England, Cambridge and King's Coll. ; I. Q. Evans, Cardiff and St. Bart.'s ; M. D. A. Evans, Cardiff and Univ. Coll. ; R. G. P. Evans, Middlesex ; D. Ezekiel, Charing Cross ; R. B. H. Falchney, Liverpool ; M. Farid, Birmingham ; W. J. Ferguson, Guy's ; J. A. Fernandez, Univ. Coll. ; K. S. Fitch, Guy's ; S. K. Foster, Leeds ; W. W. Fox, Manchester ; A. W. Franklin, St. Bart.'s ; A. Freitag, Cracow and Charing Cross ; R. L. Frost, Guy's ; Ruth C. Galletly, Royal Free ; S. Garson, St. Bart.'s ; N. D. Gerrish and J. J. J. Giraldi, Bristol ; Elizabeth L. Haden, Univ. Coll. ; Hafizuddin, Agra and Charing Cross ; Nellie M. E. Hallinan, Charing Cross ; Margaret L. Homburger, Royal Free ; A. G. J. Harris, Cambridge and St. Bart.'s ; R. L. H. Harris, St. Bart.'s ; F. Hawking, Oxford and St. Bart.'s ; Dora M. Hill, Charing Cross ; R. E. Holmes, London ; I. P. G. Howells, Cardiff and St. Mary's ; W. V. Howells, Cambridge and London ; J. M. Hulett, Guy's ; Laura F. Hutton, Charing Cross ; D. E. Hyman, Manchester and Charing Cross ; K. G. W. James, King's Coll. ; S. K. Jatar, Bombay and London ; A. N. Jones, Guy's ; D. S. Jones, St. Bart.'s ; H. H. Kenshole, Cardiff and Guy's ; T. H. Khan, Calcutta and King's Coll. ; C. W. Kidson, Birmingham ; S. Knight, Univ. Coll. ; M. Kokia, Westminster ; M. Kremer, Middlesex ; J. Libman, Liverpool ; F. J. G. Lishman, Univ. Coll. ; M. Luckeenarain, Univ. Coll. ; S. D. McClean, Guy's ; W. H. McMenemey, Oxford and St. Bart.'s ; A. H. M. McMullan, Birmingham ; R. G. Mayer, Bristol ; R. B. Mayfield, Cambridge and St. Thomas's ; D. A. Metcalf, Cambridge and London ; V. L. Misso, King's Coll. ; S. N. Mistri, Bombay and London ; W. J. Moffat, Cambridge and St. Thomas's ; A. B. Moffatt, Manchester ; G. B. Mobile, Bombay and Guy's ; R. D. Morgan, Cardiff and Middlesex ; Q. St. L. Myles, Oxford and St. Thomas's ; T. Nallainathan, Ceylon and Univ. Coll. ; R. A. Nash, Guy's ; E. J. Neill, St. Bart.'s ; P. L. Nirula, Punjab ; F. E. Norris, London ; S. W. K. Norris, Birmingham ; L. J. O'Loughlin, Manchester ; H. J. Partington, Liverpool ; Penelope A. Peach, Royal Free ; W. Pearce, Leeds ; A. L. Pereira, St. George's ; R. B. Pringle, Cambridge and St. Thomas's ; G. E. A. Prins, Calcutta and St. Mary's ; C. B. Prowse and W. Radcliffe, Cambridge and St. Bart.'s ; B. Rait-Smith, St. Bart.'s ; Florence Ram, Sheffield and Cambridge ; B. V. P. Reddy, Bombay and London ; W. H. Reynolds, Cardiff ; P. J. Richards, Cambridge and St. Bart.'s ; K. M. Robertson, St. Thomas's ; J. A. Robson, St. Bart.'s ; Irene H. Rogers, King's Coll. ; H. L. Rogerson, St. Bart.'s ; I. A. Sabri, Cairo and St. Bart.'s ; R. M. Sargent, Univ. Coll. ; C. K. Soonce, Liverpool ; J. M. Scott, St. Bart.'s ; R. P. W. Shackleton, Cambridge and St. George's ; Everell M. Shipham, Royal Free ; S. Simon, Leeds ; A. R. Smith, St. Thomas's ; W. H. B. Spoor, Cambridge and Bristol ; L. Stirling, London ; A. G. C. Taylor, St. Thomas's ; E. W. Thompson, Manchester ; D. J. Turnbull, London ; J. O. B. van Langenberg, Ceylon and Middlesex ; M. H. Wace, St. George's ; J. V. Walker, Birmingham ; R. Warnecke, Adelaide and London ; J. A. White, St. Mary's ; J. O. Williams, St. Bart.'s ; J. K. Willson-Pepper, Cambridge and St. Thomas's ; Camilla Wiseham, Royal Free ; M. G. Woolf, Cape and St. Thomas's ; L. C. Wright, Manchester ; P. Yarmarko, Manitoba and Middlesex ; and D. J. Young, Middlesex.

The undermentioned diplomas were conferred (jointly with the Royal College of Surgeons) upon the following candidates :—

Diploma in Public Health.—K. P. Ankle-aria, D. D. Bhargava, D. L. Brown, H. A. Bulman, Helen Banistead, K. Cathiravelu, K. B. Chakravarti, A. N. Chatterji, M. Das, A. W. H. Donaldson, D. C. Farquharson, Loveday S. Farquharson, J. W. Fisher, L. Fourie, Hilda M. Garlick, D. Hughes, A. T. Jones, Margaret M. McDowall, Aileen I. McMahon, A. Macmillan, H. H. Mahmood, A. J. Mhatre, S. Mozumder, Joan Nixon, J. D. Robertson, A. S. Simpson, G. Singh, W. S. Slater, J. H. Stritch, R. Watson, Edith S. Williamson, and Frances M. Yule.

Diploma in Ophthalmic Medicine and Surgery.—Agnes L. Adam, B. Alexander, P. K. Banerjea, W. A. Briggs, R. D. W. Butler, S. N. Cooper, V. A. P. Costobadie, T. Edmunds, Julia M. Fleming, A. A. Gibbons, S. L. Goorin, I. C. Fraser, J. R. McClean, N. Manson, R. S. Marya, M. D. Nunan, P. Pattabhiramaiya, A. M. Ponnambalam, C. S. V. Ramanan, K. Sen, L. B. Somerville-Large, B. R. Tandan, M. Tree, T. K. Uttam Singh, D. G. Vyas, and G. B. White.

Diploma in Psychological Medicine.—Leonard Porter, Flora H. McCalder, Viola [illegible] Cameron, Ruby T. Carr, S. W.

Davies, J. H. Ewen, E. A. Haslam-Fox, J. E. S. Lloyd, Seringapatam V. S. Rao, and Kathleen M. Todd.

Diploma in Laryngology and Otology.—Bodh Raj. Chaudhri, Patrick Hickey, G. J. Hutchison, Rajnarain Kacker, W. A. Kerr, K. S. May, R. F. Paterson, C. L. Rosenfield, and Gobind Vaishnavi.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH.—At a meeting of the College on July 23rd, with Mr. Alexander Miles, the President, in the chair, the following 27 successful candidates (out of 81 entered) who passed the requisite examinations between March 21st and 28th were admitted Fellows:—

George Brown, Eva Taylor Cairns, John Campbell, Kewal Ram Chaudhri, Douglas Bannerman Craig, Ross Alfred Grant, Guthrie Yoehlee Graves, Thomas Paterson Gill, David Hardie, Arthur Taylor Henry, Reginald Stuart Jones, Ganesh Das Kapur, John Kerr Ritchie Landells, Donald Percy McDonald, George Henry Mohony, Ma Yin May, Andrew Patrick, William Valentine Semple, William Stewart Shearer, Balwant Singh, Narain Singh, William Collis Spackman, Robert Scott Stevenson, George Munro Sturrock, Alan Boardman Taylor, Maxwell Kidger Tucker, and George Sydney Thompson

Dr. Hari Prakash Lal obtained the diploma of Licentiate of the College.

The Ivison Macadam Memorial Prize has been awarded after a competitive examination in Organic Chemistry to Mr. C. D. Campbell.

UNIVERSITY OF GLASGOW.—It is announced that Sir Donald MacAlister will retire in October from the offices of Principal and Vice-Chancellor of the University.

UNIVERSITY OF LEEDS.—On July 23rd the honorary degree of D.Sc. was conferred on Dr. C. H. Mayo of Rochester, Minnesota.

ST. MARY'S HOSPITAL.—Lord Iveagh has promised to give £20,000 towards the extension of the St. Mary's Hospital Therapeutic Inoculation Department which is under the direction of Sir Almroth Wright, F.R.S. This sum will be paid in seven annual instalments and the hospital will thus be able to claim income tax and surtax so that over £30,000 will be available for the building of a pathological institute beside the hospital.

WALLINGFORD DISTRICT HOSPITAL.—The Morrell Memorial Hospital, so named after Miss Mary Morrell, the founder in 1879 of Wallingford Cottage Hospital, a nurse who died from septic poisoning contracted in her work, was last week superseded by a new District Hospital. The building contains 18 beds in three wards, and two private wards, and is equipped with modern appliances.

Dr. Arthur Edward Giles, consulting surgeon to the Chelsea Hospital for Women and gynæcologist to the Prince of Wales General Hospital, Tottenham, has been elected Master of the Drapers Company. He is the first member of the medical profession to fill the office of Master of this Company, whose records go back to the fourteenth century.

DONATIONS AND BEQUESTS.—The late Mr. Frederick Dempster-Smith, of London and Bournemouth left £25,000 to the Governors of St. Bartholomew's Hospital for the endowment of a ward in memory of his late friend William James Marriage ("Sol"), a corporal-major in the Household Battalion, who was killed in France, to be called the Sol Memorial Ward.—Mr. George Turner of Edgbaston, Birmingham, left £1,250 to the Birmingham General Hospital, and £1,000 each to the West Bromwich District Hospital, Royal Midland Counties Hospital for Incurables, Leamington, and the Quest Hospital, Dudley.—Mr. Elias Sumner Berry of Southport left £1000 to the Preston and County of Lancaster Queen Victoria Royal Infirmary to name an "Oswald William Berry Bed" in memory of his son who was killed in action in France.—Mr. Alfred Thomas Johnson Ward [illegible] [illegible]ton, Bristol, left £500 each to Bristol Royal I[illegible] General Hospital, Bristol Eye Hospital, an[illegible] of Industry for the Blind, Westbu[illegible] (Elizabeth Ann Phippen) Esme Gordon [illegible] London, left £400 to St. George's Hospit[illegible] Infirmary, £250 each to the London [illegible] Hospital, Roehampton, S.W., St. Dunstan['s] [illegible] Sailors and Soldiers, National Society [illegible] of Cruelty to Children, [illegible] Dumb [illegible] After legacies to servant[s] [illegible] residue of her property [illegible] Hospital, St. Tho[illegible] Cancer Hospital, Fu[illegible] Children, Gt. Ormond [illegible] Blind, and the Dist[illegible] Mr. Alfred Norman D[illegible] building extension f[illegible]

CHARING CROSS HOSPITAL NURSES' HOSTEL.—St. Mary's Convent, Haverstock Hill, has been purchased by Charing Cross Hospital as the site of a new nurses' hostel. The spot is easy of access from the hospital by the Hampstead Tube.

LONDON HOSPITAL SUNDAY FUND.—The Council of this Fund reports that the amount received in the past year was £78,130, being £3300 less than in the previous year. Of this sum £77,940 is to be distributed among 165 hospitals, 82 dispensaries, and 35 nursing associations.

EAST HAM WAR MEMORIAL HOSPITAL.—On Wednesday in last week the Queen opened this general hospital, which is a memorial to 2000 local men who fell in the war. Its genesis was the East Ham Cottage Hospital, founded in 1902 with 25 beds, which has now been converted into children's wards. The new building contains 100 beds and has cost £75,000.

HOSPITAL OF ST. JOHN AND ST. ELIZABETH.—This hospital in Grove End-road, St. John's Wood, which was founded in 1856 by four of the Sisters of Mercy who had been working with Miss Florence Nightingale, last year treated 1542 in-patients—an increase of 177 over the preceding year—of whom 321 were private patients. There were 1131 operations, the X ray department has been enlarged, and the rebuilding of the first portion of the nurses' home is approaching completion. The second portion is urgently needed, the old building being in bad structural condition. The hospital contains six wards and there are 18 rooms for private patients, including two for persons of small means, for which the charge is £2 10s. per week. Eight rooms, moreover, are reserved for priests and nuns of the Roman Catholic diocese of Westminster, but the hospital is entirely undenominational. The total weekly cost per patient is £4 0s. and of the £25,520 spent during the year only £2835 was derived from investments. There are 134 beds and the hospital is a training school for radiographers and for Roman Catholic nurses.

NATIONAL ASSOCIATION FOR THE PREVENTION OF TUBERCULOSIS.—At the annual meeting last week the Council reported that the special appeal for £100,000 had produced £110,941. From this money grants have been made to the Burrow Hill Sanatorium Colony, at Frimley, and towards the establishment of workshops for tuberculous patients. The Burrow Hill Colony is an experimental scheme for providing treatment and technical education for tuberculous boys from 14 to 19 years old under medical and scholastic supervision (see THE LANCET, 1929, i., 673). It contains 80 beds, 60 of which are provided for arrested cases; the other 20 are in a separate block for patients in the earlier stages of the disease. The institution is primarily intended for youths suffering from pulmonary tuberculosis in whom permanent arrest of the disease is ultimately likely to be secured, and who are in need of, and temperamentally fitted for, technical education, which consists of gardening and clerical work. For the rest, four medical men have been engaged as Medical and Assistant Medical Commissioners who, in addition to general propaganda work, act as lecturers. Three motor vans, with interesting exhibits, including films, have been equipped, and illustrated lectures have been given in many parts of England and Scotland. The educational work is organised by Dr. William Brand, the Medical Commissioner.

CHADWICK TRUST SCHOLARSHIPS.—In view of the quality and number of the applications received for the two Chadwick travelling scholarships in sanitary science and municipal engineering, the trustees have decided to make three instead of two appointments.

The scholarships are of £400, tenable for one year, [illegible] the successful candidates are: Francis Bach, M.D. Ox[illegible] Out-Patient Medical Officer of the National Heart Hosp[illegible], to whom a scholarship is granted "for the purpose of inv[e]sti[gating] [illegible] the environmental and other causes of rheumatic [illegible] and their influence in producing diseases of the [illegible] Edmund A. Elsby, B.Sc., of Liverpool University, [illegible] [st]udy and collect data respecting the removal of [illegible] from the atmosphere in factories; and John B. [illegible], Glasgow University, who will study sewage [illegible] with special regard to trade waste.

[illegible] Gift Scholarship of £100, to enable the [illegible] study and present a scheme [illegible] and efficient system of heating [illegible] to a hall seating about 1000 [illegible] [illegible]ed and a set of residential [illegible], is offered for competition. [illegible] [Briti]sh subjects, should apply in [illegible] [illegible]th and Sept. 30th to the [illegible] at 204, Abbey House, West-

ENLARGEMENT OF BOSCOMBE HOSPITAL.—Four new wards for men, containing a total of 12 beds, were opened last week at the Boscombe branch of the Royal Victoria and West Hants Hospital. The largest ward, of six beds, is named after the late Mr. Augustus Gould, one of the benefactors of the Hospital.

A NURSERY SCHOOL IN LIVERPOOL.—The Liverpool Education Committee have approved a resolution by the Elementary Schools sub-committee recommending the City Council to authorise the establishment of an experimental nursery school to accommodate about 200 children between the ages of 2 and 5 years. The aims of the school are stated to be: (a) To foster all-round healthy physical development by providing a favourable environment, by training in hygienic habits, and by encouraging free activity; (b) to lay the foundations of intellectual development by providing a great variety of interesting experiences, by special training, and by such simple instruction as is suitable; and (c) to lay the foundations of character by the inculcation of self-respect and consideration for others. Formal lessons will have no place in the curriculum. The children will be taken daily to and from their homes. The cost to the ratepayers will be about £17 per head per annum, which is less than half the expense of children at Corporation day nurseries.

SUN-BATHING IN PUBLIC PARKS.—On July 29th Mr. George Lansbury, the First Commissioner of Works, received a deputation including Dr. C. W. Saleeby, Sir Arbuthnot Lane and Sir Alfred Fripp, which put forward, pleas for extended facilities for sun-bathing in public parks. Sir Richard Paget outlined a scheme for a permanent sun-bathing colonnade on the west bank of the Serpentine in Hyde Park, and appealed to the Department to encourage the granting of permission all over the country for the wearing of bathing shorts. In his reply, Mr. Lansbury referred to the fundamental need for providing more sunlight in the homes of the people, and spoke of the care which was taken to see that those in mental homes and prisons should get plenty of light and air. Similar regulations were made for children in class rooms. The only time when the law did not insist on the proper cubic space was when the children were asleep, which seemed to him one of the maddest things in the world. He hoped that legislation to be introduced in the autumn would deal with the slum problem so drastically that no child could in future be born in an underground basement.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

ALL SAINTS' HOSPITAL, Vauxhall Bridge-road, S.W. Special Course in Urology. Afternoons and evenings until the end of August. Further information from the Secretary, Fellowship of Medicine.

Appointments.

GREGORY, J. C., L.R.C.P. Lond., M.R.C.S., has been appointed Obstetric House Surgeon at University College Hospital.

Certifying Surgeons under the Factory and Workshop Acts: HENDRON, M. F., M.B., Ch.B. Belf. (Croston, Lancs.); and MOWAT, J., M.B., Ch.B. Glasg. (Chapel-en-le-Frith, Derby).

Vacancies.

For further information refer to the advertisement columns.

Aylesford, British Legion Village, Preston Hall Sanatorium.—Second Asst. M.O. £200.

Barnsley, Beckett Hospital and Dispensary.—H.P. £140.

Barrow-in-Furness, North Lonsdale Hospital.—H.S. £150.

Basingstoke, Park Prewett Mental Hospital.—Jun. Asst. M.O. £350.

Birkenhead General Hospital.—Cas. S. £100.

Bradford, Royal Eye and Ear Hospital.—Jun. H.S. £120.

Brighton, Royal Sussex County Hospital.—H.S. £150.

Burton-on-Trent, General Infirmary.—2nd Res. H.S. £150.

Bury Infirmary.—Sen. H.S. 2nd H.S. Also 3rd H.S. At rate of £200, £175, and £150 respectively.

Cardiff Royal Infirmary.—Aural H.S. At rate of £75.

Carlisle, Cumberland Infirmary.—H.P. Also H.S. to special Departments. Each at rate of £165.

Cheshire Joint Sanatorium, Market Drayton, Salop.—H.P. £250.

Colonial Medical Services.—Vacancies.

Dudley, Guest Hospital and Eye Infirmary.—H.S. £150–£175.

East Ham Memorial Hospital, Shrewsbury-road, E.—Res. M.O. At rate of £150.

Exeter, Royal Devon and Exeter Hospital.—Asst. H.S. At rate of £100.

Glasgow, Govan District Asylum.—Jun. Asst. M.O. £325.

Great Yarmouth General Hospital.—Sen. H.S. £150.

Ilford Emergency Hospital.—Sen. and Jun. H.S.'s.

Infants Hospital, Vincent-square, Westminster.—Anæsthetist.

Ipswich, East Suffolk and Ipswich Hospital.—H.S. At rate of £120.

Kidderminster and District General Hospital.—H.S. At rate of £150.

Liverpool, Ministry of Pensions Hospital for Epileptics, Maghull.—Jun. M.O. £300.

Liverpool Open Air Hospital for Children, Leasowe.—Jun. Res. M.O. At rate of £200.

Liverpool, Royal Liverpool Children's Hospital.—Res. M.O. for Heswall Branch. At rate of £120. Also 2 Res. H.P.'s and 2 Res. H.S.'s for City Branch, Myrtle-street. Each at rate of £60.

London Female Lock Hospital, 283, Harrow-road, W.—H.S. At rate of £150.

London Homœopathic Hospital, Great Ormond-street, W.C.—Asst. Surgeon for Diseases of the Eye.

Lowestoft and North Suffolk Hospital.—H.S. £120.

Manchester, Ancoats Hospital.—Orthopædic H.S. Also H.P. Each at rate of £100.

Manchester Royal Infirmary.—Jun. H.S. £100.

Middlesex Hospital Medical School, W.—Second Demonstrator in Physiology. £250.

Miller General Hospital, Greenwich-road, S.E.—Hon. P. to Skin Dept. Also Cas. O. At rate of £150.

Northwood Mount Vernon Hospital.—H.S. At rate of £40.

Nottingham General Hospital.—Asst. Res. Cas. O. At rate of £150.

Nottingham Children's Hospital.—Res. H.S. At rate of £150.

Oldham County Borough Education Committee.—Asst. Schools M.O. £600.

Richmond Royal Hospital.—Jun. H.S. £100.

Rotherham, County Borough of.—Deputy M.O.H., &c. £650.

Rotherham Hospital.—H.P. £180.

Royal Air Force Medical Service.—M.O.'s.

Salisbury General Infirmary.—Res. H.P. £150.

Scarborough Hospital and Dispensary.—Two H.S.'s Each at rate of £125.

Shipley, Urban District of.—M.O.H. £800.

Swansea Hospital.—H.S. £150.

Weston-super-Mare, Queen Alexandra Memorial Hospital.—Res. M.O. £150.

West Riding of Yorkshire.—County M.O.H. £1,600.

Woolwich and District War Memorial Hospital, Shooters' Hill, S.E.—Jun. H.S. At rate of £125.

Worcester General Hospital.—Sen. and Jun. Res. M.O.'s. £180 and £120, respectively.

The Chief Inspector of Factories announces vacant appointments for Certifying Factory Surgeons at Bristol (Glos.), and Brentford and Ealing. (Middlesex).

Births, Marriages, and Deaths

BIRTHS.

BATTEN.—On July 27th, at a nursing home, Hampstead, the wife of Lindsey W. Batten, M.B., M.R.C.P., of a son.

HEGGART.—On July 18th, at Victoria Cottage, Rowhedge, Colchester, the wife of Dr. John E. Heggart, of a son.

DEATHS.

BOTT.—On July 21st, at The Bungalow, Percy road, Broadstairs, Stanley Bott, M.D., L.R.C.P., M.R.C.S., aged 60, late of Tower House, Caistor, Lincs.

GRAVELY.—On July 24th, at Cowfold, William Homewood Gravely, M.R.C.S., L.R.C.P.

LEES.—On July 23rd, Kenneth Arthur Lees, F.R.C.S., formerly of Weymouth-street, W.

LUCAS.—On July 23rd, Thomas John Rashleigh Lucas, C.B., colonel (retired), A.M.S., late of Bury-street, St. James's, S.W., son of the late George Lucas, of Ballinadee, Co. Cork, Ireland, aged 71.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

INDEX TO "THE LANCET," VOL. I., 1929.

THE Index and Title-page to Vol. I., 1929, which was completed with the issue of June 29th, is now ready. A copy will be sent gratis to subscribers on receipt of a post-card addressed to the Manager of THE LANCET, 1, Bedford-street, Strand, W.C. 2. Subscribers who have not already indicated their desire to receive Indexes regularly as published should do so now.

Notes, Comments, and Abstracts.

FOUR MILLENNIUMS OF CHINESE MEDICINE.

By K. C. WONG.

(Concluded from p. 208.)

IV. THE MODERN OR TRANSITIONAL PERIOD.

Transitional is a fitting term for the Tsing Dynasty, for during this period Chinese medicine showed a gradual and perceptible decline until 1805, when it received a fresh shock by the introduction of Western Medicine. Struggling under the yoke of an alien race naturally, the scientific advancements made could not be compared with those made in other Dynasties. Emperor Kien Lung, however, was a great patron of literature, and as an outcome of his encouragement the "Golden Mirror of Medicine" was produced. This is a sort of encyclopædia of medicine and surgery compiled by a committee of doctors at the order of the Emperor. It summarises the corrections and revisions of many ancient works and epitomises all the recent methods and discoveries. The "Golden Mirror" is recognised as a standard work.

An interesting figure of this time was Wang Hsun-shan, who is sometimes styled the reformer of Chinese medicine. He was the author of "Correction of Medical Errors," a remarkable little work which contains many ingenious opinions concerning anatomy and pathology, based on 42 years medical experience, and the observations of 30 decapitated human bodies. Unfortunately the corrections are erroneous. The book, though of not much scientific value, is full of original ideas, the opinions on the causation of hemiplegia, and on the brain as the organ of thought, being especially interesting.

Vaccination.—The Western method of vaccination was introduced into China in May, 1806. It was brought over from the Philippines to Macao, whence it spread to Canton and other places. It is remarkable that a century before Jenner's epoch-making discovery the Chinese seem to have had an idea of vaccination, for in the "Synopsis of Ancient Herbals" the use of fleas from the cow for the prevention of small-pox is mentioned—is it wholly impossible that the fleas of a cow affected with variola, when taken by the mouth, might have an effect analogous to that of vaccination? That this treatment was once popular suggests that there may be some efficacy in it; if so, and if there had been a Chinese Jenner to follow up the clues millions of lives might have been saved.

WESTERN MEDICINE.

In 1805 Dr. Hobson, an Englishman, came to Canton to be followed later by Drs. Parker, Kerr, and others. Silently and steadily these pioneers of Western medicine worked their way, and in spite of the proverbial conservatism of the people it has now gained a firm foothold. Only a few historical landmarks will be given.

The first Chinese who studied foreign medicine abroad was Wong Cheuk Hing. A native of Canton he was born in 1882, and obtained his English education in Macao and Hong-Kong. In 1840 he followed a Mr. Brown to America for further studies where he stayed for four years. After his graduation in literature he went over to Edinburgh to study medicine, receiving his degree in 1855. Two years later he returned to China and worked in the various hospitals in Hong-Kong and Canton until his death in 1878. With the return of a number of graduates from Japan in 1899 a new situation was created. Hitherto all Western medical work was entirely in the hands of European and American doctors. Through the writings and influence of this new body of men, Japanese medicine, and especially Japanese medical terms, became popular. They founded schools and hospitals and gradually developed into a new force in Chinese medical matters. Many of them are now holding important positions in the Government.

The new era in modern preventive medicine may be said to have dated from 1911. The great pneumonic plague in Manchuria demonstrated to the people the superiority of Western science as compared with the old native methods for the suppression of plague. Since that time many laws governing the notification of infectious diseases, the standardisation of medical education, the dissection of dead bodies, the registration of medical practitioners, the sale of narcotic drugs, &c., have been passed. In 1914 the National Medical Association of China, which has for its members the most prominent graduates from European, American, Japanese, and Chinese Colleges, was founded. Prior to this teachers and authors had great difficulty in their work because of the lack of uniform scientific terms. In 1915 a Terminology Committee was appointed, consisting of representatives of the Ministry of Education, National Medical Association, Medical and Pharmaceutical Society, Medical Missionary Association, and Kiangsu Educational Association, to determine the terms to be used throughout China. In order to promote public health and sanitation among the masses a joint Council of Public Health Education was formed in 1916 consisting of representatives from the National Medical Association, Medical Missionary Association, Y.M.C.A., Y.W.C.A., and China Christian Educational Association. All these organisations are doing splendid work towards the medical progress of China.

The formal opening of the Union Medical College and Hospital at Pekin on Sept. 15th, 1921, adds another chapter to the annals of medicine in this country. The whole plant covers an area of about 10 English acres and costs approximately five million dollars gold. It is the first medical school in the Orient, not only in the magnificance of its architecture, but also in the completeness of its outfit. Great things are expected of this institution.

The Missionary Doctors.

In conclusion, the highest tribute must be paid to the missionary doctors who were the earliest to found hospitals organise schools, and promote public health and hygiene, &c. They have brought a new light and a new hope to the teeming millions of suffering humanity. Though handicapped by insufficient funds, lack of proper equipment, and other adverse conditions, these men laboured with incessant zeal, gradually gaining ground until Western medicine attained its present position. The institutions they founded are scattered throughout the country. They are not only centres of healing but are also factories of learning, whence, every year, a small army of trained men are sent out to join those in the field to fight the demons of ignorance and disease. Inspired by the noble efforts of these pioneers, the Government and other public bodies have started to establish hospitals and schools of their own. Some of these are well organised and fully equipped. In the years to come the work of the missionary doctors may be eclipsed and eliminated. But their great contribution to medical advancement and to human progress in China will for ever remain.

CONCLUSION.

Such is a brief epitome of medicine as it has existed and been practised in China. While the Chinese anticipated many discoveries, collected a great variety of facts, invented some valuable methods and brought a few to a high degree of excellence, yet they have never pursued a single subject in a way calculated to lead them to final success. The circulation of blood, anæsthetics, X rays, vaccine therapy massage, catheters, hypnotism, hydrotherapy, hygiene, organotherapy, &c., had all been hinted at, but remained barren of results until centuries later Western science stepped in and secured the prize. The field of Chinese medicine is still a veritable virgin soil. There are golden opportunities for research workers to break open the hidden wealth of treasures. The day will come when Chinese medicine will pass through this stage of transition to emerge once more, purified and strengthened, and lead again the medical thoughts of the world.

RATING OF BRIGHTON HOSPITALS,

As the result of action through the Social Service Centre at Brighton, an agreement has just been reached in regard to the assessment of charitable institutions in the town. Strong representations had been made of the great hardships which would be inflicted upon the hospitals if the figures arrived at by the Corporation valuer, when the town was re-assessed under the Rating and Valuation Act, 1925, were allowed to stand. As the result of the representations, the Corporation valuer (Mr. H. P. Nye), in conjunction with Mr. Gerald Eve, have thoroughly reviewed the position. They took into consideration the assured income of the hospitals as against voluntary contributions, and those institutions which depended mostly on voluntary contributions were valued at a proportionately lower figure than those which derived an assured income from grants from State or municipal funds, or from payments by beneficiaries. The result has been as follows, the figures in parenthesis denoting the original assessment, while the other figures show the new assessment as proposed under the Rating and Valuation Act, and those which now stand as the final settlement. :—

	New. £	Final. £
Royal Sussex County Hospital (£175) ..	4,103 ..	2,040
Royal Alexandra Hospital for Sick Children (£48)	1,290 ..	685
New Sussex Hospital (£80)	600 ..	304
Sussex Eye Hospital (£24)	300 ..	162
Sussex Maternity Hospital (£124)	636 ..	364
Sussex Throat and Ear Hospital (£28) ..	450 ..	260
Brighton, Hove and Preston Dispensary (£47)	260 ..	122
Dental Hospital (£24)	90 ..	68

Popular Lecture:

EXPERIMENTS ON FROGS AND MEN.

Delivered before the British Medical Association at Manchester on July 26th, 1929,

BY A. V. HILL, F.R.S.,

FOULERTON RESEARCH PROFESSOR OF THE ROYAL SOCIETY.

MAN is an inveterate experimenter. Those of us who have been happy enough to see small boys at work, who have been small boys ourselves, or indeed are still small boys, will know what joy is found in taking an old alarm clock to bits or a bicycle to pieces, in seeing how fast we can run a hundred yards, in breeding rabbits, pigeons, or canaries, in fixing wireless apparatus together, or, when we are older, in trying a new kind of oil or petrol or even a new kind of medicine. Boys and men, however—by which I mean also girls and women—are not the only experimenters to be found in nature, as any who have watched a kitten or a parrot will know; and experiments made by monkeys have been scientifically studied. Man, however, is the chief experimental animal, both as experimenter and "experimentee." Indeed, in many of man's most joyful adventures he acts in both capacities; he makes experiments upon himself, often to his own great danger or discomfort.

MAN THE EXPERIMENTER.

To run in a Marathon race or to try to swim the Channel, to see how far one can ride a bicycle in 24 hours, to climb to 20,000 feet, to set out to walk (or to fly) to the South Pole, to make a height record in an aeroplane, to dive under the sea, all these involve trials and experiments upon oneself; which is one reason why so many apparently useless feats are performed. Every new adventure on which man has embarked throughout the ages, every change in his social and economic and political condition, has meant experiments upon his bodily frame and organisation, experiments sometimes successful but often followed by disaster.

In learning the use, treatment, and preservation of food he must, unwittingly often, have made millions of experiments upon himself, thousands of them extremely unpleasant, many of them fatal. Without these experiments, however, the present order of civilisation, depending as it does upon a regular supply of food, would have been impossible. When he set out to journey on the sea he experimented on sea-sickness, and later on, as his journeys lengthened, on scurvy and the need of vitamins. When he deserted a natural diet and gathered together in cities he experimented on nutrition and the physiological effects of radiation (or its absence), with rickets as a curious result. When he began to dig deep tunnels, or to work in diving bells or diving suits, he discovered that considerations of the physical solubility of gases in his blood and tissues may affect his well-being, and he invented caisson disease. When he climbed high mountains, or went up in balloons, he discovered mountain sickness, and acclimatisation to it. When he took to rapid manœuvres in aeroplanes he found out that the human factor is a limiting one, that violent acceleration—"centrifugal force"—may play havoc with his circulation and render him suddenly unconscious. Labouring in hot mines, in extremes of climate, with excess or deficiency of sunlight; living on sterilised, preserved, or purified food; breathing quartz dust or carbon monoxide; working with materials which exert a chronic irritation on the skin, or with ultra-violet light, or with X rays and radium; in all such experiments he found limitations to his independence of his external environment; he made experiments upon himself and others, experiments involving ill-health, disaster, and death to many. Even apart from disease, from the experiments which Nature wantonly insists upon making on us, we cannot avoid making experiments on ourselves if we are to do anything new; and, even if we do nothing new, we shall probably find we must make experiments still to discover how to remain just as we are.

NATURE THE EXPERIMENTER.

I am speaking this evening to those, and the friends and relations of those, who spend their lives in mitigating the results of the experiments which Nature makes upon suffering mankind. Some of these experiments involve bacterial infection and, therefore, are, or will be, to some degree avoidable. Others have no known cause, though some day their character too will be revealed. Others are due to functional disturbances in the mechanism—i.e., in the biochemistry and biophysics of the living cells of the body. Some are due to gross lesions which can be seen. Every imaginable ill, great or small, every conceivable torture, physical or mental, you are called upon to witness, and to attempt to alleviate. Some of this suffering is unquestionably due to human folly; some to man's insistence—no doubt for perfectly good reasons—upon living in a civilised industrial state; some to what we call accident—which usually means insufficient skill, or a disregard for human safety. Much sickness is avoidable, and *would* be avoided if only questions of public health and infant welfare were taken seriously enough. Many diseases, however, and their consequences, cannot be prevented altogether, until at any rate we know much more than we do to-day. You can predict the course of the disorder when once it is apparent; you can mitigate its evil consequences; sometimes even you can cure it; but at present you cannot tell us how to avoid it altogether.

Now each of your patients represents an experiment performed by Nature, often apparently a cruel and ruthless experiment, and you—her laboratory assistants—are given a variety of them to witness and to try to learn something from. Nature, however, is an extremely bad experimenter; she is, in fact, the imaginary vivisector of antivivisectionist literature, whose experiments are made without mercy and without apparent cause. So badly and so casually performed are they, so ill-controlled, that it is often impossible for you to reason accurately from them at all. Small wonder that for thousands of years medical knowledge advanced so relatively slowly, when it had to be based only on experiments such as those which Nature provides. For, as all who have tried to reason from experiments have found, these may be good or they may be bad; so well made on the one hand, so carefully thought out and prepared before the event, that one may draw sure and decisive conclusions from them; or, on the other hand, so ill-conditioned, so casually performed, that no certain deduction is possible. In most of Nature's experiments the variables involved are all confused with one another; the factors at work cannot be disentangled; half a dozen functions have been interfered with at one and the same time; the results are not clear cut, and an extraordinary degree of judgment and experience is required before you can reason from them at all.

This cannot indeed be otherwise. To your individual patients you have a duty to perform which is greater than your duty to the rest of mankind. The only way in which the confusion may be avoided is by comparing the results of Nature's casual, random, and complex experiments on human beings with those of simple, properly controlled experiments on living animals. Such a comparison is the means by which in the last few hundred years, and especially in the last seventy-five, medical science has made such startling progress. You can observe, within certain narrow limits prescribed by ethical considerations you can experiment on, man; the idea of the use of criminals for dangerous experiments, common in the past, is repulsive to-day. In any case, fortunately, the supply of criminals would be inadequate! To acquire a real knowledge of the factors at work, these observations, these limited experiments possible on your patients or yourselves, *must* be compared with the results of simpler experiments on animals, in which it is a matter of little moral importance if the patient dies.

THE EXAMPLE OF CLAUDE BERNARD.

Many of you will have read with pleasure and instruction "An Introduction to the Study of Experimental Medicine," by Claude Bernard. As Lawrence Henderson says in the introduction to the English translation: "The discoverer of natural knowledge stands apart in the modern world an obscure and slightly mysterious figure." To some he is a magician; to others he is a sort of stage professor, with blue spectacles and a long beard, forgetful and untidy; to a number (including Mr. Bernard Shaw) he is a criminal or a fool; to the majority he is almost entirely negligible, until the newspapers make some preposterous stunt about him, when he receives unwanted attention for a few weeks. "Whoever fails to understand the great investigator can never know what science really is. . . . Not the least merit of Bernard's book is that we have here an honest and successful analysis of himself at work by one of the most intelligent of modern scientists."

I cannot do better than quote what Bernard says about the experimental method: "Man is metaphysical and proud. He has gone so far as to think that the idealistic creations of his mind, which correspond to his feelings, also represent reality. Hence it follows that the experimental method" (by which of course Bernard means not merely the *making* of experiments, which is easy, but the art and science of experimentation, which is difficult) "is by no means natural to man, and that only after lengthy wanderings in theology and scholasticism has he recognised at last the sterility of such efforts. . . . The human mind has at different periods of its evolution passed successively through *feeling*, *reason*, and *experiment*. First, feeling alone, imposing itself on reason, created the truths of faith or theology. Reason or philosophy, the mind's next mistress, brought to birth scholasticism. At last, experiment, or the study of natural phenomena, taught man that the truths of the outer world are to be found ready formulated, neither in feeling nor in reason. These are indispensable merely as guides: but to attain external truths we must of necessity go down into the objective reality. . . . In the search for truth by the experimental method, feeling always takes the lead: it begets the *a priori* idea or intuition: reason or reasoning develops the idea and deduces its logical consequences. But if feeling must be clarified by the light of reason, reason in turn must be guided by experiment."

In these words lies the philosophy of the great experimental physiologist, whose work and outlook are bearing at last such rich fruit in experimental medicine. It may seem curious that the bearing of that fruit has been so long delayed. Henderson is probably right in seeing in the growth of bacteriology, following on the discoveries of Pasteur, the cause which drew men's attention away for a time from the more fundamental study. The magnificent edifice of bacteriology is not yet complete, but one's mind's eye can grasp already what its dimensions, its plan, its proportions, its significance are to be. Thought is returning to Bernard's conception of medicine as an experimental biological science, of which, as he rightly said, zoological vivisection is, and is likely to remain, an integral part.

Let me take an example from Bernard's own work to illustrate how a few controlled experiments on living animals may shed light on the countless uncontrolled experiments of Nature on living man. The existence of vasomotor nerves, the control of blood-vessels by the innervation of the muscle-fibres that lie around them, are matters of ultimate importance, not only in our understanding of bodily functions, but in dealing with the phenomena of disease. In 1851 Bernard made his first communication on the effect of dividing the cervical sympathetic nerve in the neck of a living animal. The ensuing rise of temperature on the affected side, a surprising and quite unexpected phenomenon, led by a long series of researches directly to our knowledge of the vasomotor system. It is almost impossible, as Michael Foster says, to exaggerate the importance of the result, the influence which it "has exerted, is exerting and in widening measure will continue to exert, on all our physiological and pathological conceptions, on medical practice, and on the conduct of human life. Whatever part of physiology we touch, be it the work done by muscle, be it the various kinds of secretion, be it the insurance of the brain's well-being in the midst of the hydrostatic vicissitudes to which the changes of daily life subject it, be it that maintenance of bodily temperature which is a condition of the body's activity: in all these, as in many other things, we find vasomotor factors intervening." In inflammation and in fever, in shock, in any of the disordered physiological functions which constitute disease, whatever be the tissue, vasomotor influences have to be taken into account.

All this dominant knowledge has come from Bernard's initial experiment in cutting the cervical sympathetic nerve. A simple experiment on a living animal suddenly brought a great light into a field where men had been groping in vain with the help only of clinical observation. The result of the experiment was the first clear light which broke upon the subject: and it was the following up of the teaching of the experiment which supplied the interpretation of the hitherto obscure clinical facts.

As Foster rightly claims, we must insist that the experiment in question was what is called, as though it were a term of abuse, a vivisectional experiment: an experiment which many would prevent us from performing to-day, willing though they be, when they go to the doctor, to profit by similar experiments in the past. Such experiments are sometimes declared to be needless, since the knowledge gained by them *might* be arrived at in other ways. It is true that in the course of time, experiments made by Nature, or by accident, on human beings, *might* have suggested to some quick mind that nerve-fibres do act on blood-vessels, and how they act. The unbiased inquirer will admit this, but he will also acknowledge that up to the day of Bernard's experiments all the experiments which a seemingly cruel Nature had carried out year after year, and day after day, on millions of suffering men and suffering animals, passed before the eyes of eager observers without suggesting anything more than the dimmest idea of such an action of nerve-fibre on blood-vessel. And he will also admit that a single stroke of Bernard's knife—a stroke bringing pain which shrinks into insignificance compared with the pain which it has been the means to spare—laid bare a truth which all Nature's cruel experiments on myriads of men and animals for half a million years had not, in fact, succeeded in bringing to light.

All this our unbiased inquirer will admit. Whatever antivivisectionists may say about the might-have-beens, about the way in which some superhuman intelligence *should* have been able to see the truth without the aid of experiment, there remains the plain, simple historical fact that this discovery, with all its bearing on health and disease, had its origin in Bernard's initial experiment on a living animal. I have recalled, almost without paraphrase, what Foster wrote in 1899. It is no less true in 1929. Would anyone dare to-day, had he the power, to *give* the pain which Bernard's discovery abolished, in order to *save* the pain by which the discovery was made? If so, he may call himself a friend of animals, but he is an enemy of mankind.

THE VALUE OF ANIMAL EXPERIMENTATION: HARVEY AND BERNARD.

We hear so much [illegible]on raised to-day to the use of living animal[illegible] [illegible]ts designed to solve the problems w[illegible] and physiology supply, that one must continue to insist that nearly all fundamental knowledge in the medical sciences has, in fact, arisen from such experiments. In the dedicatory epistle of "De Motu Cordis," addressed to that "most excellent and most ornate man," the President of the College of Physicians in London, William Harvey, speaking of the experiments on living animals by which he had for many years demonstrated the fact of the circulation of the blood, remarked: "Neither do Philosophers suffer themselves to be addicted to the slavery of any man's precepts, but that they give credit to their own eyes; nor do they swear allegiance to Mistress Antiquity, as openly to leave their friend Truth. For as they think them credulous and idle people, who at first sight do receive and believe all things, so do they take them for stupid and senseless that will not see things manifest to the sense, nor acknowledge the light at midday. . . . Likewise all studious, good and honest men do never suffer their minds so to be o'rwhelmed with the passions of indignation and envy, but that they will patiently hear what shall be spoken in behalf of the truth, or understand anything which is truly demonstrated to them; nor do they think it base to change their opinion, if truth and open demonstration so persuade them." If only the precept of these words could be heeded by those who object to the experiments of Harvey and his successors!

When Harvey, as he said, "first applied his mind to observation from the many dissections of living creatures as they came to hand" to find out the nature of the motion of the heart, he "straightways found it a hard thing to be attained, so that he could almost believe that the motion of the heart is known to God alone." At last, however, "using daily more search and diligence, by often looking into many and several sorts of creatures, I did believe I had hit the nail on the head and thought I had gained both the motion and use of the heart, which I did so much desire."

And so, by the vivisection as he says of "toads, serpents, frogs, house-snails, shrimps, crevisses, and all manner of little fishes," together with eels, dogs, swine, doves, chicken embryos, crabs, wasps, hornets, gnats, bees, geese, rats, sheep, adders, lice, swallows, partridges, hens and swans, modern physiology and modern experimental medicine were born. For those who, in Harvey's words, are not "stupid and senseless," who are ready to "acknowledge the light at midday," we have here one of the greatest discoveries of all time; a discovery greater even than that of the circulation of the blood; the discovery that by comparative experiments on "many and several sorts" of living creatures we may reveal the nature and working of man's body, we may increase his power and happiness and wisdom, and cure and protect him from suffering and disease.

This lecture has been entitled "Experiments on Frogs and Men." The physiologist's little friend the frog has been chosen as the general type of the experimental animal, and I have just read you a list of all its colleagues which William Harvey employed in his discovery of the circulation of the blood. In using these various animals he assumed, unconsciously, what we now know to be a fact, the fact (I do not call it the theory) of evolution. He realised, being a sensible person, that the hearts of snakes or crabs, of snails or fishes, do not differ so much from those of the higher animals and man, that an investigation of the former would throw no light upon the latter. There *are* differences of course; no reasonable man supposes that by studying the circulation, or, indeed, any function, in the frog or even in the dog alone, we shall learn enough to make us competent physicians. The differences, however, are often more apparent than real; the fundamental properties of the ultimate living units—that is, of the single cells which build up the various organs—are surprisingly alike. By the methods of comparative physiology, or of experimental biology, by the choice of a suitable organ, tissue or process, in some animal far removed in evolution, we may often throw considerable light upon some function or process in the higher animals, or in man.

THE FURTHER RANGE OF DISCOVERY: DEFICIENCY DISEASES.

I have spoken of two discoveries of the more distant past, those of Harvey and Bernard, which were made by the aid of experiments on animals, discoveries on which the practice of medicine to-day is based. Where would you be if you did not know or would not acknowledge the circulation of the blood? How would your patients fare had you never heard of the control of blood-vessels by nerves? To refer to other discoveries, how safe would surgery be to-day had the researches of Pasteur on animals and their applications by Lister on men never been made? When you take a blood pressure, do you or your patients give full credit to the Rev. Stephen Hales, who laid the basis of that particular science, by experiments on living animals performed in the parsonage at Teddington? Do those whom, by a miracle of skilful surgery, you save from the misery of hyperthyroidism and restore to normal health realise that our knowledge of the thyroid gland and the possibility of this particular operation are due alike to the so-called vivisection of animals and men? Brain surgery, renal surgery, the surgery of the nerves, the spleen, the pancreas, the stomach, the ligature and suture of arteries, the use of artificial respiration, the treatment of anthrax, rabies, diphtheria, tetanus, and syphilis (to name only a few); the researches which led to all these were intimately bound up, from first to last, with experiments on, with the vivisection of animals, as well as men. This is a matter—as Foster said about Bernard—of plain historical fact, which those who wish may verify. No manner of abuse or misinterpretation will get over a plain historical fact. Is there a fool so great, or a criminal so wicked, that he would be willing now to *cause* the suffering to men and women which these advances in medical and surgical knowledge have already saved—and will save in the next 50 million years—in order to *prevent* the suffering to animals, such as it was, by which, once and for all, they were achieved?

In 1889 Mering and Minkowski found that complete removal of the pancreas in animals is followed by severe and fatal diabetes, and a long series of experiments led to the conviction that some chemical substance, prepared by certain patches of cells, the so-called islets of Langerhans, existing in that organ are essential to the normal utilisation of sugar by the body. So certain did this seem that—although all attempts to isolate it had failed—the name "insulin" was given to this hypothetical substance by de Meyer, in 1909, and independently by Schafer, in 1916. I need not tell you how the Toronto workers in 1922—only seven years ago—succeeded in isolating this substance, and how effective it has proved in the treatment of human diabetes. Those of us with friends and relations who are maintained in practically normal health by the daily administration of insulin, and who—in all human certainty—would die in a few months were the supply of insulin prevented, can appreciate what experiments on animals have done. Not only did the discovery of insulin rest absolutely upon experiments on dogs, rabbits, and other animals, but even its supply cannot be maintained at present, until scientific knowledge of its nature is advanced much further, without continual experiments on mice and rabbits, for its standardisation. This again is plain historical fact. There are people who assert, and affect to believe, that insulin has no effect on diabetes, or that, in fact, it does harm; they base their assertion on the crude handling of statistics. There are still people who believe that the earth is flat, and that spirits can make images on photographic plates. Have those who protest against insulin ever seen a patient, sick unto death in diabetic coma, pulled as by a miracle out of his sickness and restored to health? Would they dare to condemn to death a healthy happy man, in active work, a man such as many of us know, but a complete diabetic, by refusing him his daily dose of insulin because it has to be tested and standardised on rabbits or mice? The question really needs no answer; ultimately these are humane people, though they have bees in their bonnets.

It is only three years since the experiments of Whipple on the regeneration of blood corpuscles by dogs, bled and then fed on liver, led to the discovery that pernicious anæmia can be averted, if not cured, by feeding human patients with the same substance, or by treating them with liver extract. It is healthy, I know, to have a certain mistrust of "experts," but it is healthier still to have a mistrust of fools. Those who are qualified to judge, and have seen the evidence, are convinced of the efficacy of this treatment; they have no shadow of doubt about it, and it is plain historical fact again that it was led to by experiments on animals. Unfortunate, maybe, but true! Yet a medical man I once met, a valued member of an antivivisectionist society, asserted in my hearing that the liver treatment of pernicious anæmia is a delusion, since in fact there is no such disease at all; according to him it is really cancer of the bone-marrow—whatever that means (and he himself has a cure for cancer). Whose opinion should the public accept in this matter, which after all is not altogether unimportant since it involves quite a number of human lives?

We hear a great deal in these days about vitamins: the public enjoys the word, especially in America. I once had the privilege of sitting at dinner between two distinguished members of the advertising profession. One, I believe, was an arch bill-poster, the other I found later was concerned with the advertisement of patent foods. Neither knew who I was. The first began: "When I sit down next to a stranger I generally open the conversation by asking him, 'Do you know my distinguished cousin?'"—naming one of the greatest of living investigators. I did, and conversation progressed favourably, finally leading to vitamins. When I turned to my second neighbour I told him how conversation had opened on my other side, and how, of course, it had turned to vitamins. He replied that vitamins were the curse of his existence, that he wished they had never been discovered, that their discoverer was a criminal and ought to be locked up, and so on. He seemed in other respects a reasonable and healthy man, so I made further inquiries. It appeared that in every patent food vitamins have to be present—at any rate in the advertisement—and it gives him sleepless nights wondering how the word (not necessarily the substance) can be introduced. It is true, alas, that any new knowledge can be abased and exploited for commercial purposes, yet it remains a fact that many children and many adults in Great Britain *are* suffering from vitamin lack. Walk through the poor streets of many a great city—I will not say Manchester—at an hour when the children are not in school, and see how many you can spot who are suffering from obvious rickets. Now rickets can be cured—cod-liver oil or radiated ergosterol will cure it—at infinitesimal expense compared with the end to be gained. There is no excuse for rickets any more in a civilised community.

Other deficiency diseases are known—beri-beri, scurvy, &c.—but apart from definite disease, it is probable that many defects or weaknesses, not amounting to definite disease, are due to vitamin lack. We still do not know what most of these substances are, but a means of testing and controlling their activity is available in the feeding of animals. The discovery of vitamins was made by experiments on animals—though I admit that scurvy was discovered inadvertently, and a cure for it invented, by experiments on sailors. My friend, Prof. Elliott, once said to me that to Hopkins, for his work on nutrition and accessory food factors, medicine would owe more than to anyone since Pasteur. I at any rate can testify that Gowland Hopkins's researches involved experiments on animals—did I not work for several years in a coal-cellar at Cambridge, in the company of several hundred of his rats? I never saw him maltreat them—in fact, I have good reason to believe him to be the most kind-hearted of men—but this is "vivisection," to give it its legal title, and Hopkins's discoveries were made by "vivisection" in a coal-cellar. I am happy to have lived among the rats of such a "vivisector," and to have seen such a discovery emerge.

These matters are not unimportant. Human lives and human happiness are involved. Look up the history, recent or remote, of medical knowledge and treatment, explore the story of any medical discovery, and you will find experiments on men and experiments on animals inseparately mingled. It cannot, and it should not, be otherwise. *Anti-vivisection, in fact, is anti-scientific medicine;* and those who work in laboratories need a fearless recognition of the fact by those who work on patients. Your rewards, social and financial, are not usually less than theirs; it is you who have the ears of our rulers, whether in cottage or in mansion; they remain, to the public, obscure and somewhat mysterious people; it is you, in fact, and not they, who can stop, if anyone can, the crime of hindering or preventing medical progress by means of scientific experiment. The object of our opponents is frankly to put an end to medical research, in so far as animals are used, instead of men, for experiment. They say so openly. You reply that this is inconceivable. It is not inconceivable; it might very well happen. There are States in America where even the teaching of evolution is forbidden. Do not let England become the laughing stock of the world, like Tennessee!

THE PHYSIOLOGY OF SENSATION.

But enough of these unpleasant and futile controversial matters; let us turn for a moment to something of more interest. You have probably all wondered how it is that some things provoke you more than others, how you recognise things as hotter, colder, heavier, lighter, darker, more or less painful. The fact that you can distinguish pain from cold, or light from sound, is simple to explain—each has a specific kind of receptor, each sends in its messages to the nervous system along a different line. All the evidence, however, as garnered from innumerable experiments upon the nerves of frogs, tends to show that a nerve-fibre transmits its messages in an *all or none* way. Nervous activity consists of discontinuous waves, just as the pressure of a gas is due ultimately to bombardment by its separate particles. Now these waves cannot be varied in degree by varying the stimulus—a stronger stimulus does not produce a greater wave in the nerve, provided it produces one at all. How do we recognise a stronger stimulus, as we certainly do? We have indeed the finest appreciation of changes in our environment and in ourselves. The physiology of sensation, and of reflex and voluntary muscular response, together with our theories of the pathology of the nervous system, depend vitally upon an answer to the question—how are we aware of variations of intensity in a stimulus applied to a sensory end-organ?—and until a very few years ago no response was forthcoming. All our philosophy of the sensory relations of the human body to its environment depends upon the answer.

The physiology of the frog's nerve, most carefully and fully studied, seemed inadequate to explain this most obvious characteristic of the human nervous system. What an opportunity for scorn for those who expect research to be instantly followed by practical application! And yet, lying in this mass of exact data obtained on the isolated nerve of the frog, and on the generalisation built upon it, lay the means, as soon as the modern amplifying valve was applied to the action current, to open up a new field of physiology of great practical importance and of intense theoretical interest.

The nerve impulse had long been known to be accompanied by an electric change in the fibre in which it travels; this impulse lasts for approximately a thousandth of a second at any spot; it is of the order of size of a few milli-volts, but in a fibre embedded in a nerve trunk it is largely short-circuited, and the external effect to be recorded is very small indeed. Without amplification it is difficult enough to record a single wave in a whole nerve trunk with any accuracy, to record it in a single fibre is utterly beyond the reach of any available instrument. With the aid, however, of the tools which wireless engineers have provided, single nerve waves in single nerve-fibres can be amplified and recorded, and a whole new world of hurrying, scurrying activity is opened up to analysis.

The opening up of this new world is chiefly the work of Prof. Adrian and his pupils, and the answer to our question is at once apparent. The sensory end-organ records a *greater strength of stimulus by a greater frequency* of response. A heavier pressure on the skin sets up a greater number of nerve messages per second in the fibres running into the nervous system; a brighter light, a greater tension in a muscle, a hotter body, a stronger pinch or prick, are registered by a greater frequency of the impulses evoked by it. The experiments, conducted with splendid simplicity and skill, have left no doubt of the quantitative nature of sensory response. Not only can the separate waves in an afferent nerve-fibre be registered photographically, but they can even be transformed into sound and heard in a loud speaker. The physiology of sensation has taken a new jump forward, and nobody with a particle of scientific imagination can doubt that this new knowledge will have important bearings upon the pathology of nerve affections.

This work, however, has developed not only on the afferent or sensory, but also on the efferent or motor side of the nervous system. For a quarter of a century it has been believed that the only way in which the strength of a muscular response can be graduated is by a graduation of the *number* of muscle-fibres involved in it. All skilled movements, all fine work, the economy and precision which are rightly so much esteemed in the trained performer, which are lost in various disorders of the nervous system, all depend upon this precise grading of muscular effort. It seems now from Adrian's work that variation of the number of fibres involved in a muscular response is only the *coarse* adjustment; the fine adjustment is due to a graduation of the frequency with which the muscle-fibres are excited by their nerves. Here, again, in its bearings upon our theory of the working of the nervous system, we have a very fundamental fact. Such facts have been established by experiments on frogs, eels, rabbits, and cats—by "vivisection," that is to say, to give it its official title—though I am sure that no pain, worthy of the name, has been caused by them. They have been confirmed by experiments on men. At a meeting of the Physiological Society, Prof. Bronk, a collaborator of Prof. Adrian, had a fine electrode thrust into an arm muscle, and the resulting action currents were led off to an amplifying system and thence to a loud speaker. As he varied the force exerted by his muscle, the pitch of the sound emitted by the loud speaker waxed and waned; at first a rattle like a machine gun, and finally a musical note; one *heard* a single human muscle-fibre varying the strength of its contraction. No doubt the result *might* have been attained by a superhuman intelligence, without preliminary experiments on animals; it is a matter, however, of simple historical fact that it was not so attained, but that experiments on frogs and tortoises and eels, on dogs and cats and rabbits, were the *actual* path by which the result was reached. If anyone dares to assert that it is unimportant, the history of all scientific thought is against him. Indeed, if the understanding of anything at all in man's universe is important—which, of course, some people deny—it is of his own central nervous system.

THE CENTRAL NERVOUS SYSTEM.

Let me illustrate the matter further by a recent experience of my own. It is known that the extremely complex functions of the central nervous system depend upon an adequate supply of oxygen, that without oxygen they rapidly fail. It is known that central nervous activity is readily modified by fatigue. Now in trying to discover the fundamental nature of the activity of the nervous system we need something simple to work with; the central organ itself is so utterly out of reach of direct experiment, so hopelessly changed by isolation or interference, that we can do little but fire messages in, in various ways, and observe what comes out again. The study of the spinal cord and brain has become, in fact, the study of reflexes, whether automatic or conditioned, a study which in the skilful hands of Sherrington, Magnus, Pavlov, and many others, has opened new vistas of research and knowledge and promised—or indeed begun to provide—a rich harvest to the neurologist. The magnitude of their achievement I should be the last to under-estimate, but they would be the first themselves to recognise that their methods alone cannot solve the whole problem. What are the individual cells and fibres doing during activity? What are the physico-chemical changes involved in excitation, inhibition, and facilitation in the central organ? What *is* the central excitatory state revealed by Sherrington's experiments? Can we give some picture of the central nervous system based upon the elementary properties of the isolated nerve? A very difficult problem, which many people have tried and are trying to solve.

Let us consider an analogy. For centuries the movements and properties of the heavenly bodies have been studied. Astronomical discovery is perhaps the noblest monument to the human intellect. To-day, however, the flood of light which is being poured afresh upon the dimensions and time-relations, the history and evolution of the universe has resulted, not chiefly from astronomical observation as such, but from the labours of physicists in their studies of radio-activity, of spectra, and of the conduction of electricity through gases, and of mathematicians in their theories of the interchanges of radiation and matter. In 1929 the picture which science gives us of the universe is based upon the properties of atoms, electrons, energy, and radiation. So it must be with the central nervous system. In the solution a necessary step is to learn in greater detail the properties of the central nervous cells and of the fibres which project from them; we need to know them not only by their works at a distance, but by near and personal acquaintance. Keith Lucas made a first attempt to explain the fundamental characteristics of the central nervous system on the basis of those of the medullated nerve-fibre of the frog, an experimental object whose clear-cut functions we can investigate methodically in the laboratory by rigorous physical methods. Lucas's attempt has not been wholly successful; although patches of light have been thrown upon central nervous function by work upon the isolated medullated nerve of the frog, there is still much that remains obscure.

It may be that a further little step, in this type of analysis, is possible. It happened by good fortune some three years ago, at the Marine Biological Laboratory at Plymouth, that I examined the limb nerves of Maia, the spider crab. Other people, of course, have done this before, but they did not chance to have a galvanometer at hand. The activity of this tissue can readily be measured by recording its electric response to stimulation. To our astonishment the nerve was found to be obviously and highly fatiguable. It is almost impossible, as you know, to fatigue a medullated nerve. Students make experiments to show that it cannot be done. The researches of my colleagues, Levin and Furusawa, have shown this non-medullated nerve of Maia to possess some most interesting properties—properties which one would like to see examined as the possible material for an analysis of the central nervous system. The nerve can be fatigued, almost to complete exhaustion, by stimulation for a few minutes. Fatigue at the point of stimulation is greater than at a distance from it. In the presence of oxygen it recovers; in the absence of oxygen it does not. At 10° C., 25 minutes are required for complete recovery, from six seconds only of stimulation. Only 2 per cent. of the energy involved in activity is liberated during the passage of the impulses produced by excitation, nearly 98 per cent. in the succeeding 25 minutes of recovery. The normal resting state of the nerve is accompanied by an electrical potential difference across its surface. The potential difference is diminished or abolished by stimulation or by oxygen-want; here is an obvious and lasting effect of activity, which was not known at all in medullated nerve. In the presence of oxygen the potential difference is slowly restored, just as though it were due to a little accumulator which has to be recharged by a dynamo when it is run down. The energy used is many times as great as in the case of the medullated nerves previously examined. Hence perhaps the rapid onset of fatigue. There is evidence that the maximum frequency at which the nerve transmits its impulses rapidly decreases as activity continues.

Now the central nervous system consists largely of grey matter—that is, of nerve cells and of non-medullated nerve processes; only to a minor degree can its properties depend upon its medullated fibres. In the fatiguability, in the large amount of energy used, in the dependence on oxygen, in the varying degree of electric polarisation of its surface, may we not see in the crab's non-medullated nerve, more faithfully reproduced, the properties of the central nervous cells, than in the simple medullated nerve of the frog?

I realise that I am only guessing. Investigation as yet has not had time to enable us to do more. I am showing you, so to speak, Bernard's process of *feeling* at work. Nothing may come of it after all; feeling is often wrong. Only future research will show whether the comparison will prove fruitful, and I do not claim that any particular problem has been solved. I give you the comparison merely to illustrate a very early stage in scientific procedure. If, however, the guess proves to be right, we have here an example taken straight, so to speak, from the factory, of the principle which Harvey's work so fully emphasised of the advantage of trying your experiments "on many and several sorts of creatures," on any living animal on which you can lay your hands. The most unexpected creature in the world—even the spider crab crawling about at 20 fathoms—may help you to solve a riddle which would prove quite insoluble so long as your only experimental animal is man.

EXPERIMENT THE ONLY WAY.

Is it indeed conceivable that we can find out about life without examining life? The whole history of human knowledge and progress tells us the danger and folly of scholasticism and unverified hypothesis, the advantage of unbiased experiment and observation. If you wish to find out about the stars you must observe the stars, you must experiment with the materials which you suspect the stars to contain, you must try to reproduce, and to experiment under, the conditions which obtain in the stars; you must study spectra, electrons, radiation, gravitation; you will not be content merely with pictures of the sky at night. If you want to solve the problems of flight you must experiment on flight; you will never solve them merely by examining dead birds or fossil birds, or even living birds in cages. If you want to understand the properties of matter you must make experiments with matter, and apply mathematical calculations to your results as necessary; it is not sufficient to read what the Greek philosophers said about matter. If you want to know how living things evolved you must examine the strata of the earth, in which you can find them in their various stages of evolution ready to look at. You must not be content with the first chapter of Genesis. If you want even to play tennis you must experiment in playing tennis—all the books in the world will teach you nothing without the practical experience. So, if you want to understand life and the problems involved in life, if you want to acquire the power which an understanding of living processes will bring you, you must observe living things, you must take them to pieces to see how they work, you must become familiar by long experience with the way they behave.

Living processes, as Bernard upheld, are subject to the same determinism as the phenomena of the inorganic world. Cause and effect are related in the same way. There are no spooks, no spirits, no magic, no supernatural agency, no lack of causal relationship to hinder us from applying the same kind of exact quantitative experimental analysis as men are accustomed to apply to the facts of physics, chemistry, engineering, or astronomy. The only difference is that the problems of physiology, taken in its widest sense, are far more difficult and complex that those of the so-called exact sciences. The problems of biology require greater and not less experimental skill, more patience and not less, more time to unravel, more judgment and more understanding for their solution. Biology is *not* a soft job, for people with second-best brains; though physicists and chemists sometimes affect to think so. There is no evidence, however, that its problems are not ultimately soluble. We may not solve, as the newspapers would say, the "mystery of the origin of Life"; any more than astronomers can tell us how the universe of matter, energy, and radiation came into being in the beginning. Probably there *was* no origin and there *was* no beginning; at least there is no evidence at all on the subject. The real difficulties in biology are great, but they are experimental difficulties, not philosophical ones. If we wish to understand life we must experiment with it, not talk about it. Our experimentation, of course, must be led to by hypothesis, for random experimenting is as useless, as dangerous, as unverifiable hypothesis; but when once we have appealed to Nature to judge between our theories, we must accept her decision, without bias of hypothesis, or philosophy, or religion. We must trust absolutely to experience, guided by reason. *We must admit no challenge to the arbitration of experiment, except better and better and still better experiment.* The field of biology is vast, much of it is still quite unexplored, but we have a few landmarks to guide us. The fact of evolution is certain, the fact of determinism, the fact that the laws of the inorganic world apply in biology with the same precision as elsewhere. The field is not ripe yet for much more theory—exact quantitative experiment on living creatures and tissues is the present need, and will remain so for many years to come.

How, then, shall we proceed? By experiments on man? Surely, for man is the only experimental animal who will coöperate fully with the experimenter, and most important results have been obtained in recent years by controlled experiments on man. Besides, the habit of experimenting on man, on themselves and their friends, is a valuable lesson to learn for all those whose lives are to be devoted later to medicine; and no less important should it prove in connexion with the scientific study of industrial and social welfare. Let us, however, insist and continue to insist that human physiology and medicine are branches of biology as a whole. Man has a kinship, through evolution, with all the plants of the earth, the beasts of the field, the birds of the air, the creatures of the sea. Fifty years ago this conclusion was opposed by all the resources of sentiment and of organised religion. Even to-day there is widespread objection among the uneducated to the teaching of evolution, but none on the part of those who have studied the evidence. We *are* akin to the other creatures, and a frank acknowledgment of the fact need not, in fact does not, diminish our appreciation of the nobility of human nature or of the sanctity of human life. One objection to the use of animals in experimental medicine is undoubtedly the same old anti-evolutionary prejudice. To-day, however, the conclusion cannot seriously be contested, Bernard is admitted to be right, medicine and human physiology *are* branches of experimental biology. We must make them so in fact as well as in theory, in hospital and laboratory as well as in lecture room.

Let us advance, therefore, by experiment, hopefully and without fear. Harvey, by his experiments "using daily more search and diligence, by often looking into many and several sorts of creatures," did finally "hit the nail on the head" and so laid the basis of modern scientific medicine. To-day there are unlimited opportunities for experimental biologists, adequately schooled and disciplined in hard reasoning and exact methods, in its border sciences. From frogs to elephants upwards, from frogs to filtrable viruses downwards we may take our choice, according to the demands of the experiment; and the end of it is man. Puny, fearful, unreasonable, selfish he may sometimes be; yet possessing always elements of nobility, courage, kindness, and devotion such as no other animals possess, which make him, as was said 1900 years ago, "of more value than many sparrows." On his behalf, for his health, his happiness and his wisdom, for his freedom from suffering, superstition, and ignorance, experimental biology and experimental medicine should be ready to sacrifice, if needs be, many sparrows and many frogs.

TREATMENT OF CHOREA BY NIRVANOL.

BY F. JOHN POYNTON, M.D., F.R.C.P. LOND.,
PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL; SENIOR PHYSICIAN, HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET;
AND
BERNARD SCHLESINGER, M.B. CAMB., M.R.C.P. LOND.,
PHYSICIAN TO THE CHILDREN'S DEPARTMENT, ROYAL NORTHERN HOSPITAL; PHYSICIAN TO OUT-PATIENTS, HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET.

A NEW method of treating chorea with a preparation called nirvanol has recently had a fairly wide trial in Germany. In most clinics where the method has been used it has met with such constant success that it continues to be employed in severe and obstinate cases. Up to the present, knowledge of this form of therapy has failed to reach the shores of England or America, and we have been unable to find any reference to nirvanol in the literature of either of these countries.

During the last few months we have used the method in six cases of chorea, and have been sufficiently impressed with its favourable results to think it worth while to bring this new form of treatment to the notice of the English medical profession, so that it may receive more general trial in this country.

Nirvanol is composed of γγ-phenylethylhydantoin, and has the following formula:—

It is formed by the combination of urea and glycol, and was originally used as a hypnotic for sleeplessness and as a sedative in epilepsy and various types of psychosis. In chorea, relatively smaller doses are used, and successful results are not due to any hypnotic effect, but to a specific reaction which occurs after several days' oral administration. This reaction, on which the whole treatment depends, is akin to serum disease, or a mild anaphylactic shock, and is so distinct that it has been named nirvanol disease.

Method of Treatment.

The drug is administered by the mouth in daily doses of 0·3 g. for a child of 9 to 14 years of age. In most cases 8 to 14 days after beginning the treatment a well marked morbilliform rash appears usually accompanied by pyrexia. The drug is stopped directly this reaction occurs. The rash is at first composed of tiny red macules which, in the course of a day or so, enlarge and become slightly raised. The distribution varies, but usually the eruption is first noticed on the chest, abdomen, and elbows. From here it spreads to other parts of the limbs, the extremities being particularly affected, and spots are nearly always visible on the dorsum and soles of the feet, and sometimes on the palms of the hands. The back may be involved, but the face generally escapes. After about four or five days the rash gradually disappears, hardly having reached a definitely papular stage, and rarely becoming confluent except on the elbows. In our cases the rash always had this morbilliform character, but other observers have noted urticarial and scarlatiniform eruptions. There are few subjective symptoms, but conjunctivitis, pharyngitis, cervical adenitis, and slight œdema of the eyelids and face are apt to occur. Vomiting is uncommon, but there may be slight headache and drowsiness. The nirvanol rash does not usually irritate and, accompanied by these other slight manifestations, is strikingly like rubella. Its tinge, however, is not the typical pink of this infection, and more closely resembles a mild attack of measles, although the absence of true Koplik's spots is a valuable differentiating sign. In fact, this peculiar rash is best described as falling between these two exanthemata, not quite resembling either in some of the most important details.

The continental writers state that the temperature may be considerable for several days, rising as high as 104° F. in some cases, but in our patients this high pyrexia did not occur, and two remained afebrile throughout, although the rash was well marked. In any case the reaction is over by the third to fifth day, and it has been noticed that the earlier it is evoked in the course of treatment, the more severe is the rash, and the longer the duration of the temperature (Leichtentritt, Lengsfeld, and Silberberg).[1] Just before the onset of the fever the choreic manifestations seem to be aggravated, but with the disappearance of the rash they improve with dramatic suddenness, and are generally completely arrested within a week or ten days. In certain cases the reaction is delayed until the 24th day, and in others a curious secondary reaction may arise, similar to the primary one, 17 to 39 days after starting treatment (Leichtentritt et al)[1]. This occurs as long as 12 days after the drug has been stopped, and may occasionally be very severe (Keller).[2] Heart lesions, present at the time, are apparently unaffected and certainly not made worse, but in the German reports, details of the cardiac condition in the cases treated are meagre. In one of our cases the chorea was complicated by early carditis with dilatation. We had the impression that this was favourably influenced, and the heart had certainly resumed its normal size with the arrest of the chorea, although an apical systolic murmur persisted. The treatment has not been long enough in practice for us to form any opinion as to the ultimate prognosis. One or two cases have been described in which a relapse occurred many months after the first successful nirvanol treatment. In these children, nirvanol arrested the chorea again without producing the typical reaction on the second occasion (Keller,[2] Huber).[3] A few successful cures have also been reported in cases treated for the first time, which have shown little or no reaction (Schmal).[4] But in both instances the effect of the drug on the blood-picture is generally well marked despite the absence of rash or fever.

The most constant change in the blood is a true eosinophilia, which reaches its maximum just before the appearance of the rash. In addition, during the administration of the drug there is generally a leucopenia with a decrease of the polymorphonuclear cells and, at the same time, a relative lymphocytosis and monocytosis. With the subsidence of the general reaction the blood-picture gradually resumes the normal. These changes were mostly present in five out of our six cases, and have been tabulated on the accompanying charts. Eosinophilia appears to be one of the prominent features of nirvanol disease and, as already indicated, may occasionally be the only evidence of a reaction.

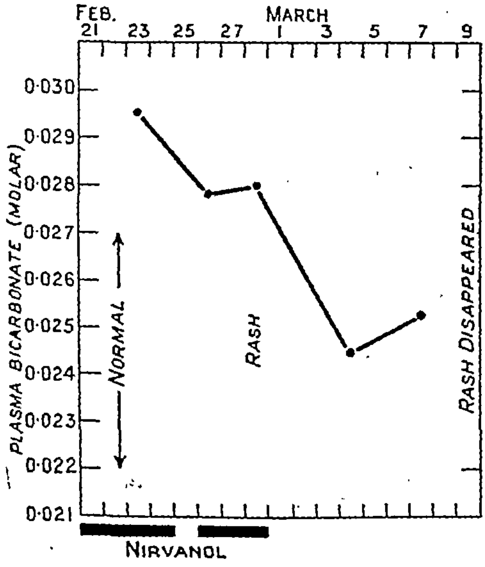
For the treatment to be successful one must aim at producing nirvanol disease, and with this in view a sufficiently large dose of the drug must be given, but there is as yet no means of regulating the severity of the reaction. It is wise never to exceed a daily dose of 0·3 g. of nirvanol. The drug must be stopped immediately the typical reaction (rash, fever, and so forth) appears, and if this has not occurred by the fourteenth day it is useless and even dangerous to proceed with the treatment (Huber).[4]

Pathology.

de Rudder[5] likens the reaction of nirvanol to that of serum disease, in which an alteration of the acid-base equilibrium of the blood has been found. He states that there is at first an alkalosis approaching a pro-anaphylactic tetany. The peripheral nerves share in the general stimulation, and this no doubt accounts for the temporary aggravation of the choreic movements. At the moment of the eruption the alkalosis is changed into an acidosis, and it is this sudden alteration presumably, which he claims, has such a marked effect on the central nervous system. Dr. W.W. Payne has investigated this point on two of our cases (Cases 3 and 4), and by measuring the blood plasma bicarbonate has been able definitely to confirm a tendency towards alkalosis during the administration of the drug, but was unable to establish any sudden swing over to acidosis. His estimations are tabulated in the Figs. 1 and 2. It will be noticed that, taking Blackfan and Bengt Hamilton's[6] figures, 0·022 to 0·027 molar as the normal, the plasma bicarbonate in Cases 3 and 4 was increased after a few days administration of the drug, but it never dropped below normal during the course of treatment. Thus there appears to be a tendency towards alkalosis, but not to an acidosis.

The usual effect of nirvanol appears to be absent in certain patients, and it is interesting to note that they are also resistant to the various sera, which in normal people would produce anaphylactic phenomena. This may possibly be taken as substantiating evidence that nirvanol disease and serum sickness are analogous. The exact manner in which the drug produces such a remarkable effect on chorea is not really known. It is certainly not due to a mere production of fever as, for instance, occurs in the malaria treatment of dementia paralytica, for the drug is just as efficacious when there has been no rise in temperature (see Cases 5 and 6). The eosinophilia can only be an integral part of the reaction, and seems hardly likely by itself to be the effective agent. If it were, other substances provoking eosinophilia might presumably have a beneficial action on chorea similar to nirvanol. We can hardly believe the explanation is that of protein shock.

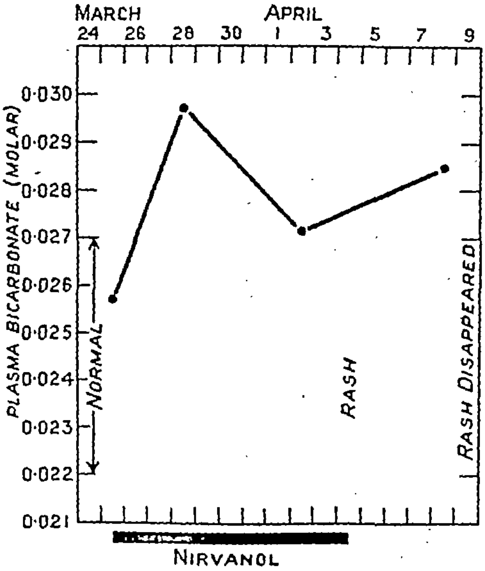
FIG. 1.



The blood-plasma bicarbonate estimation in Case 3.

Extensive animal experiments have been performed by Leichtentritt, Lengsfeld and Silberberg.[1] They produced shock in rabbits by injecting them intravenously with serum of patients previously treated with nirvanol, but there was no eosinophilia. Oral administration of the drug to these animals caused a marked leucopenia with relative lymphocytosis. When this was continued long enough the bone-marrow became seriously affected and an aleukæmia was produced, closely resembling that occurring in benzol or salvarsan poisoning, and after an excessive use of X rays and radium.

FIG. 2.



The blood-plasma bicarbonate estimation in Case 4.

Dangers.

Although the six cases we have treated ran a mild and favourable course, these experimental results serve as a warning that nirvanol is not a harmless drug, and that its exhibition, if not closely watched, is liable to be dangerous. It should never be given unless the doctor in charge is conversant with its action, and the patient must be under constant medical supervision. The possibility of a deleterious effect on the bone marrow must be kept in mind in the present stage of our knowledge of this treatment, and a watch kept on the leucocyte fall. Even with the most careful administration, alarming results have been reported on rare occasions. For example, Keller describes the following case. After a typical reaction occurring on the sixth day of nirvanol treatment, followed by a striking arrest of the choreic movements, the drug was stopped immediately and the patient appeared to be cured. Eleven days later, however, a severe secondary reaction set in with high fever, headache, and a second scarlatiniform rash, tonsillitis, gingivitis, stomatitis, nephritis, enlargement of the liver and spleen with jaundice, blood-stained diarrhœa, swelling of the face and œdematous ulceration of the upper lip. A protracted recovery eventually ensued, and was complicated by troublesome furunculosis. There was some reason to believe that the formidable secondary reaction in this case was brought on by accidental exposure to sunlight. This may have been a coincidence, but since another severe secondary reaction has been reported after giving artificial sunlight to a patient who had just finished his course of nirvanol, it appears wise to guard against such rays for two or three weeks after this form of therapy.

The rash may very occasionally extend to the bronchial mucous membrane as in measles, and give rise to broncho-pneumonia (Pilz).[7]

Results.

Good reports of nirvanol have come from various German clinics. Roeder[8] in Gottingen, Rietschel,[9] and Hester[10] in Wurzburg, Husler[11] in Munich, Matzdorff[12] in Breslau, Huber[2] and Schmal[4] in Berlin, Keller[3] in Karlsruhe, all subscribe to the effectiveness of the drug. Two other independent observers, however, Bendix[13] and Buttner, are not so enthusiastic, and find no advantage in nirvanol over any other form of treatment of chorea.

Judging from the following cases treated by this method, we have been impressed by the beneficial effect of the drug on chorea, and the disappearance of the movements has certainly seemed to us to be more rapid and complete with this form of treatment than with any we have employed hitherto.

CASE 1.—A girl, aged 11, had been suffering for three weeks from severe acute chorea, which had probably been precipitated by overworking for a musical scholarship. She had suffered from pains in the limbs six months previously.

March 28th, 1929: On admission, movements were incessant, and the child was very restless with speech affected; heart normal. April 3rd: Nirvanol started, 0·3 g. daily. 5th: Sore throat; restlessness increased. 6th: Slight headache; temperature 101·4°; tachycardia, 140. 7th: Temperature subsided; pulse-rate 100. 8th: Mild conjunctivitis; no change in chorea. 13th: Rash appeared first on both elbows; scattered papules on hands, wrists and soles of feet; nirvanol stopped. 15th: Rash more extensive and irritating. 16th: Rash still developing and confluent in certain areas. 17th: Rash fading; chorea improving. 20th: No chorea.

CASE 2.—A boy, aged 10 years, had been suffering from mild but persistent chorea for three months, which had not improved under treatment at home. There was no previous history of rheumatism.

Feb. 10th, 1929: On admission, mild chorea present; heart showed some enlargement to the left with systolic murmur at the apex; normal temperature. 10th to 28th: Rest in bed without drugs produced no improvement. March 1st: Nirvanol started, 0·3 g. daily. 6th: Slight puffiness of the eyelids; heart resumed a normal size, but systolic murmur persisted. 9th: Temperature 99·6°; no alteration in pulse-rate. 10th: Rash appeared, morbilliform in character; face flushed, macular rash all over the body, conjunctivitis, infected fauces and a few small white spots on the buccal mucosa; axillary glands palpable; sore throat, but no other symptoms; temperature 99·4°; nirvanol stopped. 11th: Temperature subsided. 12th: Rash faded; movements less. 21st: No chorea.

Feb. 15th, 1929: On admission there was moderate chorea with considerable hypotonia which showed no improvement with rest in bed; heart normal. 21st: Nirvanol started; 0·25 g. daily. 25th: Temperature 100°; nirvanol omitted for 24 hours. 26th: Nirvanol recommenced, 0·25 g. daily; temperature normal. 28th: Morbilliform rash; nirvanol stopped. March 13th: No chorea.

CASE 4.—A boy, aged 10, had had three mastoid operations, and following the last one, chorea had developed two weeks before readmission to hospital. At the same time there was a history of pains in the limbs.

Jan. 14th, 1929: On admission chorea was of moderate severity and movements were even present during sleep. No definite evidence of cardiac involvement. Treated with bromides and arsenic, but without improvement. 24th: Chorea still well marked. Feb. 12th: Movements not so evident. 25th: Relapse of chorea. March 4th: Bromides and arsenic stopped; tolysin treatment started. 11th: Chorea still present. 25th: Nirvanol started, 0·35 g. daily. April 1st: Temperature 99·8° for one day. 4th: Rash appeared first on the wrists, morbilliform in character; nirvanol stopped. 5th: Rash spreading. 9th: Rash disappeared; chorea absent. May 23rd: Report from convalescent home stating that there has been no return of symptoms.

CASE 5.—A girl, aged 13, had been suffering from chorea for two months. Five years previously she had had a similar attack lasting three months, which was treated in turn with chloretone, bromide and arsenic. The present attack dated from an influenzal infection, and was at first treated by rest in bed at home together with salicylates, but without improvement. Heart normal.

April 25th, 1929: On admission to hospital the chorea was moderate, and affected the tongue and the right side of the body more than the left. May 4th: No improvement from rest in bed and aspirin; nirvanol 0·3 g. daily started. 5th: Slight drowsiness. 6th: Slight increase in chorea; drowsy. 7th to 11th: No change. 13th: Rash appeared, starting on the elbows and spreading thence to the chest, abdomen, soles of the feet and palms of the hands; a few spots on the mucous membrane of the lower lip; nirvanol stopped. 14th: Rash more clearly defined; a few papular spots and erythematous patches most marked on the elbows, fading easily on pressure; slight enlargement of the occipital glands. 16th: Rash fading; movements less. 21st: Rash has disappeared. 22nd: No chorea; there was no appreciable alteration in temperature throughout the treatment.

May 2nd, 1929: On admission there were well-marked movements affecting the face, body and limbs, the left arm being very hypotonic; speech was bad; heart normal. 4th: Nirvanol, 0·15 g. 5th: Nirvanol, 0·45 g.; slight headache. 6th: Nirvanol, 0·3 g., which was then repeated daily; drowsy at times; no change in chorea. 7th to 12th: No change. 13th: Rash appeared; macules on elbows, chest, abdomen, forearms and palms of the hands; one red spot on mucous membrane of the lower lip; nirvanol stopped; no change in movements. 14th: Rash more marked, morbilliform in character over neck, face, and trunk; a few papules on dorsum of the feet. 16th: Rash fading; chorea improving. 18th: Rash has disappeared; great improvement of chorea during last three days; there was no appreciable alteration in temperature throughout the treatment.

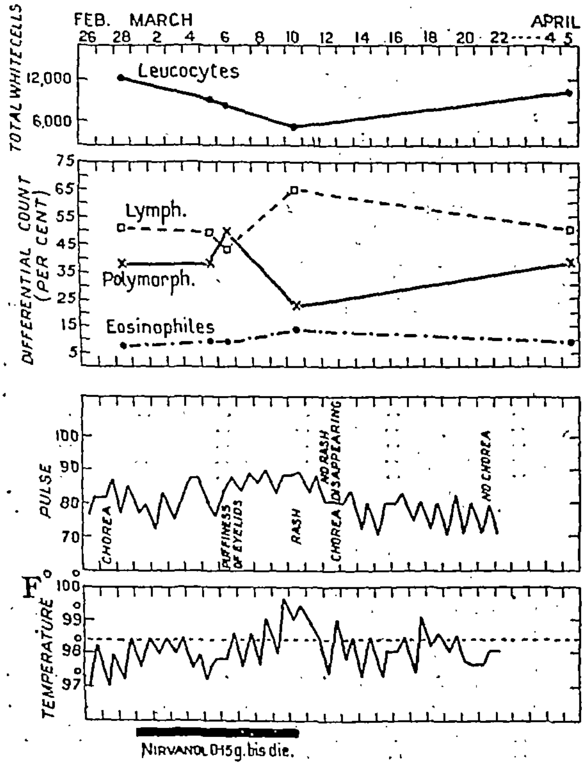
The effect of nirvanol on the blood was fairly constant in the first five cases, and followed pretty closely the changes referred to in the text. Cases 2 and 4 are such typical examples that they have been graphically represented (Figs. 3 and 4). There was no appreciable alteration in the blood count of the sixth case, and it is interesting to note that, unlike the others, this boy, although greatly improved, could not be counted completely cured.

Conclusion.

Other attempts have been made to treat chorea along similar lines. The method of Duzar in which adrenalin is injected intravenously, while at the same time alkalosis is produced by large doses of sodium bicarbonate by the mouth, has perhaps received the greatest attention, but it appears to be cumbersome and unreliable.

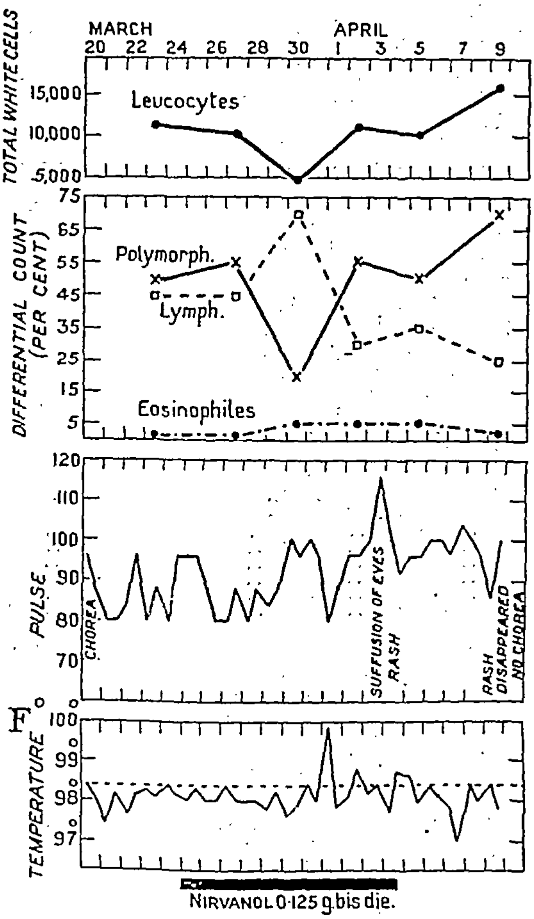
Judging from the many accounts from various independent sources, since Roeder's original communication in 1919, nirvanol certainly does seem to be a potent drug, which is effective in the treatment of chorea, and has the advantage of oral administration. Against this is the fact that there is a small element of risk in the treatment, and for this reason it may be considered unjustifiable to take such heroic measures to combat a self-curable disease. On the other hand it seems unwise to dismiss nirvanol summarily on this plea alone. We have all seen the severest cases of chorea recover with only the most trifling symptomatic treatment, but we have also seen these cases develop permanent heart disease before they are finally cured. It may be that the arrest of chorea before it has run its course may also prevent the rheumatic infection from reaching the heart. It is also possible that by treating a child with nirvanol during its first attack, relapses may be largely avoided. More prolonged investigations are necessary before these points can be decided. Should the ultimate prognosis of chorea after nirvanol prove more favourable than it is with our present modes of treatment, then the drug indeed would have been a valuable discovery. Finally, we might add that in two further cases, under our care, rheumatic nodules of long standing disappeared rapidly after a course of nirvanol.

FIG. 3.



Blood counts, temperature, and pulse-charts of Case 2.

FIG. 4.



Blood counts, temperature, and pulse-charts of Case 4.

We are greatly indebted to Dr. P. O. Ellison, Dr. Alan Moncrieff, and Dr. G. W. Goodhart for the blood counts of our cases, and for the interest they have taken in this new form of treatment.

ASTHMA AND HAY-FEVER.

By J. E. R. McDONAGH, F.R.C.S. Eng.

Asthma and hay-fever are mild forms of shock affecting the respiratory system, and their nature does not differ from that of shock occurring elsewhere in the body. Shock depends generally upon two factors: (1) a precipitation of colloid protein particles in the vessels of the organ involved, and (2) a loss to the organ of oxygenated blood. In the respiratory tract shock is caused by a precipitation of colloid protein particles in the lymphatic spaces and capillaries, and to a lesser extent in the narrowed arterioles and arteries. The particles become precipitated when they increase in size, absorb water, and undergo agglutination. This change is termed hydration, and is brought about by any agent which will lower their surface tension to a minimum, such as histamine, nicotine, urecoline, coniine, insulin, unprotected colloid, and aluminium or ferric hydroxide. The removal from the tissues of the corpuscular components of the blood causes an immediate reduction in the activity of the tissues. This results in a relaxation of the peribronchial muscular tissue, so that the bronchioles are not constricted. In opposition to current views, I maintain that constriction of the bronchioles does not occur in the most severe form of pulmonary shock, the important feature of the condition being the relaxation of the muscles. The vagus plays little or no part in the actual causation of asthma and hay-fever. Less severe hydration causes the corpuscular elements to collect in the branches of the pulmonary artery, where the cells and tissues are stimulated and deprived of oxygenated blood. The venous congestion attracts polymorphonuclear leucocytes, which break up the hydrated particles into smaller particles. This inflammation, though it relieves the condition of asthma, may lead to broncho-pneumonia or any kind of infection of the respiratory system. Palliative drugs disperse the symptoms by breaking up the protein particles into particles bearing an adequate negative charge. If an excessive number of the particles resulting from dispersion bear a diminished negative charge, thrombosis occurs, but usually most of the particles leave the colloid state to go into true solution. This change is termed dehydration, and the increased flow of blood in the vessels changes the dyspnœa to the inspiratory type.

The action of adrenalin on asthma is not to stimulate the sympathetic nervous system, but to disperse the hydrated particles, through its negatively charged aliphatic methyl group and its negatively charged phenolic hydroxyl group. It is harmful if used over a long period because of the interstitial changes which it brings about in the mesenchymatous tissue, which in the end cause hydration of the protein particles in the plasma as a cyclical change. Much better results, without these harmful effects, are obtained from strontium aspartate, calcium oleate, camphor, acetyl-choline, and choline, which are conductors; and oxygen, which is a dehydrator. Atropine, because of the large size of its nucleus, exerts an initial hydrator effect on the protein particles, and dehydration only occurs later by reason of its negatively charged active groups. It therefore aggravates certain cases of asthma. This property has escaped general recognition, doubtless because atropine is wrongly thought to have a direct action upon the vagus.

The Cause of the Attack.

Any hydrator may precipitate an attack of asthma and hay-fever, especially in persons whose protein particles have already been partly hydrated. The precipitating factor, the foreign protein, may increase the hypersensitiveness, but to remove it does not get rid of the primary cause of the hydration. This explains why cutaneous tests are valueless, and the removal of feathers and other sources of foreign protein from the surroundings only a palliative. An important hydrating factor is a combination of the sun's rays and muscular exercise; this is why hay-fever is most common in summer, and why asthma is so apt to occur in September. The prime cause of hydration is, however, inherited chronic intestinal intoxication, to which focal sepsis of all kinds is *secondary*. *The initial hydration or state of hypersensitiveness is caused by the entrance into the blood stream of poisonous products of digestion.* These are manufactured by mutation forms of the normal *Bacillus coli communis*, and consist of foodstuffs altered physically rather than chemically. The hydrated protein particles collect in the walls of the large intestine, to aggravate the condition first by stimulating and then by paralysing the nerve-endings of the vagus in Auerbach's plexus. This produces a hyper-activity, and later a hypo-activity, of the centre of the vagus in the brain, and finally of the cerebral cortex. Incoördination is produced, and intestinal stasis is aggravated, so that the result is a vicious circle. Hydration can be transmitted by both parents, and asthma and hay-fever are therefore symptoms of hereditary disease.

Treatment.

Asthma and hay-fever cannot be cured until inherited disease is eliminated. The treatment resolves itself into removing, as far as possible, the chronic intestinal intoxication, in coördinating the individual, and in correcting the abnormal chemico-physical state of the protein particles.

Removal of the chronic intestinal intoxication is best achieved by washing out the colon as far back as the ileocæcal valve by the syphon method, by having the bowels opened two or three times a day ever afterwards, by avoiding animal food as far as possible, and in particular butcher's meat, eggs, and milk in large quantities, and by immunising the patient against the pathogenic micro-organisms found in the excreta. *While the ascending colon and cæcum are being washed out, drugs may be incorporated in the fluid, as absorption readily takes place through this part of the large intestine.* The best aperients to use are taxol, and some preparation of liquid paraffin. The manner in which the food is cooked forms 50 per cent. of the problem of diet.

The actual treatment of an attack of asthma depends in the main upon whether the attacks recur at long or short intervals and upon whether they are taken at their inception or later. Patients who have continuous asthma and signs of interstitial pneumonia do best with iodine, thyroid, and ichthyol or thiol-amino-methyl-glyoxaline, prescribed internally, and with small and repeated doses of the carbon di-sulphide product of di-ethyl-amine (contramine) injected intramuscularly. Patients who get an attack now and again should *receive two intramuscular injections* either of sup. 36 (0·01 g.) or of B.N. 368 (benzoyl-para-amino-benzoyl-3-6-8-hydroxy-naphthylamine: 0·005–0·01 g.), on two successive days. This is the best treatment in cases of hay-fever, because both asthma and hay-fever are most frequently occasioned by the hydration undergone by certain protein particles in the plasma through the dehydration of other protein particles. Both the compounds function as conductors; they correct the dehydration and cause dispersion of the recently hydrated protein particles. Provided an attack of asthma is treated at its inception and a case of hay-fever at the beginning of the season, the attack may be cut short and the next warded off for months, in some cases for years, while hay fever can be checked for the season and one or more ensuing seasons. I have had several cases each *of asthma and hay-fever* where the timely use of sup. 36 or B.N. 368 checked the attack instantaneously and prevented its recurrence, while the treatment of the primary cause was being carried out. When the hydration is well advanced pure conductors are useless for causing dispersion, and only simple dehydrators and conductors with a dehydrator action can be employed. Dehydrators need to be used with caution, because the ultimate result of using too large or too many injections is itself hydration, the state responsible for the attack. Therefore I use dehydrators having the minimum hydrator effect and those which possess a conductor action as well. Choline and acetyl-choline are useful at first, but they usually fail when re-employed. Strontium aspartate in 0·01 g. doses, injected intramuscularly every day or every other day, is a most useful drug in the less severe attacks, and is to be preferred to adrenalin. In some of the more severe cases, even when combined with oxygen subcutaneously, the drug may fail to cause dispersion of the hydrated particles. In some cases no known drug is able to correct the abnormal chemico-physical changes, and the attack has to run its course until the hydrated protein particles undergo the cyclical change of dispersion. Peptone, advocated by Auld,[3] [4] acts by causing dispersion of the hydrated protein particles and, being a derivative of protein, its action is essentially homœopathic. It must be used with caution, because a reaction (hydration) causes a serious aggravation of the trouble. Peptone does not cure asthma and hay-fever and, although its initial use may check an attack, it often fails to act a second time. Heroin is the most efficacious hypnotic in asthma, because the two acetyl groups cause dispersion of the hydrated protein particles. The greatest caution is necessary, because of all the condensed nuclei of benzene its vehicle phenanthrene is the one which causes the maximum degree of protein hydration. These methods have proved successful in a large number of cases, the end-result varying chiefly with the stage to which the chronic hydration had progressed and with the condition of the patient.

Illustrative Cases.

CASE 1.—A boy, aged 7, had had asthma every night for six months. The attacks were aggravated by active exercise. The mother and father had been operated upon for appendicitis and the mother's brother is Case 4. The patient had cyclical vomiting *as an infant*, hay-fever every year, and nocturnal enuresis occasionally. The teeth were bad and the hands were covered with warts. The urine gave an intense reaction with the hydrochloride of di-methyl-para-amino-benzaldehyde. Blood examination was as follows:—

Suspension stability of the red blood corpuscles	0·1 c.cm.
Refractive index of the serum	1·3473
Percentage of blood-sugar	0·137 g.
Percentage of blood-urea	16 mg.

Ultra-microscopic picture: Many particles moving with many large and refractile giant particles, ringed particles, and giant particled clumps precipitated.

Bacteriological examination of the excreta: 10 per cent. atypical *Bacillus proteus hydrophilus.*

Treatment.—Patient was dieted, made to have the bowels open two to three times a day, was given a course of treacle enemas till colon was clear, and had injections of the fæcal vaccine in doses of 125,000. The patient recovered completely; two injections of sup. 36 (0·005 g.) stopped the asthma at once.

CASE 2.—A girl, aged 9, had suffered from asthma since birth. Maternal grandfather and grandmother died of cancer; father suffered from hay-fever and his mother and brother were chronic asthmatics. Patient had one brother and two sisters; the brother suffered from asthma and the sisters from urticaria and epilepsy respectively. Blood examination was as follows:—

Suspension stability of the red blood corpuscles	0·7 c.cm.
Refractive index of the serum	1·3489
Percentage of blood-sugar	0·112 g.
Percentage of blood-urea	41 mg.

Ultra-microscopic picture: Many particles moving with a fair number of giant particles, all of which had a halo around and were very refractile. The other particles moved very actively around the giant particles. There were some clumps and agglutinations precipitated.

Bacteriological examination of the excreta: 20 per cent. *Bacillus fæcalis alkaligenes.*

Treatment.—Patient was dieted, made to have the bowels open two to three times a day, was given a course of treacle enemas till colon was clean, and had injections of the fæcal vaccine in doses of 250,000. The patient recovered completely.

CASE 3.—A woman, aged 28, who used to suffer from asthma and chronic bronchitis as a child, sought advice for constant abdominal pain. The patient had had attacks of rheumatic fever and was supposed to have had typhoid fever and paratyphoid. She had suffered from seborrhœa and acne vulgaris, and had once been jaundiced. The patient was always depressed; she suffered severely from dysmenorrhœa, and was in every way a typical example of familial chronic intestinal intoxication. Blood examination was as follows:—

Suspension stability of the red blood corpuscles	0·3 c.cm.
Refractive index of the serum	1·3502
Percentage of blood-sugar	0·118 g.
Percentage of blood-urea	18 mg.

Ultra-microscopic picture: Fair number of particles moving, with some very refractile giant particles and ringed particles. There were many giant particles, clumps, and agglutinations precipitated, with some precipitated en masse.

Bacteriological examination of the excreta: 60 per cent. Morgan bacillus.

Treatment.—Patient was treated in the routine way and recovered completely. This case shows that in spite of the asthma and bronchitis disappearing other signs and symptoms, the result of protein hydration, presented themselves.

CASE 4.—A man, aged 33, had had asthma for 14 years; eating eggs and having anything to do with rabbits brought on an attack immediately and the smell of petrol frequently precipitated an attack. The patient was the uncle of Case 1. The patient suffered from chronic bronchitis as a child, had had two attacks of rheumatic fever, and had been afflicted with acne vulgaris for many years. The optic discs were mal-developed, the ears were prominent, the elbows were wide-angled and hyperextended, and the patient could not stand with his feet and knees together. All the molars had been stopped or removed; the tongue was furred and the patient had acro-asphyxia. The pulse was 80 and the blood pressures registered 105 and 70 mm. Hg respectively. An examination of the abdomen revealed tenderness in both hypochondria and both iliac fossæ. The urine gave an intense reaction with the hydrochloride of di-methyl-para-amino-benzaldehyde. Blood examination was as follows:—

Suspension stability of the red blood corpuscles	1·2 c.cm.
Refractive index of the serum	1·3487
Percentage of blood-sugar	0·082 g.
Percentage of blood-urea	39 mg.

Ultra-microscopic picture: Few particles moving with some giant particles and ringed particles. There were more particles precipitated as giant particles, ringed particles, and clumps. The precipitation amounted almost to precipitation en masse.

Bacteriological examination of the excreta: 20 per cent. *Bacillus proteus valerici.*

Treatment.—Butcher's meat, eggs, and milk were excluded from the diet; the colon was washed out; the attack which the patient had at the time of examination was checked with two injections of B.N. 308 (0·005 g.), and later four injections of the fæcal vaccine were prescribed in two courses of two in a half and one million respectively. The patient had had a course of peptone injections without benefit. He recovered completely and was able to resume his occupation as a motor mechanic.

Summary.

Asthma and hay-fever are symptoms of inherited disease caused by the precipitation of hydrated protein particles and by the lack of oxygenated blood in the respiratory tract. The chief signs and symptoms of inherited disease are mal-coördination and a chronic intestinal intoxication. Asthma and hay-fever can usually be prevented by correcting the mal-coördination and removing the chronic intestinal intoxication.

Asthma and hay-fever are not diseases. Asthma is not caused by a stimulation of the vagus occasioning a constriction of the bronchioles. When adrenalin palliates an attack it does so by causing the hydrated protein particles to disperse, not by stimulating the sympathetic nervous system.

Asthma and hay-fever can usually be overcome with drugs able to cause dispersion of the hydrated protein particles. These measures are really no more than palliative, and a "cure" can result only in the prevention of inherited disease.

ANTIDYSENTERY BACTERIOPHAGE IN THE TREATMENT OF BACILLARY DYSENTERY.

A RECORD OF SIXTY-SIX CASES TREATED, WITH INFERENCES.

By ARTHUR COMPTON, D.Sc., M.D. N.U.I.,
DIRECTOR, MUNICIPAL PUBLIC HEALTH LABORATORIES, ALEXANDRIA, EGYPT.

DYSENTERY is one of the three most fatal infectious diseases of the urban population of Egypt. The official figures for Alexandria for 1927 and 1928 show on a mean population of 579,485 a death-rate from tuberculosis of 1, from diphtheria of 0·3, and from dysentery of 0·2 per thousand; but for the five years 1924–28, in an average population of 560,218, the total deaths registered from these three diseases were: tuberculosis 8532, dysentery 844, and diphtheria 572. This gives over the longer period a mean yearly dysentery death-rate of 0·3 per thousand. Of these deaths the majority must be put down to bacillary dysentery; first, because, judging by the laboratory diagnosis of specimens, this is far the more prevalent form of the disease,* and secondly because more specific and satisfactory therapeutic measures (emetine, yatren) have hitherto been available for the treatment of amœbic cases.

When I took up my duties in Alexandria in 1926 I found that the serum treatment of bacillary dysentery had largely fallen into disuse as inefficacious and that many cases of bacillary dysentery were, in my opinion, being erroneously diagnosed and treated as amœbic. This meant that before 1927 many, perhaps most, bacillary dysentery cases in the district, received no specific treatment whatever. Can the impressive fall in death-rate for the years 1927 and 1928 be accounted for by the institution of a relative amount of specific treatment, or must it be passed over as something incalculable, although it represents an economy of close upon 100 lives per year? I believe that it is related to the use during those two years of antidysentery bacteriophage for the treatment of a certain proportion of the bacillary dysentery cases in the district. Towards the middle of 1927 I began preparing and distributing gratuitously antidysentery bacteriophage for therapeutic use to doctors in the city who were willing to coöperate in an endeavour to obtain information on the value of this treatment. The distribution was limited to cases which had been diagnosed cytologically in these laboratories as bacillary dysentery. Opinion then was, and to a large extent still is, divided as to the therapeutic merits of bacteriophage.

d'Herelle (1926[1]), guided by the bacteriolytic property of bacteriophage which he had established in vitro, inaugurated this treatment in 1921 on five cases of Shiga dysentery. The results were excellent: the bloody stools ceased within 24 hours in each case and the patients entered upon immediate convalescence. Enthusiasm, however, shortly afterwards waned. Otto and Munter (1921) in Germany, Davidson (1923) in America, and Fletcher and Kanagarayer (1923) in the Malay States recorded essentially negative results. Against this Da Costa Cruz (1924) in Rio de Janeiro, after an initial series of poor results, finally established uniform success, and thereby confirmed d'Herelle's original observations. This was the situation when the present investigation was begun and throughout its progress.

Phage Employed: Its Preparation and Distribution.

The therapeutic phage distributed was of multiple origin and polyvalent quality. It consisted initially of four phage-strains: one passed to me by d'Herelle and three others isolated by me in Egypt. The mixture was put up against 16-hour broth-cultures of some 12 *local* strains of dysentery bacilli: two Shiga, three Flexner, six Hiss (including one Sonne), and one Gay. Hiss type constitute the predominating organism in the Alexandria region. Complete lysis of the cultures occurred after a few hours in the incubator at 37° C. After 24 hours' incubation the lysates were mixed and filtered through a filter impregnated with infusorial earth, and later through a L3 Chamberland filter. The filtrate constituted the therapeutic phage. It was transferred to sterile ampoules in quantities of approximately 2 c.cm. Three ampoules were, as a rule, distributed to each patient undergoing treatment, with a circular instructing the patient on the use of the phage and a questionaire to the doctor, to be filled up and returned to the laboratory later. Nearly 200 cases received treatment, about 50 in 1927 and 150 in 1928, and circulars were returned from 92 cases. Of these, only 66 were full enough to use.

The remaining cases from whom no returns were received have, I consider, to be reckoned for the most part as "cures," since had they been "failures" they would have reported again at the consulting-rooms of their medical attendants. As they were mostly poor and left no addresses, they could not be satisfactorily followed up. But providing them with phage probably meant to a certain extent the dissemination of antidysentery phage in their surroundings, a factor to which d'Herelle has attached some importance, since he holds that "immunity by phage, like the disease itself, is infectious."

Clinical Results.

For simplicity of interpretation and ease of reference, the results arrived at are classified in a general way, as follows:—

+ + + —Very good—Stools reduced to 2–3 per day by the 2nd day (counting the initial day as 0), in conjunction with improvement in the general condition of the patient.
+ + —Good—{Stools reduced to 3–4 per day by the 3rd day, or Stools reduced to 3 per day by the 4th day} with improved general condition.
+ —Moderately good—Stools reduced to 4–5 per day by 5th day.
(+)—Partial failure—Little or no change in the number of stools or in the general condition within 4 days, but ultimate recovery.
——Failure—Death, or no change within 1 week of commencing treatment.

When anti-serum treatment was first being tried two factors were mainly relied upon as criteria of cure: (1) lowering of mortality, and (2) diminution in the duration of the disease, compared with the recognised slowness of cure when drug treatment only was available. Thus, Kolle and Hetsch (1918) record that the nervous symptoms diminished, the patient's strength returned, the colic and tenesmus ceased, while blood and mucus gradually disappeared from the stools, which in 2–5 days regained their normal composition. In many cases, however, progress was not so rapid. Dopter and Saquepée (1921) observe that the number of stools became lowered to 8–10 in 24 hours, to remain stationary at this level for many days. All authors have noted that when serum-therapy was instituted late it seemed to have no effect. This applies to a certain extent also to phage-therapy, as a badly eroded intestine naturally cannot return all of a sudden to its status quo ante.

The result of phage was "very good" in 35 of our 66 cases, "good" in 10, "moderately good" in 6, a "partial failure" in 5, and a "failure" in 10. Two cases, however, had been ill a fortnight and were practically dying at the moment of the phage intervention. This was presumably true also in a third fatal case in which the date of onset was unknown. One patient was ill about two months before the phage was given, and naturally an immediate cure was out of the question, in view of the intestinal lesions present. Eliminating these four cases, the failures are reduced to six. On the severest possible analysis, grouping these 6 "failures," the 5 "partial failures," and the 6 "moderately good" results together as failures, we have in all 17 failures and 45 successes on a total of 62 cases. This represents a minimum percentage success for the treatment of 72·6. Of the failures, three had been ill for a week—maybe more—before the phage treatment was begun; two of them were children less than one year old. Both early intervention and the age of the patient play an important rôle in the success of the treatment.

---

* Our statistics indicate that 80–90 per cent. of all dysenteries in Alexandria are bacillary. The records of the Public Health Laboratories, Cairo, indicate a similar state of affairs. (See Perry and Bensted, 1925.)

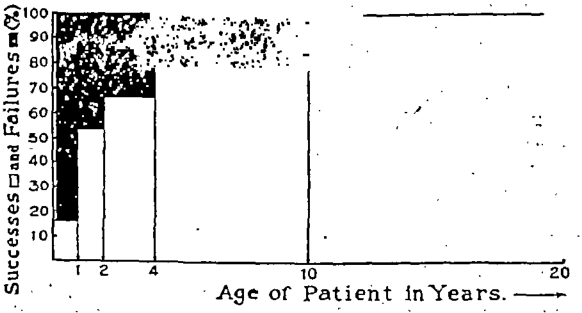
In five cases anti-serum treatment was employed in addition—an unintentional experiment, since it was no part of my idea that serum should be used—it was administered independently by the treating physician. Three of these figure as failures and two as successes. Of the three failures, one had the serum before and two after the phage, while the two successes had the anti-serum before the phage. If any conclusion is justified by these cases it is, I think, that there is no contra-indication to phage when the patient has already had serum. The two successes are interpreted rightly or wrongly, as solely due to the phage. This interpretation is, I think, justified by the clinical notes. Moreover, all authorities are agreed that for antidysentery serum to be of any use it must be given in large doses, and not in the 10 c.cm. doses generally used here.

It is well known that certain cases of bacillary dysentery *do* well on saline treatment alone, or even on emetine, but this does not invalidate the successes attributed to phage, because it is a well-established fact that many patients develop phage spontaneously. One case is particularly interesting.

> A specimen of fæces, collected on the fourth day of illness, just before the administration of the first dose of therapeutic phage, was found to be rich in a phage with the following activities: Shiga +++, Flexner ++, Hiss +++, Paracolon No. 2+++. Yet clinical improvement only dated from the administration of the therapeutic phage. The particular therapeutic phage used in this case possessed activities which were slightly different—i.e., Shiga+++, Flexner+++, Hiss++, Paracolon No. 2—.

This is obviously a patient who would eventually have recovered of his own accord. The therapeutic phage by mouth merely accelerated the cure and constituted the "reinforcements" necessary to ensure a rapid phage "victory" in the phage-bacterial engagement already going on in the patient's intestines. From this and other considerations I have not the slightest doubt that the spontaneous development of phage will explain most of the bacillary dysentery "cures" due to emetine and simple saline treatment.

FIG. 1.



Showing the percentage of successes and failures, under the influence of phage treatment in 62 cases of various age-periods.

Causes of Failure of Phage Therapy.

Three factors exert an influence on the success or failure of the treatment: the age of the patient, the number of days' illness before the phage intervention, and the bacterial flora. The 62 cases arrange themselves in terms of success and failure as set out in Table I.

These numbers are represented diagrammatically in Fig. 1.

TABLE I.

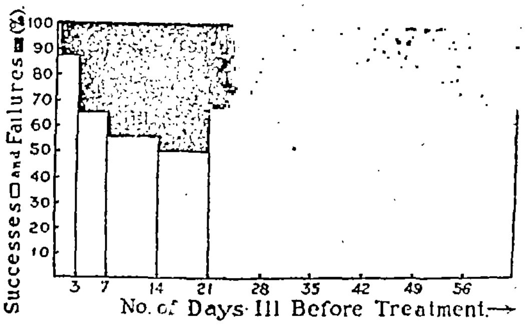
Age.	Number of cases.	Percentage.	
		Successes.	Failures.
Under 1 year	6	16·7	83·3
Between 1 and 2 years ..	15	53·3	46·7
" 2 and 4 " ..	9	66·7	33·3
" 4 and 10 " ..	9	77·8	22·2
From 10 years upwards ..	23	100·0	0

The phage treatment was least successful with children under 1 year old. It was three times as successful with children between 1 and 2, four times better with children between 2 and 4, and still more successful with children between 4 and 10, to reach complete success with adults.

Table II. sets out the arrangement in time-periods of the 62 cases in which definite information was obtained of the number of days of illness before phage treatment.

These numbers, represented diagrammatically, give Fig. 2.

FIG. 2.



Showing the percentage of successes and failures of phage-therapy in dysentery, in terms of the number of days patient was ill before the intervention with phage.

TABLE II.

Days ill.	Cases.	Percentage.	
		Successes.	Failures.
1–3 ..	15·5	87·1	12·9
3–7 ..	27	64·8	35·2
7–14 ..	13·5	55·5	44·4
14–21 ..	3	50	50
21–60 ..	3	66·7	33·3

The success of treatment varies inversely as the number of days the patient was ill before it was commenced. Thus, if the patient had been ill for three days or less about 90 per cent. success was obtained, while when treatment was delayed until the fourth to seventh day the success was about 65 per cent. When treatment was commenced one to two weeks after onset, a success of 55 per cent. only was reached; when it was delayed for three weeks, a fifty-fifty result was obtained. Beyond three weeks, and up to two months, the diagram records a certain improvement in the percentage of successes. The need for early intervention therefore is established. It might be better not to wait for a preliminary purging but to administer the phage at once and to give salines afterwards. There is one instructive case in the series which was treated very successfully in this way.

If the microbes causing the intestinal lesions are not attacked by the phage, obviously no good can be expected from its administration. Cultural studies were made of the majority of the cases, but only in six was the flora completely determined before and after phage administration. Two were successful phage-therapy cases, two were immediate failures, and two were complete failures. They are summarised in Table III.

TABLE III.—*Bacterial Flora Before and After Phage in Six Cases.*

Case.	Age in years.	Days ill before phage administered.	Bacterial flora (as isolated on Endo's medium).		Result of treatment.
			Before treatment.	After treatment.	
2	8/12	7	Coliform only.	Two atypical *B. dys.* (Gay) types.	—
25	2½	4	*B. proteus* No. 2.	*B. proteus* No. 2, *B. proteus* No. 3, *B. paracolon* No. 1, and a *B. meta-dys.* (unknown).	—
27	3	3 (1)*	*B. proteus* No. 2.	*B.C.L.A.* No. 2 or 5, *B. lactis aerogenes.*	+
33	4	1	*B. dys.* (Sonne) *B. paracolon* No. 1.	*B. lactis aerogenes*, and an unknown bacillus of the dysentery group (*a*).	+ + +
36	5	3 (1)*	*B. proteus* No. 2.	*B. morgan* No. 1, *B. lactis aerogenes*, an atypical *B. dys.* (Gay), and a *B. meta-dys.* (unknown).	+
40	6	2	*B. dys.* (Hiss).	Coliform only.	+ + +

* Third day ill, but first day of "blood and mucus" in stools. The cases were sister and brother respectively.

(*a*) Fermenting glucose, maltose, and saccharose, but not mannite or dulcite.

The two cases (Nos. 33 and 40) which did well on phage-therapy had classical *B. dysenteriæ* (Sonne and Hiss respectively) present in the stools before the administration of phage, while, after phage administration, these organisms could not be recovered on culture from the stools: in the one case 30 hours after commencing the treatment, and in the other on the fourth day. *B. proteus* No. 2 is practically constant in the failure cases. This is very striking. Its absence, before and after, in the successful cases is equally noteworthy. It suggests, I think, the need for the revision of our ideas concerning the rôle of *proteus* organisms in the summer diarrhœas of children and the bacillary dysenteries of adults. Most authors consider them rather as concomitants. I suggest that the presence of *proteus* organisms, more especially *B. proteus* No. 2, constitutes an ætiological factor of considerable importance in bacillary dysentery, particularly in children. This organism only differs from *B. morgani* No. 1, so frequently found in summer diarrhœa, by liquefaction of gelatin and by failure to produce indol. It is, I think, chiefly because of its presence that the results of phage-therapy were so disappointing in the cases under two years old. To combat *proteus* organisms by phage-therapy is fraught with difficulty, because the *proteus* group of bacteria is not homogeneous, as is the dysentery group, in its susceptibility to phage action; and because *proteus* organisms are rich in specific endotoxins, allied to botulinus toxin though less powerful. There is, therefore, no guarantee that a phage active against a *B. proteus* causing trouble in one intestinal tract will be active against the *B. proteus* of another case. Moreover, lysis in vitro of the bacterial bodies of *proteus* organisms, by liberating their contained toxins which pass into the filtrate, may render such a liquid too toxic for immediate therapeutic use.

d'Herelle (1926[3]) records having isolated two races of bacteriophage which, at the moment of their isolation from the stools of two infants who had died of infantile cholera, were very virulent for *B. proteus vulgaris*, yet of 12 strains of *B. proteus* only three were found susceptible, and they were the same for each of the two races. Again, he found the [illegible] a bacteriophaged suspension of *B. prot*[illegible] extremely toxic for rabbits immediately [illegible] solution of the bacilli (0·5 c.cm. [illegible] causing death within a few hours). W[illegible] ever, for 10 days the toxicity had [illegible] rabbit then surviving the intravenous [illegible].

Summary.

The general result of phage treatment for bacillary dysentery appears very much in its favour: 70 per cent. of the cases showed a well-defined response and rapid improvement. The good effect was the more marked the earlier the treatment was begun; it was relatively less favourable the younger the patient. It was particularly successful in patients aged 10 years and upwards. Cases with *proteus group organisms*—especially *B. proteus* No. 2—in the intestinal flora did not do so well.

Incidentally, during the progress of the treatment and side by side with it, a noteworthy lowering in death-rates from dysentery was recorded. Whether this is a simple coincidence, or affords evidence of a cause-and-effect relationship, it is not at present possible to affirm. During the investigation there undoubtedly occurred a certain dissemination of the living ultra-virus *Protobios bacteriophagus dysenteriæ* in the surroundings of the patients, with a probable dissemination of natural protection. Distribution of phage to patients in a region means an increased proportion of phage "carriers" among the population, with, in all probability, a correspondingly increased distribution of phage to food and drink. Here doubtless the fly—the great distributor of dysentery bacteria in nature—may reasonably be assumed to play a rôle.

My best thanks are due to the many colleagues—representatives of the Air Forces, the Army, and the civil practitioners in Alexandria, too numerous for individual mention—who kindly collaborated with me in this investigation.

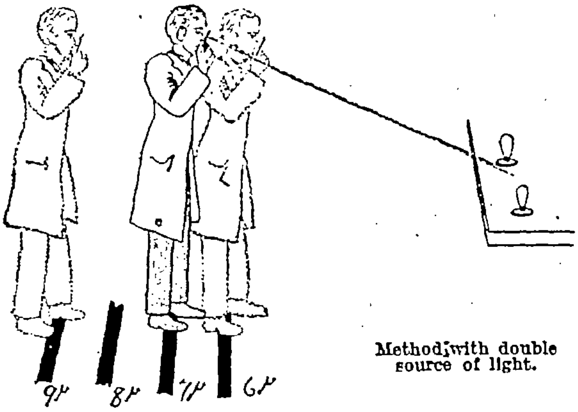
"halos" can be made to meet, overlap, or separate. The distance at which contact is made between a selected pair of corresponding rings is directly proportional to the diameter of the red blood corpuscles. The coloured ring which is easiest to use is the red fringe of the innermost complete spectrum (Spectrum of first order).

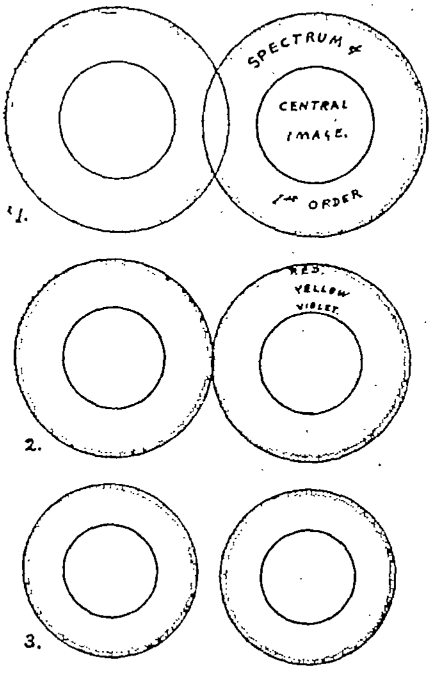
FIG. 1.



Method with double source of light.

The patient's blood-film is examined at the position of contact for the normal. Any difference in the size of the "halos" is shown by overlapping or separation of the selected diffraction rings (see Fig. 2). For example, in pernicious anæmia the "halos" are obviously smaller, and it is necessary to step back a distance which is proportional to the increase in the size of the red corpuscles. If the method is adopted as a routine the floor may be calibrated with chalk lines, so that one foot corresponds to 1 μ. This is done by adjusting the distance between the lamps so that, with normal blood-films, apparent contact is made at a distance of 7 feet. They will then be about 2 feet 4 inches apart.

FIG. 2.



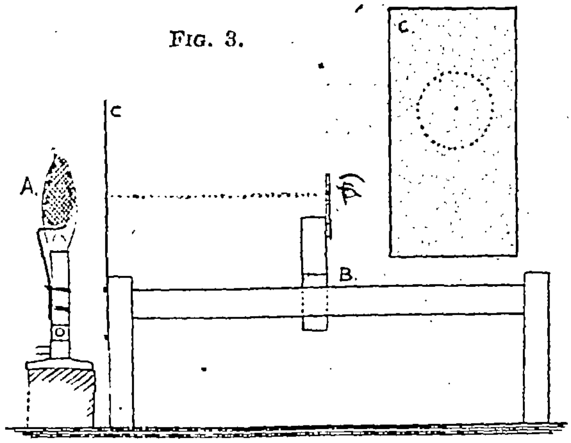
Twin spectra of (1) acholuric jaundice, (2) normal, and (3) pernicious anæmia blood-films at position of contact for the normal.

This method requires no special apparatus, is quite sufficient for diagnostic purposes, and could easily be used by the general practitioner in his ordinary consulting room.

Second Method.

This method, devised by Thomas Young (1773–1829) and described in text-books of physics under the heading of Young's eriometer,[4] is admirably suited to the present purpose. The apparatus required, which is easily constructed, consists of: (A) A source of light (sodium flame or electric lamp). (B) Optical bench with rider for carrying blood-film. (C) Metal plate with a central aperture 1–2 mm. in diameter, surrounded by a ring of 2 cm. radius, of pin-point holes. (The measurements are, of course, arbitrary.)

FIG. 3.



Young's eriometer.

A dark room is necessary when using sodium light, but is not essential for white light. On looking through the blood-film, diffraction rings are seen around the central aperture in C, whilst the ring of holes appears as a circle of luminous points. The film is moved about until apparent coincidence is obtained between the circle of luminous points and a selected diffraction ring (say the yellow of the spectrum of the first order). The distance of the film from the metal plate at which this takes place varies directly as the diameter of the red corpuscles. Since the diameter of the normal corpuscles is known, that of the patient's corpuscles can be calculated by simple proportion. With sodium light, concentric yellow rings are seen instead of spectra. Readings are taken for both borders of a selected ring (say the first). The difference and the mean correspond with the anisocytosis and average size respectively.

My thanks are due to Dr. Wilfrid Newcomb and Mr. Leslie Paton for their kind and valuable advice.

A CASE OF
LOBAR PNEUMONIA IN A CHILD.

BY KENNETH McFADYEAN, M.R.C.S. ENG.

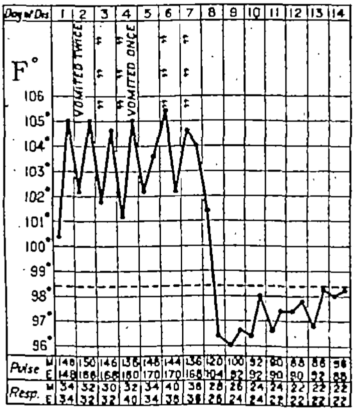
THE following case seems to be worth recording because it illustrates some of the difficulties of diagnosing pneumonia in children:—

A girl, aged 5¼ years, complained of earache on Dec. 5th. On the 6th, in the early afternoon, she said she felt cold, and was put to bed with a temperature of 100° F. She was first seen by me at 8 P.M. on that day, when a diagnosis of lobar pneumonia was made. There were definite alterations in the breath sounds and some crepitations over the lower left lobe, and a few fine crepitations scattered over a small area inside the right scapula. The right tympanum was inflamed, but this was not considered serious. During the night of the 6th–7th there was a small quantity of blood and straw-coloured discharge from the right ear.

On Dec. 7th a consulting physician saw the child at 9 A.M., and was satisfied that there was nothing abnormal in the chest, but was of the opinion that there was mastoid inflammation. At noon an aural surgeon saw the case. In his opinion the mastoiditis was acute, and was the cause of the child's general condition. He advised surgical interference unless the general condition improved in 24 hours. At 9 P.M. a second consulting physician saw the child and was satisfied that his examination of the chest was negative. He advised surgical treatment of the aural condition. At 10 P.M. a second aural surgeon expressed the opinion that the mastoiditis was slight, and that the case should be watched.

On Dec. 8th the inflammation in the right ear was definitely subsiding. There was very little swelling in the meatal floor, the tympanum was pink, there was no aural discharge, and no perforation was seen. There was no longer tenderness over the mastoid. In the evening the patient complained of occasional severe stabbing pains in the chest over the lower left ribs in the axillary line.

On Dec. 9th a consulting pathologist found a leucocytosis of 22,400 per c.mm., with 77 per cent. polymorphonuclear leucocytes, and expressed the opinion that this "indicates the presence of pus under tension." All signs of inflammation in the ear had subsided. In the afternoon the patient's condition seemed serious. The signs in the left lower lobe were now well marked. The first consultant, on *re-examining* the patient's chest, expressed the opinion that possibly the patient had a miliary tuberculosis. Albumin was present in the urine. Subsequent examination showed that the degree of albuminuria varied considerably, and was very severe when the temperature was between 105° and 106°, and at a time when the child was drinking considerable quantities of albumin water.



The treatment of the case as one of pneumonia was instituted at the outset and continued. On Dec. 13th the crisis set in, with definite signs over the left lower lobe. In 24 hours the temperature dropped from 104° to 96°, pulse from 170 to 108, respiration from 36 to 26. The patient made an uneventful recovery.

The case presents some striking features, of which one or more is frequently to be found in cases of infantile lobar pneumonia. These are, firstly, the liability of an error in diagnosis when an acute otitis media is present in the early stages; secondly, the difficulty of making a correct diagnosis when relying solely upon one examination of the chest, made at a particular moment during the illness; thirdly, the possibility of attaching undue weight to the presence of albuminuria in this condition; and lastly, the fallacy of regarding a high leucocytosis as necessarily indicative of pus. One other unusual feature, rarely seen, was the persistent vomiting.

All these features of the case are adequately dealt with by Dr. G. F. Still in his "Common Disorders and Diseases of Childhood."

London, S.E.

A CASE OF
HYPERTHYROIDISM WITH MANIA.
RELIEVED BY OPERATION.

BY J. MURRAY BLACK, M.B., F.R.C.S. EDIN.,
HON. SURGEON TO THE DUNFERMLINE AND WEST FIFE HOSPITAL.

IN his selection of cases for operation Mr. W. H. O. Romanis[1] holds that "in serious mental changes of the melancholic or maniacal type" operation is absolutely contra-indicated. The following case, however, suggests that maniacal symptoms can sometimes be relieved by operation.

Mrs. A. B., aged 42, whose husband was abroad, was brought to consult me in February, 1929.

In 1919 her relations noticed that her eyes were protruding and she was taken to Edinburgh Royal Infirmary where she was advised to have an operation on her thyroid, but refused. Since then she has had gradually increasing ill-health, palpitation, headaches, insomnia, tremor, and marked loss of flesh. In 1921 she was taken to consult a doctor and because of her maniacal symptoms she was certified insane and spent six months in an asylum. Since then, though her general health had improved, she continued to show symptoms of cerebral derangement, writing letters of abuse to her relations, locking herself in her house, and on one occasion trying to set fire to herself. Her family history is negative as regards insanity.

In February, 1929, against her will but with the permission of her relatives, she was admitted to the Dunfermline and West Fife Hospital under my charge. On admission she was quite irrational and her behaviour was that of a maniac. She was under the delusion that her relatives had employed me to get rid of her. There was marked exophthalmos and tremor. The pulse-rate was 120 per minute. The thyroid was *symmetrically enlarged* with distended and pulsating veins over the front of the gland. Her teeth were in very bad condition but she refused to have them touched. She refused enemata and hypodermic injections, but was persuaded to take Lugol's solution minims x. t.i.d. and luminal at night.

After 15 days in hospital her mental condition was not improved though her pulse-rate had fallen to 84. On the sixteenth day she was taken to the theatre and under open ether a subtotal thyroidectomy was performed. Forty-eight hours after operation she was quite rational. Twenty-two days after operation she was discharged, her condition mentally having undergone a complete alteration. Her pulse-rate was 60 per minute and her tremor had disappeared.

In July, 1929, she reported having had her teeth extracted. She is living now in peace with her relations who state that her mental condition is normal. Her exophthalmos and other physical signs are now gone and she appears to be a sane woman again.

According to Dr. John Eason, these symptoms of mania may be due to: 1. The action of the toxæmia of hyperthyroidism on the cerebral cells (this is not proved). 2. The effect of various cardiovascular disorders characteristic of exophthalmic goitre upon the cerebral circulation. 3. Coincident focal infections causing toxæmia.

If the mental symptoms are due to either (1) or (2) then, as in the present case, operation for the removal of the toxic thyroid gland appears to me to be the proper line of treatment.

---

[1] THE LANCET, July 20th, p. 113.

WEST KENT JOINT ISOLATION HOSPITAL.—Lord Cornwallis, Chairman of the Kent County Council, last week opened a new administrative building and nurses' hostel at the West Kent Joint Isolation Hospital at Bromley Common, an institution which serves the borough and rural district of Bromley, and the urban districts of Beckenham, Chislehurst, and Sidcup, with an estimated population of 130,000. Each of the 40 nurses has a separate room, and the administrative offices are extensive enough to provide for the needs of the hospital for many years to come.

BRITISH MEDICAL ASSOCIATION.

ANNUAL MEETING IN MANCHESTER.

(Continued from p. 231.)

SECTION OF MEDICINE.

TREATMENT OF PLEURITIC EFFUSIONS.

Opening Addresses.

Prof. G. R. MURRAY (Manchester) took the chair at a discussion on this subject opened by Sir THOMAS HORDER. The factors to be considered, he said, were the cause of the infection, the nature and size of the effusion, the stage of the disease, the associated condition of the lung, the degree of illness of the patient, and the contribution made by the effusion, as such, to the illness at the time. The traditional division of effusion into serous and purulent was, he thought, justified. Serous or sero-fibrinous effusions might be tuberculous (primary), rheumatic, influenzal, lymphadenomatous, or neoplastic. They might also perhaps be caused by some other infections besides those mentioned. Purulent effusions (i.e., empyema) might be pneumococcal, streptococcal, staphylococcal, and influenzal (mixed infections), and occasionally gonococcal, coliform, or a result of streptothrix infection. The stage of disease was very important. To remove all effusions on sight was bad practice, whether they were serous or purulent. The associated condition of the lung must be assessed as carefully as possible. Cæteris paribus, active and acute disease of the lung contra-indicated removal of the fluid, since the fluid kept the lung at rest. It was important to decide how far the patient was handicapped by the fluid—whether in toxic or mechanical fashion—and how far he was ill by virtue of his general infection. The more the illness was the result of the general disease, the more carefully and slowly should the effusion be removed.

Most serous effusions, continued Sir Thomas, were tuberculous. If very large, they should be tapped as soon as diagnosed; they should also be tapped if associated with cardiac or respiratory distress. The remainder were tapped if they showed no further signs of absorption after fourteen days from their discovery. Too early interference was meddlesome; too late interference might lead to permanent collapse of lung with chest deformity. The possibility of latent tubercle in the lung must always be borne in mind, and until the case had been properly studied its existence must be assumed. If disease of the lung was established, a conservative policy as regards the effusion was imperative; otherwise there was fear of renewed activity or even pyopneumothorax. Oxygen replacement might be undertaken. Throughout, and afterwards, the patient with no manifest signs of pulmonary disease was treated as though this was present in its early stages. General treatment was instituted; iodine and calcium might be given internally; the arm should be immobilised and the chest strapped on the affected side. In removing serous effusion slow aspiration was probably preferable to syphonage. Injecting drugs into the pleural cavity was of doubtful value, and autoserotherapy had at present too little to its credit to justify more extensive trial. Recurrent effusion might call for the trial of adrenalin or paraffin. Exhaustion by Potain's aspirator must be done carefully and slowly, the last few ounces need not be considered, for they would be rapidly absorbed. A cigarette for the doctor, said Sir Thomas, would give improved results. Local anæsthesia should be effective, and a nick with a sharp scalpel was of considerable value. The ritual of major operations was uncalled for. The volume of fluid removed might require judgment. After-care should be controlled by the tuberculous nature of the disease, and the patient should not return to active life within three months.

Rheumatic effusions were part of an acute and general rheumatic inflammation, carditis being present. Tapping the effusion was rarely necessary. In influenza the effusion was either present with pneumonia—when it should be dealt with palliatively—or followed the acute stage of the disease, when it should give rise to suspicion of tuberculosis.

In empyema, Sir Thomas Horder continued, the surgical maxim, "Evacuate pus as soon as diagnosed," should not be departed from. The time factor was of great importance. The more ill the patient and the more active and extensive the disease in the lung, the more was aspiration indicated and the less was an open method of drainage indicated. One or two aspirations might be all that was necessary, not only in pneumococcal, but also streptococcal disease. When the patient remained very ill, and/or the lung actively diseased, and freer drainage than that given by repeated aspiration nevertheless seemed desirable, trial might be made of incision without resection. As soon as might be, however, the ideal method should be employed—viz., incision with resection of portion of a rib or ribs. Treatment by incision (with or without resection), irrigation, and closure of wound, was successful in some pneumococcal cases, but too often entailed recourse to the open method later to be recommended. It should never be relied upon in streptococcal or staphylococcal cases. Digital exploration at resection operations was of great importance; it broke down adhesions and gave useful information. The question of irrigation of the empyema cavity frequently recurred. Pleural shock might, in the main, be disregarded, but experience scarcely warranted even this risk or the added pain suffered by the patient. Before employing the method coexistent pulmonary abscess should be excluded. The fact that the number of substances used for this purpose was very large suggested that the method lacked adequate justification by results. Of greater importance was the mode of drainage. Perhaps the best—though difficult in children—was to use a closely fitting tube, of considerable length, ending in an air-tight bottle. Such a device allowed of slow drainage and avoided a pneumothorax.

It must never be forgotten, Sir Thomas concluded, that the patient was suffering from a septic disease and also from a respiratory disease. Hence the general measures appropriate to both of these should never be omitted—e.g., ærotherapy, heliotherapy, actinotherapy, and immunotherapy. Residual sinuses should be treated by X rays and sunlight. Failure of the lung to expand would necessitate decortication or Estlander's operation.

Dr. L. S. T. BURRELL (London) directed attention at the outset to two factors—the nature of fluid and the cause of its effusion. Fluid due to heart failure should be removed at once. Of the clear fluids he recognised only tubercle as a cause; the reported rheumatic and other effusions were probably at origin also tuberculous. For treatment the primary question was always whether to aspirate or leave alone. He thought that in all cases the first thing to do was to remove 5 c.cm. for examination. Clear fluid was to be left severely alone, except (*a*) to relieve pressure by removal in part, (*b*) to convert effusion into pneumothorax, (*c*) to allow a lung to expand when its opposite fellow was extensively diseased, or (*d*) to treat a chronic or recurrent effusion. Removal of large volumes of fluid was not without danger; it might cause dyspnœa, or more commonly it might start an acute flare-up of a tuberculous process. Dr. Burrell stated the rule that fluid volumes over 50 ounces should be replaced by gas, selecting air for prolonged action, and oxygen for temporary effect. Fever, he said, was responsible for the degree of illness and the effusion of the fluid, and both would settle down if left alone. Early intervention caused exacerbation in most cases.

In the very chronic cases, among which neoplasm was so common, the treatment he recommended was removal of the fluid, lavage with Carrel-Dakin solution, and filling of the cavity with oxygen to a pressure of minus 6.

After-treatment was of the greatest importance, for over 45 per cent. of cases ultimately developed active pulmonary involvement, and prolonged sanatorium treatment, with its graduated exercises and education in personal hygiene, was essential.

In purulent exudates a clear difference between pyothorax and no pleural adhesion on the one hand, and empyema with its localisation by adhesions, was the key to treatment. In pneumococcal empyema the lesion appeared when the primary illness was over, and the pus was localised as an empyema. Operation was then successful and no pneumothorax was created. In acute influenzal pneumonia a pyothorax arose in the course of the illness; the fluid was thin and milky. Operation then caused complete pneumothorax, the flexible mediastinum allowing the pressure in the opposite lung to fall also, and death resulted. The presence or absence of pleural adhesion was the key to the treatment; the healing of cavities closed by adhesions could be hastened by Dakin irrigation, which promoted both sterilisation and healing. Thoracoplasty was still sometimes necessary, but should be regarded by the physician as a sign of the failure of his treatment; much might often be done by pleural lavage to avoid it.

Prof. A. RAMSBOTTOM (Manchester) referred to the frequency with which pyrexia in these cases lasted for three weeks, during which time of active disease the fluid could best be left, no damage to the lung resulting. Its removal during the pyrexial stage often led to its reaccumulation, and, provided it was not purulent nor the signs of positive pressure very marked, the fluid was best left alone. The problem of removal of small effusions during the active period of influenzal pneumonia was a difficult one. His practice was to wait until the end of the fourth week, for many effusions resolved within that time; but if the chest wall was tender to pressure over the fluid, then removal at once was indicated. The damage done by removal of pleural fluid was said to be exaggerated, and pleural shock was never seen if it was removed at the rate of ten minutes to the pint.

Discussion.

Dr. WILLARD STONE (California) recounted his experience of empyema in a base hospital, during an epidemic of hæmolytic streptococcal infection, in which 25 per cent. of the residents were found to be carriers. An outbreak of measles was followed by a large number of empyemas, most of them bilateral. Early diagnosis was followed by early operation, the formation of an open pneumothorax and a mortality of 64 per cent. Treatment by repeated aspiration with Potain's aspirator was started to replace operation until after the fourteenth day. This measure reduced the mortality to 8 per cent. Dr. Stone referred to the use of novocaine as a local anæsthetic, and to the use of Brewer's tube, when drainage was required, to form a closed thorax and permit irrigation with Dakin's fluid. The four complications found in the empyema cases were purulent pericarditis (25 per cent.), purulent peritonitis, septic nephritis, and meningitis. The best time to operate on these pyothorax cases seemed to be the 12th–14th day, and the use of antistreptococcal serum appeared to give no help.

The CHAIRMAN thought that when fluid exudates reached the level of the fourth rib, they should be removed at the rate of ten minutes to the pint. The operation should be rendered painless, and he suggested local freezing and the use of a trocar. The Potain aspirator should not be violently exhausted from time to time, but partly exhausted, the negative pressure being maintained by gentle strokes of the pump as required. Full pulmonary expansion after larger effusions was best obtained at high alpine altitudes.

Dr. RUSSELL objected strongly to the great interference with working life, and the mental agony inflicted by a tuberculous outlook in these cases. Treatment by ordinary means was quite satisfactory. A large proportion of autopsies showed tuberculous lesions; therefore prolonged and expensive arrangements, as required by the sanatorium, were unnecessary.—Dr. ASTON KEY spoke of the frequency with which empyema was overlooked in small children, and Dr. ASTLEY CLARKE referred to the use of the boracic immersion bath, and the frequency of sudden death in babies suffering from empyema.—Dr. J. SPEARES mentioned the difficulty of treating chronic sinuses after empyema operation. Breathing exercises as practised in Vienna were valuable.

SECTION OF PATHOLOGY AND BACTERIOLOGY.

BACTERIAL FOOD POISONING.

Prof. J. SHAW (Manchester) DUNN presided over this Section.

Prof. J. CRUICKSHANK (Aberdeen) opened a discussion on the Distribution and Characteristics of Bacterial Food Poisoning. The sporadic nature of outbreaks, the dramatic onset of symptoms and frequent difficulty in tracing the cause, he said, excite interest in all the medical men, but the unexpectedness of the outbreaks both in time and locality hinder systematic investigation. The characteristic symptoms are sudden onset of nausea vomiting, severe diarrhœa, abdominal pain, and pyrexia. The interval between the taking of infected food and the onset of symptoms is short, varying from 2–30 hours. In the majority of cases severe symptoms persist only for a short time, and within 24 hours the patient suffers only from exhaustion. Pyrexia is of short duration, and may be absent. Blood and mucus are rarely found in the stools—a distinguishing feature from dysentery. The extremely short incubation period in some cases has suggested that symptoms result from preformed toxins, and in certain outbreaks there is clear evidence that the suspected food has been subjected to such exposure of heat as would ensure death of all vegetative forms of bacteria.

Since the discovery of Gaertner's bacillus in 1888 a large number of organisms closely allied in morphological and biochemical reactions have been described as the cause of food poisoning in man, or severe enteritis in animals. These organisms are closely allied to *B. paratyphoid* B. The organism most frequently found is *B. aertrycke*. This and closely allied organisms have been demonstrated in the intestines of animals. With extension of bacteriological methods the list of food poisoning organisms is constantly being lengthened, and in many ways has made the problem more difficult, especially for the routine bacteriologist.

An important feature in most outbreaks is that the food is not obviously unsound; this affects investigation, since if all the food has been eaten the cause may remain obscure, unless an organism of the salmonella group can be isolated from the patient's vomit or stools. However, there may be indirect evidence, such as blood agglutination. A puzzling feature in some outbreaks is the small number of individuals affected, although the infected material has been widely distributed. Individual susceptibility, or partial infection of the material, may be the explanation. According to W. G. Savage, human carriers are not to be regarded as playing an important part in infection, but the possibility cannot be excluded.

Among the foodstuffs which have been found to be associated with food poisoning tinned meats are especially important. The possibility of infection from eggs has been raised in a recent case, and it has been shown that severe diarrhœa in chickens and ducks may result from infection with *B. aertrycke*. Milk offers suitable conditions for growth of the organisms, and where this food is the vehicle outbreaks are widespread and severe. When fresh meat is incriminated, the animal from which the joint is cut may have been the subject of salmonella infection. The way in which tinned foods become infected is not clear. It is necessary to suppose that individual tins are infected from an unknown source, and that considerable growth of the organism has occurred with the development of "toxins" which are heat resisting. Prof. Cruickshank observed that he had great difficulty in accepting the explanation attributing outbreaks to toxins. It would be necessary to postulate a time interval for the development of toxins, and in many outbreaks there is no evidence that these conditions were present. It was inconceivable to him that a few dead organisms could be held responsible for the pronounced symptoms of food poisoning.

With regard to infection from meat of animals, he continued, it is believed that the source of infection arises from the soiling of meat with intestinal contents. If the view of Savage be accepted, that heat stable poisons are the cause of these outbreaks, we must suppose that the organisms have developed in large numbers between the death of the animal and cooking. The infrequency of *B. Gärtner* and *B. suipestifer* in these outbreaks is important, since these types appear to be the most frequent exciting agents of disease in cows and pigs. The occurence of *B. aertrycke* in the diseases of food animals is extremely uncommon, yet *B. aertrycke* is the most common finding in human outbreaks. The view strongly advocated by Savage that salmonella infections account for all food poisonings except those definitely chemical has led to the concentration of investigation upon the discovery of this group of organism with the result that other possible bacterial causes may be missed. A great extension of the bacteriological methods used in attempts to solve the problem of food poisoning is desirable. Evidence of invasion of the blood stream by organisms is rarely obtained, but the development of agglutinins to salmonella organisms occurs frequently. The difficulty of producing agglutinins in experimental animals by administration of the organisms through the alimentary tract makes their occurrence in food poisoning cases all the more remarkable, since their production in the blood is a common phenomenon after parenteral injection of living or dead bacteria. The presence of antibodies in the blood suggest that a living organism is responsible rather than preformed toxins. Savage and Bruce White record the development of agglutinins in rabbits as a result of feeding boiled cultures of *B. aertrycke*, and Geiger and Meyer after feeding to mice and a monkey. The development of agglutinins in rabbits after repeated injections of extracts of suspected meats shown by Savage and White is of little value since the titres obtained are very low.

Much interest lies in the question of the production of heat resistant poisons by salmonella organisms. Savage and White have supported the view that such toxins give rise to food poisoning, but the enormous number of organisms used by them produced only slight lesions; it is impossible to believe that any portion of meat producing poisoning in man could contain such numbers. Unless man is extremely susceptible, these experiments fail to convince. Several workers have obtained negative results by administration of toxin and killed organisms by mouth. On the other hand, Geiger and Meyer claim to have produced definite lesions with a heat resistant toxin derived from *B. aertrycke.* The animals used were mice. Rabbits, guinea-pigs, and cats usually presented very transitory symptoms, and it is remarkable that such difficulty should be encountered in producing toxic manifestations in animals which are frequently the subjects of natural infection. Further experiments on monkeys may prove of value. As a result of a survey of epidemics of paratyphoid fever, Savage and White have come to the conclusion that symptoms of food poisoning are absent in these outbreaks. In some cases, however, the symptoms of food poisoning definitely occur; it is doubtful whether a rigid separation of food poisoning from paratyphoid fever is justifiable on clinical grounds. On the other hand, organisms of the *B. suipestifer* group may produce symptoms resembling typhoid fever. The outbreak of food poisoning due to *B. aertrycke* in our troops in France, recorded by Perry and Tidy, suggests that a chronic carrier was the cause of initiation of the outbreak. In civil life the outbreaks are rarely examined so minutely. The work of Bruce White on the salmonella group is of great importance, especially in showing that the organism isolated in the majority of cases of food poisoning is *B. aertrycke.* The problem of the source of infection still remains obscure.

Discussion.

Dr. W. G. SAVAGE (Weston-super-Mare) said that he did not consider that all cases of food poisoning were due to salmonella organisms, nor that human carriers could be completely excluded as possible source of infection. Dr. Savage dealt at some length with the possibilities of the occurrence of preformed toxins. He considered that the evidence justified the claim that such toxins can be formed by salmonella organisms; from his investigation of the canning process in America, he found that a time interval was often present between obtaining the meat and canning it. The food was undoubtedly sterile when eaten, and the time incidence of occurrence of symptoms greatly supported his view. The apparent lack of support obtained in animal experiments he considered to be due to the comparative greater susceptibility of man to these toxins.

Mr. P. BRUCE WHITE (London) dealt with the classification of organisms of the food poisoning group. Several genera were believed to be implicated, and dysentery and salmonella groups were definitely associated with the disease. A very large number of species had been described; many of which were not separate types, but the introduction of agglutination tests had led to systematic classification. The speaker described the specific and non-specific antigen character of members of the group.

Dr. W. SCOTT (London) described interesting and important evidence to show that eggs may be responsible for certain cases of food poisoning. He described several outbreaks of food poisoning in which all possible infection, other than eggs, had been excluded, and although there was no absolute proof, circumstantial evidence tended to show that eggs were responsible. Duck's eggs appeared to be far more dangerous in this respect than hen's eggs. An epizoötic among ducklings was described, in which *B. aertrycke* had been isolated. There was some doubt as to the way that eggs become infected. It had been suggested that introduction of foreign material into the oviducts during copulation might infect the white of the egg. Eggs placed in a fluid culture of *B. aertrycke* might become infected, but negative results had been obtained with dry cultures. Ducks fed with *B. aertrycke* passed large numbers of these organisms in their excreta. The dry surroundings that hens chose for egg-laying might account for the smaller liability to infection of their eggs. The great importance of recognising that eggs might be a source of infection lay in the fact that many of the single sporadic cases of food poisoning which occurred might be explained in this way, since eggs were probably the most common unshared dish consumed in this country.

Dr. D. NABARRO (London) discussed the relation of food poisoning to dysentery. He pointed out that dysentery is not uncommon in children in this country, and that the possibility of this infection should be always kept in mind in suspected cases of food poisoning.

Bacillus Abortus Infection in Man.

Dr. W. D. CHAMPNEYS (London) read a paper on *Bacillus abortus* Infection in Man. He showed that the number of cases of this disease recorded in European countries was steadily increasing now that it is recognised that an undulant fever can be produced by an organism which belongs to the same (brucella) group as *Micrococcus melitensis* and occurs in cow's milk. In addition to those who might acquire infection from drinking milk, persons handling living and dead cattle might be subjects of infection. The organism responsible, *B. abortus*, was killed by pasteurisation. This organism had been injected into human beings by some workers without the production of harmful effects. The symptoms of the infection were almost identical with those of Mediterranean fever, and accurate diagnosis could only be made by hæmoculture and agglutinin tests. Injection of suspected blood in guinea-pigs was an excellent method of investigation. The speaker believed that if systematic examination for brucella infection was made in cases of pyrexia of obscure origin, the number of cases of this infection would probably be found to be much greater than was suggested by the present statistics.

Prof. MEYER (California) communicated a paper which was read in his absence. He had investigated various strains of the brucella group, and described variation in virulence of various strains in monkeys. He pointed out that many individual animals possess a natural immunity for such infections. Cultures kept for long periods tended to lose their virulence.

Dr. G. ROSS (Rhodesia) described the occurrence in Africa of cases of undulant fever due to *B. abortus*. He had made systematic examination of cases of pyrexia, which had been diagnosed as such conditions as phthisis and influenza, and found them to be brucella infections. If attempt at hæmoculture was made, patience was necessary, since the organism rarely appeared in the first six days, and might require 10–14 days. The treatment he considered very unsatisfactory; vaccines were not recommended in the pyrexial stage.

Dr. W. PARRY MORGAN (Cardiff) described four cases of brucella infection which he had investigated, the first occurring in 1912, and two within the last year. He had examined 40 samples of blood submitted for Widal reaction, and found that two of them gave positive agglutination with *B. abortus*. A number of samples of milk had also been examined by injection into guinea-pigs, and 25 per cent. of these developed agglutinins. The *B. abortus* was isolated from some of these cases, but only when it was cultivated in an atmosphere of CO_2. He emphasised the importance of recognising the marked inhibition zone in the serum agglutination.

SECTION OF OBSTETRICS AND GYNÆCOLOGY.

CHRONIC CERVICITIS (LEUKORRHŒA).

Prof. FLETCHER SHAW (Manchester), the President, was in the chair when

Mr. J. BARRIS (London) read a paper on the Ætiology and Symptoms of Chronic Cervicitis. He defined this as an inflammatory affection, involving the mucous membrane of the cervical canal and os uteri externum, characterised by leukorrhœa, erosion, and microscopic signs of inflammation. After describing the anatomy and development of the generative tract with especial reference to the changes in the epithelial lining, the speaker said that bacteria were not normally found above the external os. In chronic cervicitis, however, bacteriological investigation revealed the presence of pathogenic organisms. The invasion might be the result of direct infection, or of indirect infection following injuries to the cervix. Mr. Barris showed figures to illustrate that the condition was most common in the child-bearing period. A consideration of the complications of chronic cervicitis made evident its importance. Mr. Barris described the cervix as the tonsil of the pelvis, and stressed the fact that it may act as a focus of infection. In conclusion, he referred to K.V. Bailey's work on the basic cause of cervical cancer and its relationship to chronic cervicitis.

Mr. G. I. STRACHAN (Cardiff) spoke on the pathology of chronic cervicitis, explaining that the anatomical relations of the cervix were important in this connexion. The essential lesion in cervicitis, he said, is irritation produced by pyogenic infection, most usually brought about by the lacerations consequent on childbirth. There is œdema of the sub-epithelial stroma with outpouring of lymphocytes and plasma cells, especially round the blood-vessels and glands, and under the surface epithelium. The blood-vessels dilate, the surface columnar and glandular epithelium become irritated, so that glandular hypertrophy with distension occurs, and the cervical secretion becomes increased in amount and of a muco-purulent appearance. Some of the squamous epithelium surrounding the external os becomes separated and cast off in the discharge, and the columnar epithelium is stimulated and grows down to cover the raw area, carrying with it in its outgrowth cervical racemose glands giving rise to the appearance described by Eden and Lockyer as pseudoadenoma. In discussing the late results of cervicitis, Mr. Strachan said that the parametrium was frequently affected by lymphatic extension from the cervix, so that in the early stages infiltration and later fibrosis was produced. The parametrial extensions were the most common causes of backache or chronic pelvic pain in women. Absorption of toxins from the chronically inflamed cervical surface led, in some cases, to general ill-health, shown clinically by muscular rheumatism and osteoarthritis. Mr. Strachan pointed out that while severe puerperal sepsis accompanied by pyrexia occurred in about four cases per 1000, puerperal sepsis in a minor degree occurred in a large proportion of all parturient women. Often no symptoms were manifest at the time, but the results of the infection lasted for many years, and carried with them a risk of carcinoma formation.

Dr. R. S. STATHAM (Bristol) spoke on treatment, expressing his personal views. He thought that chronic endocervicitis was one of the commonest causes of sterility and perhaps even more often of the one-child marriage. Mild thickening and inflammation of the pelvic cellular tissues gave rise to pressure on the ureter, with chronic backache and renal pain. This process had been described by Guy Hunner, and had stimulated Dr. Statham to pass ureteric bougies in certain cases of backache associated with cervical erosion, much benefit having ensued. There were two factors to be treated: (1) the leukorrhœa, and (2) the deep infection. Cervical lacerations should be repaired at the time of confinement. In venereal clinics Dr. Statham had observed typical erosions developing in cases of gonorrhœa, as well as in patients complaining of leukorrhœa and cervicitis in whom gonococci were found on further investigation. When gonococci were found Dr. Statham thought that the best treatment was daily douching with boric acid lotion, and when the discharge had been wiped away, thorough swabbing of the cervix and vagina with 1 per cent. mercurochrome. In the cases where there was laceration of the cervix with thickening and tenderness of the bases of the broad ligaments—a mild grade cellulitis—the best results were obtained by prolonged hot douching by a skilled person; in private practice treatment could be carried out while the patient lay in a hot bath. Excellent results were obtained with the diathermy current in certain cases. When no response to treatment was observed, either repair operations or amputations or panhysterectomy should be undertaken according to the indications for the particular case. The speaker did not advise amputation of the cervix in young patients since it predisposed to abortion, and in one of his cases had led to cicatrisation, causing much trouble in labour. In elderly patients, especially in the presence of the so-called "fibrosis uteri," the operation of election was panhysterectomy combined with perineal repair when necessary. If true ulceration was found upon the cervix it was essential to remove a portion for histological examination. Finally, Dr. Statham advocated inspecting the cervix after delivery, and suturing any lacerations immediately.

General Discussion.

Dr. J. YOUNG (Edinburgh) emphasised the importance of erosion as a cause of chronic ill-health such as *arthritis, rheumatism, and chronic heart disease.* He thought that a good deal of abdominal pain could follow cervicitis. Dr. Young considered the best treatment to be a free opening up of the cervix by means of the surgical cautery. He had not encountered ureteral stricture in cases of cervicitis.

Prof. T. CULLEN (Baltimore) said that the cylindrical epithelium of the cervical canal sometimes extended over the vaginal portion of the cervix, whilst he had seen the squamous epithelium reaching almost up to the internal os. He thought that irrigation was going to prove the most efficacious treatment. Referring to operative treatment, he thought that it was sufficient to repair one side only. Prof. Cullen never removed the uterus for prolapse in old women, since it was the keystone of the pelvis. He praised Hunner's work on ureteral stricture.

Mr. L. C. Rivett (London) said that he had closely questioned many patients suffering from cervical cancer, and could not illicit any history of leukorrhœa to suggest preceding erosion ; he had not encountered any patients with leukorrhœa who had developed carcinoma.

Dr. B. Solomons (Dublin) advised a modified Schröder operation under general or local anæsthesia for erosion, and did not think that either mercurochrome or any of the other local applications produced permanent benefit. Many women could be cured by means of constitutional treatment. Hysterectomy should be left to the very last, and only be undertaken after very careful consideration. Dr. Solomons considered it very dangerous to teach students to examine and repair all cervices immediately after labour ; in his view the right procedure was to examine the patients six weeks after the birth of the child, and then carry out any plastic operation necessary.

Dr. C. Forbes (Aberdeen) thought that the products of split protein might be the cause of erosion and leukorrhœa.

Prof. O. G. Lowry (Belfast) referred to the importance of the cervix as a focus of infection, and mentioned an investigation which they had been carrying out on cases of rheumatism, with a view to finding out whether the cervix was the source of infection. He pointed out the difficulty of finding gonococci and in deciding how many cases were attributable to this organism. He did not agree with those who said leukorrhœa caused sterility in all cases.

Dr. K. V. Bailey (Manchester) was chiefly interested in the pathology, and pointed out that the connexion of chronic cervicitis and cancer can be traced histologically. Cancer was the result of a constant contact with chronic irritative exudates of specific types.

Dr. J. Riddell (Plymouth) thought that the term erosion should be dropped entirely for cervicitis. He considered that there ought to be a time-limit for medicinal treatment, and suggested that surgical procedures should be resorted to at the end of six months. He deprecated the adoption of vaginal hysterectomy, and said that the abdominal operation should be chosen in order that a more adequate investigation might be made.

Dr. F. Murray (Newcastle) said that a thorough investigation should be carried out before any treatment was undertaken. He had found that there was often an infected urine which should be treated at the same time. In cases where there had been extensive lacerations of the cervix, reparative operations might be dangerous owing to the close proximity of the large venous plexus and the ureters. He had had excellent results from instilling into the vagina, whilst the patient lay on her back, about two ounces of a mixture of one part of tincture of iodine and two parts of glycerine.

Dr. K. Foster (Worcester) held that the cause of erosion was injury at birth ; proper antenatal care would prevent the need for deliveries by forceps, and would therefore diminish the incidence of erosions.

Prof. I. P. Maxwell (Pekin) said that he had been in the habit of taking a section for microscopical examination from the cervix of every patient whose symptoms did not clear up rapidly under skilled douching (which he had been employing for some considerable time), with the result that he had succeeded in discovering a number of early carcinomata.

Prof. D. Dougal (Manchester) thought that curettage and amputation of the cervix would cure a certain number of cases.—The President did not think enough had been said about cauterisation as a method of treatment. He considered that douching tended to keep up a chronic discharge. Leukorrhœa began to worry the patient as her general health deteriorated, and with improvement of the constitutional condition the discharge produced no discomfort.

Dr. Statham, Mr. Strachan, and Mr. Barris replied.

SECTION OF OCCUPATIONAL DISEASES.

The Present Position of Silicosis in Britain.

The discussion was opened by Dr. E. L. Middleton, H.M. Medical Inspector of Factories, who dealt with (1) the occurrence of the disease in the various industries throughout this country ; (2) the manifestations of the disease as it presented itself to medical practitioners ; and (3) the legislation which had been brought into being within recent years. In a brief review of the ætiology, symptomatology, and pathology of the disease Dr. Middleton remarked that silicosis was produced by the inhalation of particles of silica, and in silicosis, properly so-called, the silica was in the form of free dioxide of silicon (SiO_2)—e.g., quartz or flint. The particles, to produce the disease, must be inhaled into the ultimate pulmonary tissue, and must therefore be of a degree of minuteness which would permit of their free passage in the mid-current of the air through the upper respiratory passages and the finest bronchial tubes. The particles were phagocyted and the lymphatic channels, perivascular and peribronchial, contained deposits of these cells which produced a reaction in the surrounding tissue. Fibroblasts were produced, changing ultimately into fibrous tissue which underwent condensation and contraction resulting in distortion with loss of function of the remaining lung tissue. Foci of tuberculosis were commonly found embedded in the dense fibrous tissue. In some cases no massive fibrotic areas were found, but in both lungs nodules varying in size from 0·1 to 1·0 cm. in diameter were present in large numbers. Sections of the lung showed the nodules to be formed in a characteristically whorled arrangement of fibrous tissue, and often particles which (if 5μ in diameter) could be demonstrated by polarised light.

The inhalation of silica dust was not usually accompanied by evidences of irritation. When free from other dusts of an irritating kind silica might be inhaled by workers without any suspicion that they were exposed to dangerous dust. Herein lay the perils of indifference on the part of the worker and absence of suspicion on the part of the employer. Dyspnœa was usually the first symptom, and in its production two characters of silicosis were important. The first was the cumulative action of silica and the second the latent period for anatomical changes to take place in the lung. Symptoms might follow exposure to silica dust at any time from 2 to 40 years. One of the problems to be solved was : Is the disease recognisable at a stage when removal from exposure to silica dust will not be followed by disablement ? In diagnosis, said Dr. Middleton, the employment history should be exhaustively studied, while a careful clinical examination, and a radiological examination by an expert were essential. Prognosis depended on (1) the amount of dust inhaled ; (2) the period of time over which this acted ; (3) the occurrence of infective processes, tuberculous or non-tuberculous. If the diagnosis could be made at such an early stage in the disease that sufficient silica had not been inhaled to produce irreparable damage, and so much damage has not been done as to produce disability, then it seemed that the disease could be arrested.

Dr. Middleton went on to discuss the industries in which silicosis occurred. The *Refractories Industry* employed 2000 to 3000 persons and was concerned with the manufacture of ganister and silica bricks. These bricks contained considerably over 90 per cent. of silica. A specialist medical board carried out *periodical medical examination of all the persons* employed. The *Sandstone Industry* represented the most widespread of all silicosis-producing industries, but the incidence of the disease was diminishing owing to the application of water and mechanical methods of dust suppression. The granite industry was allied to sandstone quarrying and dressing, but the subject was complicated because of the varying proportions of quartz, felspar, and mica present in the rock. As the result of an inquiry into the *Slate Industry* there appeared to be some evidence of the production of fibrosis of the lungs, but the occurrence of actual disability within the ordinary working lifetime of workers was not clearly shown. In the *Grinding of Metals* silicosis, and especially the combined disease of silicosis with tuberculosis, were at one time extremely prevalent. The sandstone wheel was being largely replaced by wheels of abrasives such as carborundum. Allied to the grinding of metals was the process of *Sand-blasting* of metals and the etching of glass. This consisted in playing a jet of sand under high pressure against a metal or glass surface to produce certain effects. The process was becoming more extensively used, and it was a matter for serious consideration whether a substitute such as iron or steel grit could not be used to replace the siliceous grit as the abrading material. In *Pottery Manufacture*, both in the manufacture of earthenware and of china, Dr. Middleton suggested that "potter's asthma" was due to dust containing ground flint. Ground silica was used in many industries; in the crushing and grinding of silica and in the industries in which ground silica was used silicosis sometimes of an acute type occurred. The evolution of dust in these industries was controlled by the use of mechanical methods of handling, enclosure of machinery, and the use of localised exhaust draught. *Tin Mining* in Cornwall had a high mortality-rate from tuberculosis, and it was shown that this was associated with silicosis. Drilling of the highly siliceous rock in which the tin ore occurred was now done through hollow steel with a water feed. Silicosis also occurred in *Coal-miners* employed on hard headings. It would appear that once enough silica had been inhaled to produce the nucleus of fibrosis, the resulting inhalation of coal dust into a lung in which the lymphatic drainage had been disorganised increased the fibrosis and produced disability.

Dr. Middleton concluded by describing the methods for determining the concentration of dust in the atmosphere by the gravimetric method and the numerical or counting method, but pointed out that there was no criterion of air dustiness which could safely be regarded as indicating freedom from risk of producing the disease.

Dr. P. HEFFERNAN (Tuberculosis Officer, Derbyshire) read a paper on the biophysics of silica and the ætiology of silicosis. Silicosis, he concluded, was the result of the local action of hydrated silica upon the pulmonary tissue. This action was of a physicochemical nature, and the speed of its development depended upon the rapidity with which fresh silica hydrosol was brought into contact with pulmonary tissues. Substances such as alkalis which favoured the formation of silica hydrosol from silica when added to silica dust accelerated the development of silicosis. Substances such as carbon, coal dust, or clays which retarded or prevented the formation of hydrosol from silica, or which coagulated the hydrosol when formed, retarded or prevented silicosis. Silica was a normal constituent of plant and animal cells and had a place in therapeutics comparable to that of lime.

Dr. WATKINS PITCHFORD (South Africa) spoke on siliceous dust in gold mining and uttered a warning about wet operations; siliceous mud, he said, was potentially siliceous dust. The noxiousness of siliceous dust was due to blocking of the lymph channels of the lung which allowed tuberculosis to develop.

Dr. R. E. LANE (Manchester) read a paper on the lead dust hazard. He showed that in industrial practice by far the most important portal of entry for lead was the respiratory tract. He spoke of the storage battery industry and of the types of lead dust met with in that industry. He emphasised the fact that normal healthy people both excreted lead in the urine in measurable quantities and showed minor degrees of punctate basophilia. In a research carried out on groups of lead workers in various departments he had found a definite relationship between the Pb. in the atmosphere, the Pb. excreted in the urine, and the punctate basophilia count; the basophilia could be used in estimating the danger arising from a lead process. He supported the findings of Sellars that all lead workers have a normal punctate basophilia, and that its mere presence cannot be taken as a proof of lead poisoning. It was, however, a delicate index of the degree of absorption, and as such of great value in anticipating trouble.

INDUSTRIAL TUMOURS OF THE BLADDER.

Dr. T. H. WIGNALL (Manchester) opened a discussion on the incidence of disease of the bladder in workers in certain chemicals. Certain chemical agents, he said, were known to cause forms of acute dermatitis and conjunctivitis, or bronchial and nasal troubles; others (for example, aniline) by absorption, ingestion, or inhalation, produced pigmentation, visible on face, hands, and ears, as well as general bodily weakness, dyspnœa, and possibly blood in the urine, owing to the production of methæmoglobin in the blood. Such cases, seen early and treated, recovered health, and he had not heard of any subsequent growths from acute illnesses of this type. Men working on α-naphthylamine for some years reported a frequent desire to micturate with strangury and blood in the urine. Cystoscopic examination revealed a neoplasm at the ureteric orifice in the bladder.

Mr. J. B. MACALPINE (Manchester) showed lantern slides and pathological specimens of carcinoma and papilloma of the bladder in aniline workers, many of whom were sent to him by Dr. Wignall. The growth in these workers would appear to be more malignant than similar growth in the general population.

Dr. ARCHIBALD LEITCH (London) spoke on experimental work with aniline dye-products. He had had no neoplastic response to any particular substance in mice, and suggested that the final carcinogenic agent was an end-product actually produced in the bladder itself.

Prof. J. M. STEWART (Leeds) suggested that inhalation of aniline dust rather than ingestion was the cause of the urinary troubles.

Dr. VERNON DAVIES, M.P., asked if anyone could give a definite opinion as to whether synthetic dyes did cause carcinoma of the urinary tract.

The PRESIDENT said that without doubt these tumours were far more prevalent among synthetic dye workers than in the general population, but no particular substance at the present moment could be blamed.

Dr. DONALD CAMPBELL (St. Helens) read a paper on the silicotic lung, in which he discussed the early diagnosis and differential diagnosis of the various fibroses of the lung, the importance of finding silica in the sputum, and of radiograms taken by an expert.

Dr. L. CAROZZI (Geneva) spoke on the human aspect of industrial diseases and accidents, and the need of utilising to the full the result of scientific investigation in other fields: physiology, pathology, and biochemistry. He dealt with idiosyncrasies in absorption and elimination in certain industrial skin diseases and industrial cancer, and stressed the necessity of constant medical examination of all workers, not only the sick but those in good health.

Mr. L. WARD (Engineering Inspector of Factories) gave a lantern demonstration of methods of prevention of industrial dusts.

The PRESIDENT illustrated the various processes of the cotton industry by lantern slides, and pointed out the dangers to health during each process.

Dr. E. S. BURT HAMILTON (Manchester) read a paper dealing with skin and mucous membrane lesions in chrome and arsenic workers.

In the pathological museum there was a large display of specimens, photographs, and charts contributed by Sir Thomas Legge, Prof. Stewart, Dr. Heffernan, Dr. Lane, Dr. S. A. Henry, Dr. C. C. Twort, Dr. Middleton, Dr. Cooke, and Dr. R. Prosser White.

SECTION OF ORTHOPÆDICS.

SCOLIOSIS.

Opening Address.

Sir ROBERT JONES presiding, a discussion on scoliosis was opened by Mr. D. MCCRAE AITKEN (London), who introduced a cinematograph film illustrating his methods and results. He pointed out that scoliosis was one of the earliest, as it was still one of the most difficult, problems of orthopædic surgery, and said that the observations of the early writers were as accurate and practically as valuable as those of to-day. It was the principles, not the details of treatment that mattered. He traced briefly the evolution of his own methods of treatment, wherein he had tried to apply to the spinal joints the principles laid down by Sir Robert Jones for other joints—i.e., continuous retention of the correct position while recovery of muscular function was taking place. His conception of these principles had been somewhat modified by the experiments of Sherrington and Magnus, which showed the importance of the inhibitory reflex, and that contractures, such as those of scoliosis, were often due as much to active shortening of muscle as to fibrosis. The postural reflex was largely a new name for the phenomenon long known to psychologists as the "automatic reflex," which played a large part in the training of athletes. Haglund, in using his short plaster jacket to tilt the lumbar region, had been one of the first to harness the postural reflexes to correction of the deformity. Mr. Aitken had found a modification of the Abbott type of jacket the most effective, because of its flexion of the spine to correct what he called the "squint lordosis," its pressure on the prominent ribs altering their habitual excursion into a more favourable one, and its power to deviate the patient's weight on to the leg opposite to the one he habitually used. This last point was important, and the speaker demonstrated that the side of the chest on the same side as the leg taking most weight was the one which expanded most, both with quiet and forced respiration—a phenomenon used by rowers for turning a boat, to do which they merely pressed harder on one foot.

An admirable film, produced by the Stoll Co., illustrated the points referred to by Mr. Aitken, especially the unequal breathing on the two sides of the chest. It also demonstrated each stage in his application of the modified Abbott jacket, and showed the patients standing and walking after the treatment. Without the previous photographs it would have been hard to believe how severe the initial deformity had been. With good team work, Mr. Aitken stated he could apply one of these jackets in half an hour. Correction was best maintained, he said, if the patients were taught only simple exercises for use in their own homes, not being allowed to depend on the atmosphere of the gymnasium. Besides the important exercise of sitting with pressure on the foot of the suitable side and standing on that leg, he strongly recommended the recumbent breathing and posture exercises of Goldthwait, of Boston, of which Miss Forrester-Brown had been the chief exponent in this country.

Discussion.

Mr. A. BLUNDELL BANKART (London), while congratulating Mr. Aitken on his results, expressed the conviction that even better ones would ultimately be attained if research continued. He thought scoliosis was essentially a contracture of a compound joint and that correction of the mechanical defect should precede education of the muscles. For this purpose he still advocated traction, for he did not believe effective pressure could be brought to bear on the spine through the ribs. Abbott's method only achieved a high degree of compensation, not actual correction of the defect, and this was disappointing. Scoliosis was a growth defect, comparable to club-foot and equally difficult to correct permanently. He suggested that there might be possibilities in skeletal traction.

Miss M. FORRESTER-BROWN (Bath) analysed the treatment of 65 cases, most of which were old neglected ones coming too late for correction but still amenable to great improvement in the general body balance and health. Only five had had correction in plaster jackets, and this had been applied by a modification of Galeazzi's method with the patient standing with the spine flexed. The shoulders and pelvis were included in independent parts and then joined together, while an attempt was made to correct the rotation deformity. A number of cases had got considerable gradual correction by sleeping for years on a plaster bed of Jansen's type. More than half the cases had required braces to support the spine, and in the manufacture of these the speaker emphasised the necessity of having the plaster mould made by an expert, while the positive model on which the jacket was to be built must be modified by, or under the eyes of, the surgeon. To hand the patient over to an instrument-maker without further surgical guidance was very unsatisfactory. In regard to the upper thoracic and cervical curves, which Mr. Aitken regarded as desperate, Miss Forrester-Brown had found that improvement of balance resulted from Elmslie's method of keeping the head a little suspended when the patient was seated during lessons. This helped the postural re-education. Although one might hope to prevent the majority of these severe cases by early diagnosis and treatment, some of the rickety and paralytic ones developed very insidiously, and parents were extraordinarily unobservant. Congenital cases were tedious to treat and the condition was apt to occur in poor homes, where they would be neglected.

Mr. P. B. ROTH (London) disagreed with Mr. Aitken's assumptions, saying that scoliosis was primarily a bone disease with no muscle defect, and that wedge-shaped vertebræ could not be straightened again with intermittent pressure from bent ribs. He thought that the best results were got from muscle-training in a gymnasium.

Mr. AITKEN, in his reply, said that nobody claimed to undo the wedging of the vertebræ, but only to mask it by improved body balance. He added that his plaster jackets did not interfere with school life, and the children played hockey in them.

Torticollis.

Mr. WHITCHURCH HOWELL (London) then read a paper on the treatment of torticollis. He advised subcutaneous tenotomy, done with very special precautions and followed by immediate fixation in the over-corrected position in plaster-of-Paris, which must include the whole chest and bear well on the mastoids and lower jaw. He quoted 20 successful cases out of 21 and showed slides of two excellent results.

A discussion followed in which the speakers were: Mr. R. OLLERENSHAW (Manchester), Mr. ROTH, Dr. WHITE (Norwich), Mr. AITKEN, and Miss G. HERZFELD (Edinburgh). Most of these, except Mr. Roth, deprecated the subcutaneous method as dangerous, except in the hands of someone of special experience such as the reader of the paper. They also considered it likely to be ineffective, because the fibrosis was seldom restricted to the sterno-mastoid muscle, usually involving not only its sheath but all the layers of deep fascia, often the arterial sheath itself, so that radical cure demanded a wide and careful dissection. They did not regard plaster fixation as necessary after the thorough operation, nor did they find a carefully placed skin scar to be conspicuous or troublesome.

CHELTENHAM GENERAL HOSPITAL.—This institution has been enlarged by the addition of 28 beds, a new out-patients' department, and an extension of the nurses' home. The work has cost £32,000.

ENLARGEMENT OF WAKEFIELD CLAYTON HOSPITAL. Mr. S. Canning Childs, of Camden, New Jersey, U.S.A., who last year gave a new out-patients' department to this hospital, is now presenting it with a new women's ward, which will have 48 beds, and will cost £30,000.

Reviews and Notices of Books.

STONE AND CALCULOUS DISEASE OF THE URINARY ORGANS.

By T. SWIFT JOLY, F.R.C.S., Surgeon to St. Peter's Hospital. London: William Heinemann, Ltd. 1929. Pp. 508. 45*s.*

THE author has presented us with a work that will surely be found on bookshelves abroad as well as at home, for great changes have taken place in this special branch of surgery during 20 years. Genito-urinary surgery, and particularly that branch which concerns the treatment of stone, has been revolutionised by the introduction of radiography and cystoscopy. The era of the exploratory operation for calculus has passed, the surgeon of to-day possessing a fairly exact knowledge of what he will find before he makes his preliminary incision. But, as Mr. Swift Joly points out in his preface, there exists yet another reason for bringing our knowledge of lithiasis up to date. Methods of diagnosis and treatment have changed, but so also has the disease itself. In certain areas of Great Britain, such as Norfolk and the Fen district, vesical calculus was formerly common; now it is comparatively rare. This is true to a less degree of other localities, for throughout the country vesical calculi are becoming less common, whilst the frequency of renal lithiasis remains about the same. The age and class incidence of the disease have also altered, so that it is no longer a disease of childhood found amongst the poorer classes, but of middle and of old age, occurring without discrimination of class. The reasons for these changes are discussed by the author at length in his second chapter. Stone formation, he points out, is due to a failure of the urinary colloids to hold the more insoluble urinary salts in solution. The change in its incidence witnessed in the last 50 years may perhaps be correlated with a general improvement in our dietary. There are reasons for believing that the excretion of an excessive quantity of uric acid is part of a deficiency disease, whilst oxaluria is often associated with intestinal fermentation. The more rational and varied dietary of modern times has the effect of diminishing both of these predisposing causes of stone formation.

Chapter III. deals with the diagnosis and treatment of renal calculus. In discussing its surgery the author shows a marked preference for the L-shaped incision recommended by Mayo, which commences over the last rib at the outer border of the erector spinæ and then passes outwards parallel to and about 1 inch above the iliac crest. If additional room is required, he advocates dislocating the last rib upwards over the eleventh rather than excising it. Pyelotomy, in his opinion, should always be followed by suturing the pelvis. Leakage of urine favours infection of the kidney, and this in clean cases is a disastrous sequel. When subcapsular nephrectomy is undertaken, Mr. Joly urges that every effort should be made to remove the whole of the renal pelvis. This is best achieved by Albarran's method of exposing the renal pedicle through a vertical incision in the lower portion of the stripped back capsuli. If this is not done a very thick pedicle is tied off containing the whole of the renal pelvis. As these cases are invariably infected a persistent sinus almost inevitably follows.

Mr. Joly holds the view that, generally speaking, surgeons err on the side of being too conservative in their surgical attack on stone. In many cases in which a pyelotomy or nephrolithotomy has been performed much future trouble would have been avoided if nephrectomy had been substituted. The aim should be to deal in the most efficient way with sepsis, and a prompt nephrectomy or nephro-ureterectomy, by totally eradicating the diseased area, may save the opposite side from subsequent trouble. In dealing with impacted ureteric calculi non-operative measures should only be attempted when the stone is lodged in the lower portion of the ureter. Even then the surgeon should be prepared to do an open operation after one failure to obtain expulsion by other means. The work concludes with adequate chapters on calculous anuria, vesical, prostatic, and urethral calculi. At the end of each chapter a table of references gives an indication of the author's extensive acquaintance with the literature of calculus, and at the beginning of the book is an entertaining historical sketch which takes the reader from 7000 B.C. up to A.D. 1924. Although illustrated with less profusion than most of the works that come from the other side of the Atlantic, the plates and diagrams are adequate and of good quality. The text throughout is clear, and the treatment of the subject practicable. Mr. Joly may enjoy the satisfaction that comes from knowing that he has written a standard work on the subject he has made his own, and we predict that Joly on Stone will be as well known to urologists of the present generation as was Jacobson on Surgery to surgeons of the last.

PHARMACY.

Pharmaceutical Formulas. Vol. I. Tenth edition, entirely revised and rewritten by S. W. WOOLLEY and G. P. FORRESTER. London: The *Chemist and Druggist.* 1929. Pp. 1146. 15*s.*

THIS is the tenth edition of a valuable book of reference which has appeared at steady intervals for the last 30 years. The original design of the book remains—that is to say, that we have here a collection of formulas for old as well as new preparations, which not only pharmacists and others in the drug and allied trades require, but which a great many medical practitioners will find of practical value. The present edition has been entirely revised and rewritten by Mr. S. W. Woolley, a former editor of the *Chemist and Druggist*, and Mr. G. P. Forrester, who now occupies that post; and their emendations have been directed towards the satisfaction of fresh demands, and recording progress in the art of compounding. As the authors point out in their preface, great advances have been made throughout the domains of pharmacy within recent years, coincident in many directions with advances in medicine, consequently many therapeutic agents have been added to materia medica, and improvements as well as innovations introduced in the manufacture of pharmaceutical preparations.

The volume is made up of selected formulas from the British, United States, and other pharmacopœias, together with non-official formulas from various sources, including numerous descriptions of practical methods employed in the manufacture of pharmaceutical preparations and other information of use to pharmacists and drug-producing firms, and of increasing interest to doctors. The pages comprise also a selection of formulas for "known admitted and approved remedies" from former editions and from the *Chemist and Druggist* diaries. The practical nature of the book is reflected in the fact that its contents in many instances represent inquiries received by the editor of the *Chemist and Druggist* from chemists and manufacturers at home and abroad, and seeking particulars regarding recent medicaments, and preparations included in hospital or foreign pharmacopœias. Many of these questions have had reference to formulas designated by the name of their authors or originators, and, as we can quite understand, the editor of our contemporary has had great difficulty in some instances in rendering correct replies. The employment of such titles for a prescription as "Stokes' Expectorant," "Franklin's Formula," "Griffith's Green Mixture," "Heberden's Ink," and so forth, is of historic interest, but from a scientific point of view the sooner these nicknames disappear the better.

A second volume, now in course of preparation, will contain formulas which cannot properly be classed as pharmaceutical, such as recipes and processes for the preparation of a wide range of articles which contribute to the interests of modern life. This promises to be very interesting, and, judging from the analogy of

"Cooley," of high practical value. For it is a little astonishing to find how many articles of daily use are mysteries, as far as their composition is concerned, to those who are familiar with their frequent application.

Physics for Students of Pharmacy. By C. J. SMITH, Ph.D. London: Edward Arnold and Co. 1929. Pp. 287. 9*s.*

THERE are to-day so many books, small, middle-sized, and large, compiled to meet the needs of the commencing science student, that a first impression on seeing yet another elementary text-book of physics necessarily is that there can hardly be room for it. Dr. Smith, however, has arguments to the contrary. He has thought that the syllabus of the Pharmaceutical Society of Great Britain invited a manual to meet the needs of those who would comply with the professional tests, and he has accordingly furnished some excellently clear instruction, in which the brevity of the first sections is accounted for by the fact that he has expected his readers to have done a course of matriculation physics at some previous period. Epitomising has been the author's aim, but always with the endeavour to make definitions clear, and his objects are accomplished. The section on light is done in more detail than is usually the case in books of this range, and in the section on magnetism and electricity there are many paragraphs which clear up difficulties in a manner which should appeal to the often puzzled student. For example, the chapter on magnetic measurements and that on electrical resistance will be really useful to many reading physics with whatever aim, for undoubtedly the phenomena described are, even when laboratory work goes hand in hand with reading, obscure to the early worker. This is a good little text-book.

SPECIAL CYTOLOGY.
Edited by EDMUND V. COWDRY, Ph.D., the Rockefeller Institute for Medical Research. New York: Paul B. Hoeber; London: Humphrey Milford, Oxford University Press. 1928. 2 vols. Pp. 1348. 693 illustrations. 94*s.* 6*d.*
Handbook of Microscopical Technique. Edited by C. E. McCLUNG, Ph.D., Professor of Zoology and Director of Zoological Laboratory, University of Pennsylvania. Same publishers. 1929. Pp. 495. 36*s.*

THE work on Special Cytology is supplementary to the earlier volume on General Cytology published under the same editorship by the University of Chicago Press in 1924, and the series is completed by the volume on technique under the general editorship of Prof. C. E. McClung. The custom of coöperative publications is more and more coming into fashion, and it is one for which we have nothing but praise. It is still possible for a single individual to write a biological or medical text book of a general or elementary nature, but a more ambitious work on any particular subject demands a breadth of knowledge and a grip of detail such as few men possess. A book written by many authors may lack cohesion and unity, and that imprint of personality which made many of the older text books really great. But it has the overwhelming advantage that each section is written by a specialist who has a first-hand knowledge of his subject, and is content to deal with that subject only.

No less than thirty-five authors contribute to the two volumes on Special Cytology, and differentiation is carried to such length that, for example, in the chapters dealing with the nervous system one contributor is responsible for the internal architecture of the nerve cell, another for the general relation of histological character to function in mammalian neurons, another for the sympathetic nerve cell, another for the neuroglia and microglia, and another for the cytology of the cerebro spinal pathway. Under these circumstances a single reviewer may be excused if he refrains from any attempt at detailed criticism and restricts himself to a general survey.

These volumes should be invaluable, not only to cytologists, but to workers on biology and medicine. It is all the more to be regretted, therefore, that it is necessary to publish them at a price which must be prohibitive to many laboratory workers. There are, it is true, a large number of illustrations, but many of them are copied from other works, and there are only two coloured plates. And while most of the illustrations are good, some are quite unworthy. For example, the 41 figures of the myeloblast, following p. 396, are of little or no value, though no doubt the authors' original coloured drawings, of which they are photographs, adequately fulfilled their purpose. Figs. 92 and 93 stand out as glaringly bad and old-fashioned, and some of the figures illustrating the chapter on the thyroid are unpardonable in a work of this class.

Perhaps the most striking impression the book makes is that cytology is a really vital and progressive science; it rests, of course, on an anatomical basis, but its trend is essentially physiological. Then, again, the breadth and ramifications of cytology are revealed in such a manner as to make it abundantly clear that it is very far from being, as many believe, a narrow and academic subject; and this, in spite of the restrictions which considerations of space made necessary. Attention is directed chiefly to those cells which make up the human body; animal forms below the mammalia are not specifically dealt with. Again, the work contains but little embryology, but on the other hand pathology is freely drawn upon when it throws light, as it so often does, on the normal. And each chapter contains an abundant bibliography, the better for being selected.

While not designed primarily for the medical worker, Prof. McClung's contribution to the series should prove valuable to those engaged in histological research. It differs from most handbooks of its kind in that attention is given to the principles underlying the making of microscopical preparations. The sections devoted to the examination of fresh material and to microdissection and injection are admirable, and the selection of typical staining methods judicious. Dr. Robert Chambers here deals with a subject which he has made peculiarly his own, and supplies excellent figures to illustrate the technique employed. In certain respects the work is not so profound and detailed as might have been expected. The section on fixation and fixatives is elementary and not particularly helpful; and in the troublesome subject of decalcification, the pathological histologist will find little assistance. A relatively large amount of space is devoted to the histological study of the blood, and in this section are included procedures, such as methods of determining hæmoglobin percentage, which scarcely come into the scope of a manual of microscopic technique. On the whole, however, this is one of the most valuable books of its kind to be published for many years; it should run into many editions. As a worker in histology grows more experienced, he will find that by following the principles set out in this handbook he will obtain such a grasp of microscopical technique that he can adapt it to his special needs, instead of planning his work on conventional lines.

NERVOUS AND MENTAL DISEASES FOR NURSES.
By IRVING J. SANDS, M.D., Associate in Neurology, Columbia University, New York. London and Philadelphia: W. B. Saunders Company, Ltd. Pp. 239. Illustrated. 8*s.*

THIS small book is well-planned and readable, and though intended for nurses will be found useful by students and those starting on mental hospital work as junior medical officers. The chapter on medical psychology is particularly good, though one may question whether manipulative and play instincts should be considered as instincts or more correctly as elaborations of instincts. The description of conditioned reflexes and conditioned emotional reactions and their relative importance in training and in the prevention of illness is informative. The account of the neurotic personality is hardly adequate, the hysteric type alone being described. The description of encephalitis lethargica and its after-effect is good, but it is not made clear that the anti-social reactions occur most commonly when the acute disease attacks children and adolescents. The author is unduly optimistic as to the prevention of general paralysis of the insane by early treatment of syphilis.

Dementia præcox is here classed among psychogenic disorders, the alleged endocrine and neurological changes being ignored. Among the excellent suggestions for treatment is one of "beauty parlours" to train patients in care of their personal appearance, though we hardly expect to see these instituted in our own hospitals. More space might usefully be given to general paralysis, while the sections on other organic psychoses could be curtailed, and also the elaboration of differently caused toxic psychoses. Drug addiction may be regarded as an expression of compulsion neurosis in many cases, but this is not suggested in the otherwise adequate account given of this. If the book is to be widely used in England a section as to our recognised means of mechanical restraint, which differ from those described, and the legal precautions in using them and seclusion, should be added; and modes of certification and limitations in treatment of patients as voluntary boarders also deserve some space, though, perhaps, not much.

For nurses, the chapter on special nursing procedures at the end should be supplemented by another on general nursing for mental and nervous patients, giving information about emergencies such as suicidal attempts, poisoning, and special precautions as to windows and fires. At present these instructions and also directions about feeding, prevention of bedsores, and care of the bladder are scattered amidst the descriptions of special types of illness and unnecessarily repeated. More emphasis should be laid on care as to feeding in general paralysis, and the importance in epilepsy of observing carefully not only the actual fits but prodromal signs and epileptic equivalents.

The book, however, gives a sound survey of the essential features of mental disorders and of the efforts being made to relieve and restore the afflicted to health.

SOME PRINCIPLES OF MINOR SURGERY.

By ZACHARY COPE, M.S., M.D. Lond., F.R.C.S. Eng., Surgeon to St. Mary's Hospital and to the Bolingbroke Hospital. London: Humphrey Milford, Oxford University Press. 1929. Pp. 159. 10*s*. 6*d*.

THE author does not attempt to cover the wide field of minor surgery as a whole, but limits himself to certain fundamental principles, which while elementary are yet of everyday importance. In the first chapter on the use and abuse of antiseptics, the lessons of the war are well summarised. In the consideration given to Dakin's solution, however, we could find no mention of its all-important property of dissolving dead protein material, although the value of clearing a wound of all dead material as a means of sterilising it is fully recognised. Maggots, those admirable scavengers to whom many wounded soldiers owe their lives, have a similar action. In the chapter on the treatment of acute inflammation, admirable on the whole, the author shows undue optimism about the benefit to be expected from vaccines. We find no mention of mercurochrome in this section. The superposed pictures in the chapter on infections in the hand make the text easy to follow. Much industrial disability follows such infections, and is far too often increased by ill-conceived treatment; this chapter is thus of great value to the practitioner. In the section on common sprains more stress might be put on the place of manipulation in treatment. The teaching of minor surgery to medical students is too often left in very junior hands, and the practitioner may never have had the opportunity of studying the principles on which routine procedures are based. These Mr. Cope has presented in a concise and practical form.

LE SYNDROME ÉPILEPSIE.

By O. CROUZON, Médecin de la Salpêtrière. Paris: Gaston Doin et Cie. 1929. Pp. 264. Fr.55.

DR. Crouzon's volume on epilepsy is erudite and comprehensive, yet its perusal leaves a slight sense of disappointment. Filled with an amazing number of facts of observation culled from all kinds of sources, ancient and modern, it seems to fail in the personal element; the reader is neither provided with critical summaries by the author nor apparently with any expression of his own views, based on what must be a wide clinical experience. The ground covered includes everything from the epileptic aura to the social reactions of the patient; the arrangement of material and lucidity of description leave nothing to be desired. But through this literary labyrinth we need guidance; we want the salient features emphasised and the non-essentials put on one side, and we are left to do this for ourselves. A minor note of remonstrance is called for; while numerous references are given a locus in journal or society proceedings, very many more are restricted to the writer's name, and some of these are clearly of importance.

L'ENCÉPHALITE ÉPIDÉMIQUE: SES ORIGINES:

Les 64 premières observations connues. By Dr. RÉNÉ CRUCHET, Professor in the Faculty of Medicine of Bordeaux. Paris: Gaston Doin et Cie. 1929. Pp. 133. Fr.15.

IN the spring of 1917 Dr. Réné Cruchet communicated to the Medical Society of the Paris Hospitals a paper describing some 40 cases of subacute encephalomyelitis which had been under his observation from towards the end of 1915 to the earlier months of 1916, almost entirely among military subjects, and again later in 1916–17 in another region. This little volume contains a detailed account of the cases and a reasoned claim that they belong to the class now commonly termed epidemic or lethargic encephalitis; the argument is perhaps supported by the fact that one of them, seen in December, 1916, later developed the bradykinetic syndrome and is declared to be one of parkinsonism. The remarkable clinical variety and heterogeneousness of the pictures presented by these cases are well illustrated; the author saw the condition evolve in mental, meningeal, convulsive, choreic, hemiplegia, cerebellar, pontine, spinal, and polyneuritic form. Handicapped as he was by the circumstances of the time, it is remarkable that he was able to make as careful an investigation as he did, even if details of a confirmatory kind are sometimes lacking.

Whether this encephalomyelitis of 1915-16-17 was and is a "new" disease is another question.

SINUS THROMBOPHLEBITIS.

By ALFRED BRAUN, M.D., Attending Otolaryngologist, Hospital for Joint Diseases, New York. With 111 illustrations. London: Humphrey Milford, Oxford University Press. 1929. Pp. 269. £2 12*s*. 6*d*.

A beautifully illustrated monograph on the inflammatory affections of the venous sinuses in the dura has for its central thesis the tracing of general sepsis of otitic origin. Sometimes glaringly obvious, at others slight, hidden and elusive, otitis is, mainly for anatomical reasons, a sinister cranial mischief-maker out of proportion to its degree or extent. Accordingly, the reader is introduced, in a section occupying rather less than one half of the book, to a complete anatomical description of vascular mechanisms in connexion with the ear and their immediate and distant relationships. The book is essentially an atlas, for the drawings and diagrams are on a generous scale and the text does little more than comment on their significant features. The physiology of the dural venous sinuses, and the way in which the venous blood-flow is protected from the aspiratory effects of inspiration is elucidated. Next in order are treated the etiology and pathology of sinus phlebitis, and its semiology and diagnosis; an excellent résumé of the most modern therapeutic technique is furnished in a final chapter of some 60 pages. Among useful practical matter is the description of the Queckenstedt phenomenon as adopted for diagnosis of unilateral sinus thrombosis; the account of the neural complications of the condition is in some respects inadequate (for instance, that of the syndrome of the superior longitudinal sinus), and the data (clinical and spinal fluid) for differentiation from meningitis. The bibliographical references are largely confined to German and American sources.

TRIAL OF JEAN PIERRE VAQUIER.

Edited by R. H. BLUNDELL and R. E. SEATON, Barristers-at-law. Notable British Trials. Edinburgh and London: Wm. Hodge and Co. 1929. Pp. 208. 10*s.* 6*d.*

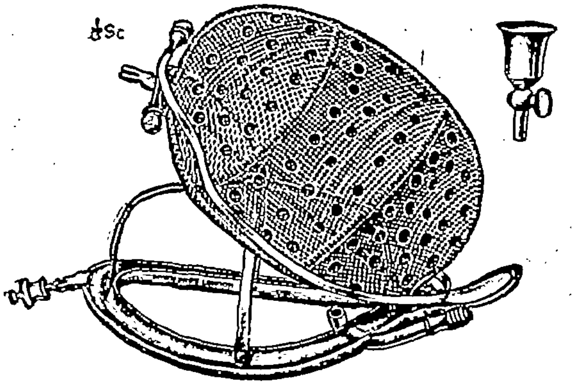
THE evidence upon a charge of poisoning, "of all forms of death the most detestable," is usually circumstantial, not direct. In Vaquier's case it was overwhelming. He became intimate with an Englishwoman, Mrs. Jones, who came to Biarritz for a holiday early in 1924. He followed her home to the Blue Anchor Hotel, Byfleet, which she managed with her husband. Mr. Jones used to take bromo salts (kept in a bottle on the bar-parlour mantelpiece) on the morning after his carouses. One Saturday morning he took his usual dose, complained of its bitter taste, went into convulsions, and died. His medical attendant, Dr. F. C. Carle, diagnosed recent strychnine poisoning, and with great promptness took possession of the bottle of salts, glass and spoon used by the dead man; he also discovered some spilt crystals on the bar-parlour floor. All these articles were eventually found to contain traces of strychnine, and the evidence of Sir Bernard Spilsbury and Mr. John Webster left no doubt of the cause of death. Vaquier, who had been early in the bar-parlour that day, had bought strychnine in London "for wireless experiments"; while in prison he revealed the hiding-place of a further supply of the poison in a toolshed in the hotel garden. He tried to implicate a mysterious third party, and the main feature of his defence was a vigorous attack on the credibility of Mrs. Jones; but there was no doubt of the verdict, and he was hanged in August, only a few months after he first met her.

The editors' introduction is workmanlike and wholly satisfactory; there is no straining after dramatic effect. The main medico-legal interest lies in the comparison of the knowledge, confidence, and precision of modern experts with that of the scientific witnesses in a case of strychnine poisoning such as the Rugeley trial some 70 years earlier. Fitzjames Stephen, who was present during most of the latter trial, gave a contemporary exposition of the effect of the expert evidence against Palmer in his "General View of the Criminal Law of England," a book still well worth studying.

New Inventions.

ETHER INHALER.

THE ether inhaler here illustrated has for its basis the principle of a vapour space which is obtained by superimposing an outer wire gauze cage on a Schimmelbusch face-piece. The gauze is perforated at short intervals, and when in use is covered with one or two layers of lint held in position by a spring. The outer cage when clipped down holds the face-piece lint in position, and ether is introduced by a small funnel through the perforations in the gauze. A feed pipe is fixed near one end of the face-piece through which oxygen or oxygen and ether vapour can be introduced under the mask. The cage is so constructed that it can be completely removed, and the mask used as an ordinary Schimmelbusch by fixing a wire retaining-ring in its place. When in use anæsthesia can be maintained either by blowing a slow stream of oxygen through ether into the mask through the feed pipe, the proportions of ether and oxygen being ideally maintained by such an apparatus as Mennell's bottle and by-pass, or by gently dripping ether through the gauze by the funnel. In all cases it is advantageous to use oxygen while maintaining anæsthesia. By adding an extra layer of lint to the cage or by covering with a layer of gamgee the anæsthesia can be deepened at will.



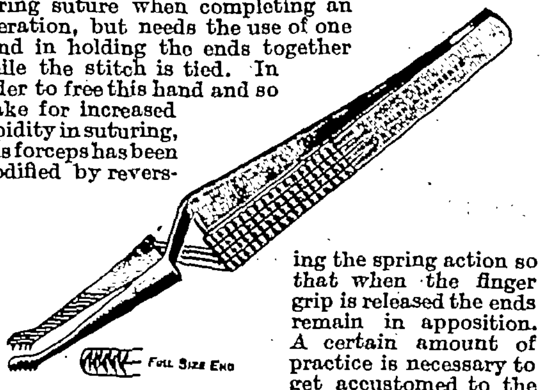
Among the advantages of this inhaler are ease and uniformity of anæsthesia, clear view of the face during anæsthesia, and economy in use.

I would like to thank Dr. Z. Mennell, senior visiting anæsthetist, and Dr. G. Edwards, senior resident anæsthetist, of St. Thomas's Hospital, for testing the inhaler and for their very helpful suggestions. The mask is made by Messrs. Down Bros., Ltd., St. Thomas's-street, London, S.E.

Bedford. G. A. METCALFE, M.B., B.Ch.

SKIN FORCEPS.

THE approximating forceps for the skin designed by the late Mr. C. P Childe, of Portsmouth, is of great assistance in avoiding the in-turning of skin edges during suture when completing an operation, but needs the use of one hand in holding the ends together while the stitch is tied. In order to free this hand and so make for increased rapidity in suturing, this forceps has been modified by reversing the spring action so that when the finger grip is released the ends remain in apposition. A certain amount of practice is necessary to get accustomed to the reversed action of the spring, but it will be found that the modified instrument does help in producing a neat and therefore quick-healing scar.



The instrument has been made for me by Messrs. Allen and Hanburys, of Wigmore-street, London.

A. W. HOLTHUSEN, M.B., B.S. Lond.

THE LANCET.

LONDON: SATURDAY, AUGUST 10, 1929.

THE BACTERIOPHAGE AND THE CURE OF DYSENTERY.

Ever since the dawn of the bacteriological era it has been the therapeutic ideal of all who have accepted the germ theory of disease to acquire some means whereby the specific micro-organisms might be destroyed or disarmed and the healthy tissues left unaffected. Innumerable agents have been on their trial, from the crude antiseptics of early days, through the biological antibodies of a later period, to the modern chemotherapeutic stage. All along this steady course of trial and progress may be seen landmarks which indicate certain notable measures of success; some clear and towering, rising erect against the winds of controversy and the corroding influence of time—such as diphtheria antitoxin, the vaccine virus, and salvarsan; others more inchoate, denoting an area whose limits are not yet demarcated—such as the benzidine group of dyes to which the modern trypanosomicidal drugs belong. One agent stands unique amongst these varied bactericidal substances—the bacteriophage described by Twort and d'Herelle. It is unique because so little is known of its nature, whilst its effect in the body as a therapeutic agent is still disputed.

The view of this substance, which at our present stage of knowledge seems most rational, is to regard it as akin to the filterable viruses, and as such its study may well lead to important advances in our knowledge of the latter, since it is an agent easily detected and handled and readily submitted to all forms of experimentation. The actively destructive effect of the bacteriophage upon sensitive bacteria is indubitable, and can be readily observed both with the naked eye in mass cultures and under the microscope upon the individual organism. It would therefore seem, upon a priori grounds, that it should constitute an ideal agent for an attack upon micro-organisms in the body, and especially upon those which act upon the surface of the intestine and pullulate in the intestinal canal. In one respect only are inherent difficulties apparent. These lie in the circumstance that when complete destruction of the organisms is not effected, resistant strains of bacteria may develop, which present an interesting analogy to the drug-fast strains of protozoa which have been such a constant source of difficulty in the chemotherapeusis of protozoal infections. What is the exact factor determining the resistance which bacteria may develop against a given phage is at present unknown. It has been widely assumed, and with a good deal of supporting evidence, that it represents a variation in the antigenic constitution of the organisms, in the technical language of the bacteriologist a variation in the "rough" direction. This variation can be brought about by other environmental conditions and may in this instance be produced by the bacteriophage. This is the view adopted in general by Hadley.[1] However, L. M. Burnett[2] in a recent paper, has adduced evidence that in the acquisition of resistance no observable serological changes in constitution may take place, the only notable effect being the loss of the resistant bacteria of the ability to adsorb the specific phage in question.

With regard to the clinical problems, which are of more general interest, we publish on p. 273 a contribution by Dr. A. Compton to the study of the therapeutic value of the bacteriophage in bacillary dysentery. About this value conflicting reports have been issued, many of which have been noticed in our columns from time to time. Of all diseases those of the intestinal group should be most amenable to treatment by this means, and it may be recalled that it was in connexion with dysentery that d'Herelle made his initial claims for the practical therapeutic use of the bacteriophage. In general, these claims have been not confirmed, although in a recent communication[3] d'Herelle announces that "the method has been applied in tens of thousands of cases of bacillary dysentery and recovery always took place in 24 hours." We are not aware that the collected details of such cases have ever been published. Dr. Compton bases his report upon 66 cases of Egyptian dysentery which had been diagnosed "cytologically" as of bacillary origin. The type of infection is stated to have been predominantly of the Hiss variety, and the bacteriophage in use a polyvalent strain including one variety of d'Herelle's own isolation and apparently of high potency. The cases were not observed directly, but were under the control of outside doctors. If we examine the reported results initially, we find a maximum beneficial effect to have been obtained in 35 out of 66—i.e., just over 50 per cent. The criterion adopted is the diminution in the number of stools, which fell to 2 to 3 per day on the second day of treatment, and (presumably) uninterrupted recovery thereafter. The ordinary saline treatment was carried on coincidently with the specific measures. Such a result, taken at its face value, appears to be excellent, but it is a constantly recurring lesson in medicine that face value results are not always safe guides to the value of medicaments. Only rigidly controlled parallel series of treated and non-treated cases will give information of real and lasting value. Dysentery is by no means always a serious and progressive malady. Anyone who has had experience of a considerable epidemic of it knows that in many cases the infection may be self-limiting and recovery may occur without any specific treatment. It is not suggested that a large proportion of Dr. Compton's treated cases are likely to have been in this category, but the possibility represents an interfering factor, whose extent it is not easy to estimate. The treatment did not appear to affect the well-known influence of age as a prognostic factor in this disease. Phage or no phage, the younger the patient the greater the mortality. There is still lacking a sufficient and clearly cut investigation of this important question which will enable us to judge of the value of the bacteriophage in dysentery. The usual criticism of negative results, that the strain of phage was not of maximum virulence, is a weighty one which cannot be disregarded. Since the evidence of the value of this treatment is anyhow not so convincing as to make it inhuman to withhold it from any sufferer, it would be a real service to therapeutics if those who, like Dr. Compton, have access to an unlimited number of cases of bacillary dysentery would treat alternate cases with the bacteriophage and the others by any one of the approval methods, giving in each case a detailed bacteriological examination before and during treatment and chronicalling the clinical course. Only by such an investigation can the question be solved which ten years of scattered observations and uncontrolled reports, suggestive though they may be, have still left unanswered.

THE EPIDEMIOLOGY OF MEASLES.

SINCE cholera, small-pox, and virulent scarlet fever became negligible factors of exanthematic child mortality, measles has been a prime object of concern to the health departments, sharing precedence with whooping-cough and diphtheria. The epidemiologist has been preoccupied by its curious manifestations for even longer. When a locality is hit by one of the periodical waves of measles the child population is always extensively involved, and the evolution of each outbreak is not influenced by any counter measures which have hitherto been tried. The illuminating studies of mass infection and immunity which have resulted from bacteriological and immunological discoveries in diphtheria and scarlet fever have left the epidemiology of measles no further advanced. Almost the only method of investigation open to us in measles is the statistical one which, though it can achieve little unaided, can be invoked to confirm or refute laws framed on other evidence. We welcome, therefore, an attempt to explain the well-known phenomena of the epidemicity of measles by the theories of "latent epidemisation" and "latent immunisation"[1] made in a recent study by Dr. PERCY STOCKS and Miss MARY KARN.[2] To this end a most elaborate procedure has been adopted. The detailed records of all cases of measles notified in the metropolitan borough of St. Pancras during three years from March, 1924, to March, 1927, have been studied, as well as the statistics of deaths and notifications since 1916. The living population at each age under 12 in St. Pancras at the beginning of the three years' period was estimated by applying the ascertained births and deaths to the census data, and the number of children at each age under 10 who could be regarded as definitely immune from recognised measles was ascertained from the statistics of notifications from 1916 to 1924. By laborious adjustment it was possible to estimate at any one time during the three years' period the separate numbers in two groups—viz., those who had already been familially exposed to measles during the period (the selected population), and those who had not (the residual population)—and to divide the former into those who manifested immunity after the lapse of varying periods of time and those who did not. Investigation of the true infectivity of the virus, as distinct from its apparent infecting power, and also the relation of this quality to different meteorological conditions, were attempted.

The conclusions arrived at are as follows: (1) The epidemic phenomena of measles are inexplicable if experience of an attack of recognisable measles is the only way of acquiring immunity; (2) a study of the incidence of measles at different times in the selected population, as compared with the residual population, shows that individuals in the former group acquire, without manifest sickness, a degree of immunity in excess of that exhibited in the latter and tending to diminish with the lapse of time—probably vanishing in most cases within two years; (3) this accounts for the observed fact that many children assumed to have no acquired immunity go through an epidemic without sickening, and it may explain the biennial periodicity of the disease; (4) the retardation of spread from the later foci of an outbreak, as compared with those at the onset, may also be explained by latent immunisation; (5) the *apparent* infectiousness of measles varies from a maximum at the onset of an epidemic, falling throughout its evolution to a minimum at the end, gradually increasing again in the course of the non-epidemic interval; (6) "all the changes noted in apparent infectiousness are explicable by immunity changes alone, excepting the *sudden* fluctuations, which must be attributed to changes in facility of transmission," such sudden fluctuations occurring mostly at the commencement of large epidemics; (7) the curve of the epidemic can be almost completely explained "by the concept of an active plus latent immunisation of the child *population on the one hand, and changes in facility* of transmission of the virus by droplet infection from cases or carriers to other persons coming in contact with them on the other;" the latter phenomenon being possibly related to certain atmospheric states.

It will be seen that Dr. STOCKS and his collaborator have succeeded in applying to the behaviour of measles the laws for which bacteriological and immunological support can be adduced in other communicable diseases. Confirmation of the investigation is not likely to be forthcoming at any near date because of the labour involved, the statistical skill required, and the paucity of data available. Incidentally it may be noted that an inquiry of this kind might have been even more fruitful in a more sparsely populated area, such as Renfrewshire, where measles was notifiable and carefully carded for more than 20 years, and where extra-domiciliary infection was proved to be much rarer in villages than in towns. A test that may be applied immediately, however, is the experience of practical workers in the field of the communicable diseases. Is there even circumstantial evidence of the carrier state or of anomalous forms of measles, comparable with that which can be adduced to support the theory of latent epidemisation and immunisation in other zymotics, whether of known or unknown origin? It must be confessed that there is very little. When inquiries are pressed they rarely fail to trace measles to another recognisable, if unrecognised, case. Only very occasionally does one see the crossing of a ward, for instance, by a child with coryza, Koplik's spots, and no more than a slight blotchiness behind the ears or down the side of the neck, in contrast with the experience in relation to diphtheria and scarlet fever. It is, of course, possible to argue that the signs of anomalous measles resemble so closely those of catarrh of any other origin that the infection is likely to escape diagnosis until a specific test is devised, but if this were so measles should be much less easily traceable than it is. If, then, latent infection occurs, it is without demonstrable association with modified forms of the disease. On the other hand, the general behaviour of epidemics of measles, noted by the late Dr. JOHN BROWNLEE fits well with the new hypothesis, as does the phenomenon of apparent non-infectiousness in hospital wards during inter-epidemic periods mentioned by the same observer. Dr. STOCKS and Miss KARN have produced what is in many respects the most valuable contribution to the study of measles which has appeared since BROWNLEE'S ingenious, if rather fanciful, work on the periodogram.

THE CORONER'S DISCRETION.

WHEN Parliament three years ago enacted that every coroner should be paid by salary instead of by fees, it was hinted that the fee system had been a possible inducement to coroners to multiply inquests. In introducing the Bill which effected the change, Lord CAVE expressed the opinion that the suggestion was unfounded. In any case the change in the law was welcome. The Chalmers Committee's report, issued in 1910, observed that a coroner had often more trouble over holding a preliminary inquiry than over the actual inquest; *if he satisfied himself that there* was no public ground for holding an inquest and thereby saved unnecessary pain and distress to relations of the deceased and expense to the community, it was rather unfair that he should, so to speak, be fined for his good conduct; "it is not right," added the report, "to put a coroner (and still less his officer) in the position of having a pecuniary motive for holding unnecessary inquests." The desired reform—in the Coroners (Amendment) Act of 1926—gave the coroner a statutory encouragement and authority to dispense with inquests. Already the critics are asking whether inquests are not now too few.

Statistics are here more than usually inconclusive. The latest available from the Home Office deal with the year 1927 and so cover only a few months of the operation of the Act of 1926. In 1927 there were 60,511 deaths reported to the coroner; 13,108 of these were deaths of lunatics and mental defectives in institutions. In only 345 of these institution cases was an inquest held, but, in view of the medical information no doubt available as to the condition of the patients, the small proportion of inquests is easily understood. Against the total of 60,511 deaths reported to the coroner in 1927 we have the figure of 32,430 inquests held. For what the comparison may be worth, we can look back at the figures a few years ago. For 1924, for example, the corresponding totals of deaths reported and inquests held were 58,062 and 31,705. In the past few years, it seems, the number of inquests has remained fairly stationary while the number of deaths reported has considerably increased. It would be most unsafe to dogmatise upon such material; local variations are *due to accident and to the varying exercise of the* individual coroner's discretion. The 1927 tables show that in one jurisdiction a coroner happened to hold an inquest in every case of death reported to him, while, in the same period, a coroner in another jurisdiction was content to hold only one inquest for every five such deaths. These differences are inevitable. They were noted by the Chalmers Committee in 1910 when it was found that in one part of London the percentage of inquests to deaths reported was 59 while in another it was 81. It has probably been the experience of many general practitioners that on occasions when they regarded an inquest as unnecessary an inquest was nevertheless held; conversely, when, so far as is within their power, they have indicated the desirability of clearing up some puzzling or suspicious symptom, the coroner has dispensed with a formal inquisition. The coroner's decision not to hold an inquest is an act of executive rather than judicial discretion; the exercise of such discretion, conducted in private rather than in public, may find critics; it can at least be hoped that there will be the maximum of agreement between the coroner and the medical practitioner. The 1926 Act and the 1927 Regulations, which the late Sir George Greenwood and his supporters thought so inadequate a protection against either foul play or premature burial, vastly improved the old method of reporting suspicious cases to the coroner. The new system, involving perfect confidence between coroner and practitioner, is on its trial. The public, puzzled by recent exhumations of bodies and reopenings of inquests for which neither coroner nor practitioner is in any way to blame, may feel vague misgivings as to the modern working of an ancient tribunal. If at any time it were disclosed in some sensational case that the coroner had neglected or undervalued the practitioner's warning, Parliament might be pressed to limit the discretion which it conceded in 1926.

Annotations.

"Ne quid nimis."

THE EXPERIMENTAL METHOD IN PSYCHOLOGY.

IT is the fate of any science which has one hand on the human heart and the other on the laboratory instrument to promise more than it can give in respect to the problem of mind. The extraordinary achievements of the scientific method in the field of physics and chemistry promised equally glittering prizes to those who entered the lists of psychology with stout hearts and sharp instruments. With the aid of physiology, psychology has now definitely emancipated itself from metaphysics, and has sought to adopt methods comparable to those used in the study of physiology of the special senses, where a local problem can be, to some extent, isolated. Where the reactions of the whole organism are involved, however, dealing with a problem in a circumscribed or local way becomes impossible. It is to this difficulty in experimental psychology that Mr. F. C. Bartlett *devoted his Presidential address, delivered in* Cape Town on July 26th to the Psychological Section of the British Association. He has endeavoured in a historical survey to show that such idols in the temple of psychology as G. T. Fechner and H. Ebbinghaus have in reality not served their science too well in stressing the great importance of the stimulus in the reactivity of the organism. In the study of pure sensory experience, if such experience can be divorced from all others, the relationship of stimulus, however simple to response, can be studied with the hope of realising simple dogmatic laws. But no sooner do the processes studied leave the field of simple sensibility and begin to involve more complex functions and the attitudes of the organism as a whole, than the qualifications limiting results grow alarmingly and the method exhibits its shortcomings. *In such complex "sets" the stimulus does not entirely* govern the response, but merely acts as a trigger mechanism setting free propensities and activating large psychological systems or attitudes. The fault lies in the attempt on the part of the experimental method to study the organism too much away from the context of ordinary biological situations. The nonsense syllable method for the study of memory and retentiveness is a convenient example. In most, if not in all living situations, the stimulus *is* but a fraction of a total system of vectors. Mr. Bartlett notes that the physiologist "rightly lays the chief emphasis upon the local response mechanism, and for obvious reasons shrinks from speculations about the central processes until he knows as much as can be learnt about the peripheral functions and their mode of operation." But since it is these central processes that are the primary concern of the psychologist, the latter can learn little by the study of the peripheral events and can safely leave them to the neurologist.

Strangely enough, as Mr. Bartlett acutely observes, the very protagonists of the experimental method are the persons most prone to commit the error of what may be called unbridled "a priorism" in claiming more for the method than it can with its limitations produce. The theory of Gestalten, the Spearman theory of two factors, Jaensch's deductions on character from his experiments on "Eidetic Images," and lastly the easy acceptance of the conditioned reflex as the new panacea, are examples of the dangers of attempting to stretch the experimental method to cover the whole field of the mental life. Behaviourism, and the conditioned reflex which has become the irreducible unit of this valuable experi*mental approach to behaviour, are illustrations of the* dangerous consequence of the absence of logical scrutiny at all stages in the development of a new approach. So far has the enthusiasm for the conditioned reflex gone that Pavlov himself speaks of "search reflexes." Could the mixture of logical categories go further?

Psychology must concern itself with the highest reactions of the organism as a whole, and must in consequence take account not merely of the stimulus and the final response, but the whole of an organism historically determined, and at all times and at all points saturated with affect and governed by those complex methods of adjustment and growth which we term the instincts. In short, if psychology is to retain the respect of the humanist, it must pursue to some extent the clinical method. Much therefore can be added to academic psychology if it allies itself to psychopathology. It is in this field that the processes of fragmentation are best studied, since they come into being in response to some strange biological necessity. The molecular method can be pursued by those who prefer the artificial atmosphere of the laboratory, but for psychological workers. Nature provides suitable material nearer at hand.

THE PATHOLOGY OF GASTRITIS.

CONCEPTIONS of gastritis have altered a great deal in the last few years. The older pathologists recognised the gross lesions caused by corrosives like carbolic acid and irritant poisons like alcohol, but the finer forms were lost in the changes produced by post-mortem degeneration and self-digestion of the stomach. In their study of pathology in the living, surgeons found ulcers and growths affecting the stomach, but gastritis as such was unsought for, and thus passed out of practical consideration. Further examination of the material obtained by resection of the stomach has, however, revealed changes in areas other than those invaded by growth or eroded by ulcer. The newer methods of investigation, especially histological observations on portions of the stomach fixed at body temperature, immediately after removal at operation, have thrown a new light on conditions of chronic gastritis. Konjetzny[1] found in such material that gastritis was present in every case of gastric ulcer examined, whilst in every case of duodenal ulcer there was gastritis as well as duodenitis. In 90 per cent. of stomachs resected for gross carcinoma he found evidences of gastritis in other parts of the stomach. Although Konjetzny believes that the gastritis is the cause of ulcer and of carcinoma, most workers see in these results at most the frequent association of gastritis with ulcer and cancer, and leave open the question whether the gastritis is primary or secondary. The great difficulty is that both gastritis and early carcinoma may be latent, and give no clinical evidence of their presence, so that microscopy is required to settle the question definitely. X rays may sometimes indicate gastritis by showing alterations in the contour of the mucous folds outlined by barium, but a negative result does not disprove its presence. It has long been recognised that inflammation of the lining of the stomach and duodenum may occur after severe burns on the skin, and lately F. Kauffmann[2] has investigated more exactly the importance of products of degenerated tissues in causing endogenous gastritis. In experiments on dogs he produced a dermatitis by sunlight treatment, and in other instances a sterile abscess by subcutaneous injection of turpentine. The sterile abscess or inflammation of the skin served as a source of the toxins derived from breaking down of proteins. The results observed were, besides degeneration in other organs (liver, kidney, and heart muscle), fatty degeneration of the gastric mucous membrane, especially in the pyloric region. A secondary inflammation in the submucosa was often found as well. All forms of degeneration were observed, from a simple fatty change or mucous catarrh to a severe erosive gastritis, implicating also the muscularis mucosæ and connective tissues of the submucosa. These inflammatory changes are brought about by the toxic products derived from protein degeneration in other parts of the body. Toxic or endogenous gastritis, he holds, may thus arise during infectious disease, or from the presence of inflammation in organs far removed from the stomach. A degenerating carcinoma in one part of the stomach may give rise to gastritis elsewhere in the organ. Bacterial toxins, which have hitherto been regarded as the essential causes of these lesions, may be found to play a less, though by no means negligible, part.

THE AFTER-HISTORY OF ATHLETES

"It is not perhaps too confident a statement that a properly trained person, man or boy, need never fear cardiac strain." (Allbutt.)

THIS sentence expressed concisely the attitude of a large section of the medical profession in 1909 to the question of possible injury to health resulting from severe physical exercise. Since that time no facts have come to light which would render the statement invalid; on the contrary, such evidence as there is—part of it was discussed in our columns last month—all tends to confirm the belief expressed twenty years ago by Sir Clifford Allbutt. In view of the increasing number of persons of all ages who regularly take part in athletics, the subject will continue to arouse interest. Investigations are still being put in hand all over the world, and carried out mostly upon groups of men who have specially prepared themselves for some special (and short) period of exertion—for example, a University Boat Race or Olympic Games—and have been limited to an examination of the subjects shortly after the end of the contest. In the *American Journal of Medical Sciences* (July, 1929) an account is given by Dr. Burgess Gordon and the late Dr. J. C. Baker of some observations on a trans-continental foot-race. Such a race provides unusual opportunities for studying the reactions of the body to severe effort continued for a long time. It also provided in this case an opportunity for the study of the effects of daily severe effort upon the comparatively untrained as well as upon the trained subject. The entries numbered 199, the eldest being 64, the youngest 17. Examination before the race showed that about 50 per cent. were physically under-developed, 3 per cent. suffered from respiratory infections, 4½ per cent. showed gastro-intestinal symptoms, 8 per cent. showed albuminuria. During the race only 7 competitors dropped out on account of exhaustion; these were unfit at the start and were untrained. Only 57 finished the full distance. Those who retired did so for a variety of reasons. "Shin splints"—a form of myositis with periostitis in the anterior tibial region—together with financial difficulties accounted for most of the withdrawals. The total mileage was 3484, and the daily average 44·2 miles. At the finish only 14 showed signs of fatigue; all the others were in excellent health. A careful physical examination carried out three days after the race showed no cardiovascular abnormalities. A striking fact is that 65 per cent. of those examined suffered from tonsillitis. Twelve months after the finish of the race inquiries were made as to the condition of the competitors; all the replies indicated that so far from being injured, they felt themselves to have benefited from the race. It is, of course, too early to judge of the effects of such a sustained severe effort on the health of the competitors, and it is to be hoped that careful records will be kept of the later history of those who took part in the race to add to those now available. We have already referred to the study by Morgan of the lives of University oarsmen (1829–69), and to his conclusion that the deaths definitely due to cardiovascular causes were in exactly the same proportion as in the general population. Meylan, who investigated the history of Harvard oarsmen, came to similar conclusions. R. W. Michell, of Cambridge, who examined 1200 rowing men and 410 players of Rugby football, found cardiac dilatation which persisted after exercise only in men with a history of either diphtheria or rheumatic fever, who had taken strenuous exercise while untrained. It is clear that on physical grounds no objection can be made to a habit of life which involves strenuous exercise, provided the individual is physically sound and properly trained. The available evidence is almost entirely confined to men, but there is no reason to doubt that it would be confirmed by investigations of the after life of women athletes. The various federated associations concerned with promoting sporting events for women in France have instituted a medical service and propose to insist on a certificate of fitness before candidates are allowed to enter for any event; this precaution, if followed up, might well form the basis of valuable statistical information. The efforts made to collect evidence to prove that exercise does no physically observable harm is a sign of the conviction, difficult to prove, but widely held, that a condition of trained physical efficiency not only leads to happiness and well-being, but goes hand in hand with general and especially mental efficiency.

OPTOCHIN IN OPHTHALMOLOGY.

CUPREINE is an alkaloid which occurs with quinine in cuprea bark, and the important property of ethylhydrocupreine is that it destroys pneumococci. It has been used medicinally in pneumonia, but it is mainly employed as the hydrochloride salt (optochin) in a one or two per cent. solution in eye affections, especially in pneumococcal ulcer of the cornea. Unfortunately its employment in this disease is attended by much pain. Dr. S. H. Browning, at the recent Oxford Ophthalmological Congress, suggested that it should not be applied direct to the cornea after it has become infected with the pneumococcus, but that the parasite should be attacked while it is still in the lacrymal sac, before the cornea has become infected. The popularity of optochin among ophthalmologists has suffered from its chemical name, for it is generally supposed that it is a derivative of copper and is therefore a dangerous substance to use on the eye. In fact copper does not enter into its composition at all, and the patient may be assured that the pain caused by its application does not indicate damage to delicate tissues.

RENAL EXTRACTS IN THE TREATMENT OF NEPHRITIS.

THE outlook in chronic nephritis is, as a rule, so bad that anything which offers hope demands every consideration. The possibility of a new therapeutic approach was mentioned in an annotation in our columns not long ago,[1] when it was suggested that injections of phosphate may perhaps be found useful. We observe that another line of possible treatment is being explored by Prof. Stejskal of Vienna, who has published[2] a small series of cases of advanced renal disease in which injections of fresh extract of kidney were given. Organotherapy has been abused so often that attempts of this kind are naturally received with reserve; but Stejskal's idea is neither altogether new nor devoid of foundation. A similar experiment was made as long ago as 1892, by Dieulafoy, and the theory of an internal secretion of the kidneys dates back to Brown-Séquard. It has often been suggested that in contracted kidney broken-down renal parenchyma is absorbed into the blood, and that such products are responsible for the high blood pressure and other changes found in this condition; and investigation has in some respects confirmed this hypothesis. Goldzieher[3] and others, injecting emulsions of kidney substance subcutaneously into rabbits, produced albuminuria and casts in the urine, and sometimes death. At the same time the adrenal bodies were found to be markedly enlarged with an excessive hyperplasia of the medulla. These and other experiments led him to the view that resorption of diseased kidney tissue caused an over activity of the adrenal medulla which was an important factor in the rise of blood pressure in cases of contracted kidney. Much may be said for this opinion; thus we know that if serum from a nephritic patient is added to a solution of adrenalin the pressor effect of the latter is considerably increased. Again, it is possible to have a very high blood pressure without obvious nitrogen-retention, which is evidence against the alternative hypothesis that such retention is alone responsible for the hypertension. Possibly both factors are concerned in producing so-called interstitial nephritis; thus primary impairment of the function of the kidney may lead to resorption of diseased renal tissue, which increases the liberation of adrenalin, whilst the subsequent accumulation of nitrogenous waste products in the blood may cause stimulation of the sympathetic, which acts again upon the adrenal medulla. At all events, whatever may be the connexion between renal damage and hyperplasia, Stejskal is able to record a remarkable reduction in blood pressure following injection of extracts of kidney. He used a sterile watery extract, containing as far as possible the unchanged renal lipoid bodies, but almost practically free from protein. This was injected in quantities of 2 to 5 c.cm. intradermally (so that absorption should be gradual) once or more into ten patients suffering from advanced contracted kidney, some in the late stages of uræmia itself. Injection was always followed by a fall in blood pressure, which was gradual and progressive, and in some cases this was persistent. This fall was not seen after injection of other tissue extracts and only occurred in cases of renal hypertension—that is to say, the renal extract appeared to be truly "organ-specific." The falls observed in the cases recorded were of 80, 40, 70, 120, 120, 90, 180, 90, 80, and 120 mm. of mercury—an average of approximately 100 mm. All were cases with very high values before the injection and obvious signs of terminal nephritis. Symptoms other than hypertension were not consistently affected, nor did the outcome of the disease seem to be much influenced, but the figures are certainly noteworthy. The theory is advanced that the fall may be due to some effect on the blood-vessels, perhaps of some hormone in the extract, which relaxes their powerful tonic contraction.

THE INDUSTRIAL HEALTH RESEARCH BOARD

THE change of title announced in its ninth annual report[4] by the Industrial Fatigue Research Board indicates that in future its object will be to study not merely the negative or pathological aspect of industrial activity, but also its positive side of promoting and maintaining good health. This step is in accord with the trend of modern medicine, for the doctor attempts to teach the patient how to be well and keep well, rather than to seek for cure of ills earned by wrong living. The body to be known as the Industrial Health Research Board came into existence to follow up war-time research into the evil effects of long hours and heavy work, but has now as its primary aim the acquisition of knowledge about conditions and methods of work most favourable to the workers. A glance at the variety of inquiries recently completed or in progress displays the wide scope of the Board's activities. Hours of work, the heating and ventilation of factories, vision and lighting in relation to output, the effects of noise and vibration, accident causation, labour turnover, repetitive work, vocational guidance and selection, sickness prevalence among printers, cardroom operatives and miners, humidity in mines, weight carrying, the physiology of exercise, the transfer of acquired skill, and the relation of age to the acquisition of dexterity, are all included among the subjects receiving consideration. Some activities concern problems of wide industrial importance; for others the material has been submitted by Government departments and industrial associations, while yet others are experimental researches carried out in laboratories. Knowledge is being gained; it remains to bring it to the attention of industry for practical application, for it should bring with it not only increase in health for the great working population, but increase in productive activity and wealth for the nation.

[4] Ninth Annual Report of the Industrial Health Research Board to Dec. 31st, 1928. H.M. Stationery Office. 1929.

A notable example of the type of information made available by the publications of the Board is the report just published, dealing with monotony in work.[5] The investigation was made on workers employed on such repetitive processes as filament winding, soap wrapping, chocolate packing, and tobacco weighing. Boredom was found to be a fairly general experience; only about one quarter of the workers escaping it. Boredom was held to be responsible for reducing the rate of work by from 5 to 10 per cent., and was more prevalent when operatives were paid on a time-basis than on piece-rates. It caused irregularity in rate of work, and affected particularly workers of superior intelligence whose productive efficiency was above the average. Workers doing entirely automatic work did not suffer much from boredom, for their thoughts could safely be detached from work and directed to more interesting subjects; it will be remembered that Auguste Comte claimed that chances for philosophic thought lay in such occupations, and looked to find pupils among such operatives. Boredom occurred most in semi-automatic processes which require enough attention to prevent mind-wandering, but not enough for the complete absorption of mental activity. Continued exposure to monotonous work causes adaptation, so that what is initially tedious and unpleasant may finally be tolerated or even mildly enjoyed. The suggestion made in this report that, by completing the mechanisation of the task, boredom is avoided and thought stimulated is decidedly unexpected. On this assumption mass production by repetitive work, when carried to a fine art, would cure the very trouble it has always been accused of causing. Here is a problem, elusive and difficult of approach, wherein progress must necessarily be slow; but the theories now put forward are ready for practical trial.

THE EVOLUTION AND PURPOSE OF THE LARYNX.

SOME years ago Mr. V. E. Negus set himself the task of tracing the reasons for the existence of the larynx and the steps of its evolution in response to the many demands made upon it. He started upon his researches without preconceived ideas, and allowed them to follow the directions which seemed to be indicated by his attempts to correlate structure and function of this organ throughout the range of animal life. He has examined the anatomy and physiology of the larynx, with its associated organs, from its earliest inception in the lung-fishes, and on this study has founded theories which he expounds with good argument in a recent publication.[6] The superficial idea that the larynx is "the organ of the voice" is obviously untenable from the evolutionary point of view. The primitive larynx is a valve placed on the floor of the pharynx at the top of the pulmonary outgrowth to prevent water and food from entering the lung sac; in the most primitive forms it is surrounded by a muscular sphincter only, but in some lung-fishes dilator fibres are also present, and in the axolotl lateral cartilages have appeared with the function of keeping the valve open when air is entering the sac. From this point Mr. Negus traces the evolution of the larynx with a wealth of detail which is of absorbing interest. The nose is primarily intended for olfaction; in fish, with few exceptions, it does not communicate with the mouth, but in air-breathing animals it is necessary for olfaction that air should pass through the nose. In order to retain this passage of air while the mouth is open during eating the epiglottis has been developed, and all keen-scented animals have a big epiglottis lying normally in contact with a long soft palate. As a secondary function in many rapidly running animals the long epiglottis reaching into the nasopharynx is valuable for maintaining a straight and open air-way to the lungs. In many lowly animals the larynx is of a domed shape, a configuration which prevents the entrance of air except when muscular action provides an opening. Some of the higher animals possess secondary valvular folds formed by specialisation of the thyro-arytenoid muscle; these prevent the entrance of air with the minimum expenditure of muscular energy, and the best instances are to be found in arboreal animals, particularly actively climbing monkeys, and in the higher apes and man. Mr. Negus believes that the primary function of these valves is to hold the thorax rigid, and so to give a fixed point of origin to the pectoral muscles. These valvular folds, which are the vocal cords of man, we owe to our arboreal ancestry; they have been further developed by the specialised use of our fore-limbs, and their employment for speech is a secondary function. These theories and other matters relating to the forms and functions of the larynx throughout the animal kingdom are supported by careful observations minutely recorded. The book gives evidence of much specialised knowledge as well as of original thought, and will be of interest to biologists as well as medical men.

RETINAL ADAPTATION AND FLICKER.

THE fact that the sensation produced by a visual stimulus persists after the stimulus itself has come to an end has long been recognised. In 1765 D'Arcy made the first recorded attempt to measure the persistence of an image by the rate at which a burning stick had to be whirled before it would give an impression of a continuous circle of light. The modern method is to fix a rotating disk, with one or more sectors cut out, in front of a source of light and increase the speed of its revolution until the flickering impression gives way to a sensation of continuous light. A recent report to the Medical Research Council shows that appreciation of rapid stimuli varies in different regions of the retina and is dependent on the condition of adaptation of the eye. To produce the sensation of flicker the subject being experimented on is seated in a cubical box with a minute window through which he can view a test patch, either directly (foveal vision) or at an angle (peripheral vision); the sectored disk is then made to rotate in front of a gas-filled lamp. The number of interruptions per second necessary to do away with flicker is known as its "critical frequency," and this varies according to the state of adaptation of the eye, according to the region of the retina on which the light falls, and according to the illumination of the test patch and its surroundings. During dark adaptation with high illumination of the test patch the critical frequency falls With low illumination of the test patch for the peripheral retina the critical frequency during dark adaptation rises. In the first case the cones are functioning, in the second case the rods. The brightness of the area surrounding the test patch is the most important factor in determining whether the critical frequency is of the rod or cone type. The outcome of investigations pursued by this method is to confirm what is already known in connexion with the phenomena of flicker. The "duplicity theory" of a double mechanism depending on the rods and cones respectively is assumed, and receives support from the results obtained. A novel suggestion based on the critical frequency of the retinal periphery in bright light is that the peripheral cones are functionally not identical with the foveal cones. If this is confirmed it will be in accordance with the known anatomical differences of the cones in the two regions.

AVERTIN FOR TETANUS.

The first instance, so far as we are aware, of the employment of avertin to control the spasms of tetanus, is related by Prof. Fritz Momburg and Dr. E. Rotthaus.[1] The drug appears to have been of the greatest possible service. The history of the case is briefly as follows: On July 21st, 1928, a girl of 7 fell down and got a small wound in the left patella. On July 28th, after an incubation period of only seven days, convulsions and stiffness of the limbs began. On the 29th severe trismus, opisthotonos, and rigidity of limbs supervened. Under avertin narcosis (0·17 g. per kilo) the wound was excised. Tetanus antitoxin was given intramuscularly, intravenously, and intrathecally to the extent of 20,000 units. During the next six days another 30,000 units were injected. During the 12 days following the operation the child was put under the influence of avertin 20 times. On two of the days she was made narcotic with avertin no less than three times. The dosage ranged between 0·1 g. and 0·18 g. per kilo of body-weight, and altogether she received 68·8 g. The worst days were the sixth to eighth, and the most distressing symptom was the terrible diaphragmatic cramp. For control of this, chloroform and oxygen were employed, and several times respiration ceased entirely. From the fourteenth day onward there were no convulsions, and the trismus diminished. On the forty-ninth day the child was discharged well. The authors are of opinion that the relief afforded by avertin during the acute stages of the illness was greater than any they had ever witnessed from other sedatives in similar conditions.

ANTENATAL CLINICS.

An official memorandum[2] outlining the organisation of a modern antenatal clinic, and the minimum scope of its activities, is likely to be scrutinised with jealous care, for this welfare scheme has not been accepted so cordially by doctors, midwives or, indeed, by patients, as have the infant clinics. In fact, the exhaustive scheme accepted by the Representative Meeting of the British Medical Association last month mentioned the existence of antenatal centres only to express firmly the opinion that the usual routine work done there could be done quite as well at the consulting room of the doctor or at the home of the patient. Since, however, a national scheme which might render antenatal centres superfluous is as yet only in the stage of a resolution of the Representative Body, the views of the Ministry of Health on the organisation and duties of these centres are welcome.

No encroachment on professional interests is threatened by the memorandum; on the contrary, emphasis is laid on the advisory nature of the clinics, and on the desirability of restricting their work rigidly to the supervision of normal pregnancies. It is reasonable to demand that supervision must be adequate, since a false sense of security may do even more harm than neglect. A distinction made by the Ministry of Health between consulting clinics, staffed by expert obstetricians, for which no rules are laid down, and examination clinics, such as those subsidised by voluntary organisations or municipalities. The medical officer of one of these examination clinics, whether giving whole or part time service, should be trained and experienced both in obstetrics and antenatal work, and should have held a resident appointment in a maternity hospital or at least three months' post-graduate instruction at a recognised school. His first duty is to advise patients coming independently or sent by health visitors to book their confinements with doctor or midwife forthwith. When midwives send cases they are to be encouraged themselves to attend, and to make the necessary examinations under supervision, so as to avoid duplication, but every patient should be examined by a doctor at least twice during pregnancy. The suggestion is made that on booking a case the midwife should ascertain the name of the doctor the patient would wish to employ in case of need during labour, and should inform him of this possibility, and of the antenatal condition. Doctors may not altogether welcome a form of contingent booking which morally binds them to be available if difficulties occur, but on the other hand an unexpected summons to an unknown case may be even more unsatisfactory. Whatever the outcome of the labour, the midwife is to be asked to report to the clinic on its course, the local authority being advised to offer a small fee for a courtesy which is indispensable to the collection of reliable statistics. When a doctor has been booked for the confinement, and his patient attends the clinic, no examination should be made without his consent; he also is to be asked to report to the medical officer on the labour, no fee being mentioned in this connexion. Since, however, it is laid down that a doctor wishing to transfer the whole or part of the antenatal care of a patient to a clinic should be able to do so, he stands to gain so much from the facilities to be offered, which include reports on abnormal cases, that he is not likely to grudge information in return.

The reservation of beds in hospitals for abnormal maternity cases referred by clinics as well as by doctors is recommended in the memorandum; reciprocal advantage is an arrangement for patients living far from the hospitals where they intend to be confined to attend the nearest clinic during the whole or part of their pregnancy. One brief sentence implies the desirability of the extension of the maternity service throughout the country on lines already followed by the Hampstead local authority—the provision of obstetric consultants. The minimum number of routine examinations, according to the schedule, works out to nine or ten in normal cases, between the first examination at the sixteenth week and the confinement. This number may seem excessive, but most of the examinations need involve no more than measurement of uterine height and girth, auscultation of fœtal heart, tests of urine, and inquiries as to general health, and can be conducted by the midwife. At the thirty-second and thirty-sixth week the medical officer should endeavour to ascertain the presentation of the fœtus and the relation of head to pelvis.

The disadvantages of any system under which the doctor who examines a woman during pregnancy does not conduct her labour are obvious. But antenatal centres staffed by medical officers, to which practising midwives are welcomed with their patients, are a compromise which succeeds in providing for medical supervision in cases deemed to be normal, and for the diagnosis of abnormal ones, who are referred to the doctor concerned. In the present transitional stage of our maternity services it is not easy to suggest a better antenatal scheme than the one which would be available if all the welfare centres were raised to the standard indicated in this memorandum.

ANIMAL EXPERIMENTS.

BY a coincidence, the annual return[1] from the Home Office relating to experiments on living animals is issued this week, when the general arguments justifying vivisection are set out so eloquently in our columns by Prof. A. V. Hill. We need do no more than summarise the details of the return.

The names of 1310 persons who held licences for experiments on living animals during any part of the year 1928, and of the 256 registered places where such experiments can legally be performed, are set out. The number of experiments performed was 315,891, and these are classified according to their nature. Some 15,000 were performed under anæsthesia; this group includes all operations more severe than subcutaneous venesection. The rest, amounting to over 300,000, were mainly inoculations, but feeding experiments, the administration of substances by the mouth, by inhalation, or by external application, and the abstraction of blood by puncture or simple venesection, also come into this category.

It is often wrongly assumed that most of the operations are done in the hope of directly acquiring new knowledge; the truth is that the large majority are not experiments in this sense, but are biological tests necessary for the production or standardisation of drugs, serums or vaccines, or inoculations to confirm diagnosis. One licensee did over 60,000 experiments jointly with others, for the purpose of standardising drugs, and nearly all those who record large numbers of experiments performed under certificate A alone (that is, without anæsthetics, on animals other than dogs or cats, horses, asses or mules) were working for public health authorities, or in connexion with standardisation. The only reason for emphasising this distinction in purpose is to show how rigid is the supervision over even the most trivial routine animal inoculations, and how strict are the rules governing the issue of licenses. Registered places are constantly being visited by inspectors, mostly without previous notice, and the animals have been found suitably lodged and well cared for. The three irregularities reported during the year were obviously inadvertent and unimportant.

THE National Radium Trust have appointed Mr. P. Barter, of the Ministry of Health, Whitehall, to be Secretary of the Trust, and Mr. Niven F. McNicoll, of the Department of Health for Scotland, to be Assistant Secretary.

PURE RIVERS SOCIETY.—At a recent meeting of this society, whose address is 1, Lincoln's Inn-fields, London, W.C.2, resolutions were forwarded to the heads of Government Departments concerned with rivers pollution. The Minister of Transport is urged to make it a condition of grants to local authorities for road-making that they shall not use on roads any poisonous substance which may affect rivers. The Minister of Agriculture and Fisheries is invited to arrange that subsidies to beet-sugar or other industries should only be granted on condition that adequate provision is made against pollution. The Minister of Health is asked to obtain power to set up River Boards on his own initiative without, as at present, having to wait for applications by the local authorities. It is also urged that a central authority on the lines of the Railway Commissioners should be set up to deal with river pollution, and a resolution asking for an amendment of the law relating to prosecutions for pollution has been sent to the Prime Minister.

The Clinical Interpretation of Aids to Diagnosis.

A Series of Special Articles contributed by Invitation.

XXXIX.

THE DICK AND SCHULTZ-CHARLTON TESTS.

THE Dick test closely resembles the Schick[1] test. People who are susceptible to scarlet fever and have no scarlet fever antitoxin in the blood, show a red flush on the forearm when 0·2 c.cm. of an appropriate dilution (about 1 in 1000 to 2000) of scarlet fever toxin is injected intracutaneously. This toxin is the filtrate of a broth culture of the streptococcus associated with scarlet fever. By the injection of about 5 c.cm. of a good concentrated scarlet fever serum, immediate protection, lasting from two to three weeks, can be conferred on such people or they may be given prolonged immunity by active immunisation with three or four graded doses of the toxin. The same general conclusions apply, *mutatis mutandis*, as in the Schick test, though the concordance between a negative reaction and degree of immunity is less close. Thus, whereas practically all patients suffering from diphtheria are Schick-positive, from 5 per cent. to 20 per cent. of those with scarlet fever when first seen may be negative to the Dick test. It is possible that the average Dick-negative patient does not possess quite as high an immunity to scarlet fever as the Schick-negative reactor does to diphtheria.

Reading of Results.

The reading is usually made overnight, though a positive reaction in some patients may be easily read as early as four to eight hours after the injection. The red flush usually fades 48 to 72 hours later. When the control toxin has been sufficiently heated, "pseudo" reactions are so rare that "control" injections, after a little experience of their use in a given group of people, may often be dispensed with.

Treatment and the Test.

The Dick test may help in deciding on the treatment and disposal of a patient with a rash possibly due to scarlet fever. A positive Dick reaction will be consistent with the diagnosis of scarlet fever; unfortunately, a negative response will not exclude scarlet fever, for in a given series of patients with scarlet fever perhaps 1 in 10 might be Dick-negative. It is curious that the swab and direct smear from patients with rash is not more widely employed in diagnosis. The smear from the typical scarlet fever patient shows numerous diplococci or short chains of cocci. Swabs in almost every instance yield large numbers of colonies of hæmolytic streptococci on a blood plate after overnight growth in the incubator; the zone of hæmolysis is easily seen with the naked eye. From patients with rashes due to measles, rubella, drugs, or enemata, this blood plate with almost pure culture of hæmolytic streptococci is rarely obtained, though a close examination may yield a few colonies in perhaps 5 to 20 per cent. of the patients tested, as in any sample of the general population. The examination of swabs from convalescent patients has already been discussed in this series by Dr. J. G. MacCartney (THE LANCET, 1928, ii., 565). Several writers have recently brought forward some evidence suggesting that the convalescent whose swab still yielded hæmolytic streptococci on discharge was more apt to cause "return cases" of scarlet fever than the convalescent with a negative swab, and in Germany the necessity of a negative swab before discharge has been officially discussed. Since at present probably from one-third to one-half of the convalescents discharged after scarlet fever still have hæmolytic streptococci in throat or nose, a new addition to the perplexities of the medical officer of health appears to be threatened.

---

[1] The Schick test was discussed in this series last week.

Contacts.

The tests aids us in dealing with those who have been or are exposed to the risk of infection. Though some authors have reported instances of scarlet fever in people who have given a negative Dick reaction, these are rare. Fifty patients under Dr. Sage Sutherland's care in Manchester became exposed to infection; of 37 negative reactors, none suffered from scarlet fever, while of 13 positive reactors, six became infected. Of 168 Dick-positive reactors under Dr. W. T. Benson's observation in Edinburgh, 36 contracted scarlet fever, while of 97 negative reactors none was atacked. Nursing staffs naturally Dick-negative, or made negative by immunisation, in Edinburgh, Birmingham, Aberdeen, Cardiff, and other large isolation hospitals, remain free from the disease. It is thus reasonable to act on the assumption that a contact who is negative to the test, either naturally, after active immunisation, or after receiving a prophylactic dose of antitoxin, will not develop the disease (though in the last instance the protection is but temporary). A dose of 5 c.cm. is successful when used as a routine in hospitals to control ward outbreaks; in this way the necessity for closure of wards is reduced or wholly avoided.

The Schultz-Charlton Test.

If the serum of a patient convalescent after scarlet fever (which contains the specific antitoxin), or the serum of an immunised horse, be injected intradermally into an area of skin showing an early scarlet fever rash, a blanching of the rash an inch or more wide will be found next day, perhaps persisting until the rash fades. This result is apparently completely specific; a rash which shows the blanching must be due to a scarlet fever streptococcus. Unfortunately, it is in testing characteristic vivid rashes (where no confirmatory test is called for) that the blanching is most definite, while in some atypical rashes in scarlet fever the blanching may not occur, nor does it appear if the scarlet fever rash be more than three days old.

Active Immunisation.

When active immunisation is contemplated the Dick test may be used to find those susceptible to scarlet fever, though children are to-day injected by some authorities without preliminary testing. There is no reason why the Schick and Dick test—and the later immunisation where needed—should not be done simultaneously; the Dick control injection may be omitted without much risk of error.

Reservations.

The test has been used on a large scale in clinical work and its utility clearly demonstrated, but there are a number of points and exceptions to the usual rules not at present understood. Thus, a few patients on admission with undoubted scarlet fever are negative to the ordinary Dick test; a number of patients on recovery, even though untreated with serum, remain positive to the test; the young baby, even though born of a Dick-positive mother, is often negative to the test and may be left to suckle from a mother suffering from scarlet fever without risk that it will develop the disease; adult rabbits will die from intravenous injection of scarlet fever culture or toxin while young rabbits may escape. These discrepancies are not met with in connexion with the Schick test. One suggested explanation, put forward mostly by American and German workers, is that the Dick-positive response represents an "allergy," a sensitiveness to the protein or other constituent of the scarlet fever streptococcus. For a full discussion of these conceptions (which at present concern the research worker more than the practising physician) the original papers must be consulted. It is possible that the truth lies halfway and that as in the tuberculin reaction, both a specific toxin and a specific sensitising body, protein or carbohydrate, play a part.

Summary.

The typical patient suffering from scarlet fever is positive to the Dick and Schultz-Charlton tests, and a blood-agar plate shows almost pure culture of hæmolytic streptococci. These three tests, used with a recognition of their limitations, are of aid in the diagnosis and prevention of scarlet fever.

THE CHROMOSOME IMBALANCE THEORY OF CARCINOGENESIS.

BY J. A. MURRAY, M.D., B.Sc. EDIN., F.R.S.,
DIRECTOR OF THE IMPERIAL CANCER RESEARCH FUND.

Boveri's essay, "Zur Frage der Entstehung maligner Tumoren," was published in 1914. The stern preoccupation of the war and Boveri's death prevented any widespread discussion of his views. Recently both in Germany and in America renewed interest has been evinced in the theory he propounded and an admirable and faithful translation into English has been made by Mrs. Boveri.[1] Prof. M. N. Metcalf, who provides a sympathetic introduction to the translation, has, in another place, deplored that as the only pupil of Boveri engaged in cancer research, I have not explored the possibilities opened up by Boveri's theory. This fact, and the intrinsic interest of the theory, lead me to take this opportunity to give a summary of it and the reasons for my own attitude.

The Theory Summarised.

The theory may be summarised as follows. The cancer problem is a cell problem. The cancer cell is essentially a defective cell, and the defect is in the nature of an inherent permanent change imposed on it and all its progeny, at the time it arises from a previously non-cancerous ordinary cell of the body. One of the most clearly demonstrated ways in which a permanent transmissible defect can be produced in a cell is by the elimination of a chromosome or chromosomes from the nucleus, as occurs in multipolar mitotic division. As chromosomes each divide into two in mitosis, it is clear that the presence of more than two centrosomes in the mitotic figure must lead to an unequal distribution of the daughter chromosomes to the resulting daughter cells. Boveri's analysis of the consequences of a primary multipolar division of the disperm fertilised sea-urchin egg showed that the larvæ which develop are pathological when all the chromosomes take part in a single distorted equatorial plate surrounded by four attraction systems (tetraster). The four quadrants of the resulting blastula are pathological to different degrees and in different ways. Two of these pathological pictures are extraordinarily suggestive and impressive. In one, the cells leave the blastula wall and migrate into the blastula cavity, forming an irregular heap of rounded or polygonal cells. In the other the cells separate from each other and from the remainder of the blastula, and float away as free elements in the surrounding sea water. One seems to have in diagrammatic simplified form loss of differentiation, the breaking up of physiological union, and metastasis formation. This observation undoubtedly was the germ of the theory in Boveri's mind. In the first instance, and in its simplest form, the cancer cell arises singly as one of the products of multipolar mitosis, in which the fortuitous distribution of the half-chromosomes has resulted in a nucleus, capable of continued existence, but defective in chromosome-individuals necessary for the ordered growth and metabolism of the normal cells.

---

[1] The Origin of Malignant Tumours. By Theodor Boveri. Translated by Marcella Boveri. London: Baillière, Tindall and Cox. 1929. Pp. 119. 11s. 6d.

Certain Objections.

When Boveri came to write up this idea in the form of a connected theory many further observations and analogies were drawn upon, and the discussion of objections, to which a separate chapter is devoted, is a fascinating example of subtlety, erudition, and scientific humility. He at once realised that the uniformity of the tumours which arise when the stroma of a transplantable mouse carcinoma undergoes sarcomatous transformation and, still more, the uniformity of the filterable tumours of the fowl, were fatal to the hypothesis which, in its original simple form, depended on the fortuitous result of multipolar mitosis. To meet this difficulty it was assumed that cell-poisons acting specifically on single chromosomes, inhibiting or enhancing their action, might intervene in the process. The analogy of certain hybridisation experiments with sea-urchin eggs was cited in support of this assumption. Baltzer, in fact, had shown that in some crosses only a few of the male chromosomes entered the fertilisation spindle and took part in the formation of the embryonic nuclei. The others remained inert and were handed on passively to one or other daughter cell till they degenerated. The theory of chromosome imbalance thus acquired a considerable increase of strength having, like the incalculable Kai Lung, a tale to fit any possible concatenation of circumstances.

Conclusion.

It is idle to speculate how the intensely practical experimental mind of Boveri would have reacted to the great acquisition of knowledge of carcinogenesis in the last ten or twelve years. A theory or hypothesis which could not lead to the planning of decisive experiments had little permanent appeal for him, and he candidly reports the complete unsuccess of the large number of experiments he himself carried out to test his views. On sending me a copy of the original paper in 1914 he wrote: "I expect you will smile at it, but one must do what one can." In spite of the most serious consideration of the theory, and an affectionate admiration for the author, I have never been able to acquiesce in the fundamental conceptions of cancer which underlie it. Loss of differentiation, loss of physiological control, are the negative side of the cancer cell. Its independence and greater adaptability to external conditions seem to me rather to indicate an acquisition of new properties, not defects. The recent attempt of Bauer still further to fortify the hypothesis by substituting destruction or inhibition (or conversely over-activation) of single genes only has the effect of withdrawing still further the theory from experimental proof or disproof and thereby lessening its utility. It is now many years since I relinquished the attempt, after laborious trials, to find constant significant alterations in chromosome numbers, nuclear size, or nucleus-protoplasm ratio in cancer cells. The facts, so far as they went, did not harmonise with Boveri's theory. The subsequent modifications, while they may diminish the weight of this negative evidence, do not furnish compensating advantages in devising more conclusive tests of it's validity.

A REDCAR HOSPITAL.—The Yorkshire borough of Redcar, which has a population estimated at 22,000, and receives many thousands of visitors every year, has hitherto been without a hospital. The need has now been supplied by the presentation to the town by Mr. Arnold Stead of his residence, Everdon, as a memorial to his father. The building, which has been adapted to hospital purposes, contains seven beds, and has been fitted with apparatus for sunlight treatment, was last week opened by the Dowager Marchioness of Zetland.

Edinburgh University: Address to Graduates in Medicine.

THE Professor of Bacteriology, Dr. T. J. Mackie, was charged with the duty of addressing new graduates in medicine of Edinburgh University last month. He reviewed the present system of medical education, which needed drastic revision. The outstanding faults of the educational system now in force were the products of its growth and evolution. Medicine was once entirely art; it was now mainly science, and was one of the great divisions of biology. The medical worker might well be the supreme biologist, and it was all-important that at the very threshold of university study there should be a rational introduction to general biology—not botany, zoology, or anatomy as such, but the science of life in its broadest aspects—leading up to the more specialised study of the biology of the human species, with whose vital problems the doctor had to grapple throughout his career. The physical sciences lay at the very foundation of biology and medicine. Some medical schools had attempted to relieve the pressure of their curricula by separating off such basic studies in the first of a six years' course, leaving five years for purely medical subjects. The addition of a year to the curriculum seemed at first sight the obvious solution of a difficult educational problem, but it might still be possible to maintain the original quinquennium by a closer coördination of these preliminary studies, one with another, and with that of anatomy and physiology during the first and second years. The latter subjects constituted an integral part of the fundamental biological training and with biology, physics, and chemistry, made up the complete basic structure of their educational edifice. From the study of normal biological phenomena, the student turned to the abnormalities, accidents, and infirmities from which humanity sought protection and relief. From biology as a pure science he passed to the applied biology of practical medicine. The question arose whether the existing system of examinations in subjects might be replaced by yearly examinations, corresponding to annual units of instruction. As to the clinical part of the curriculum, it was sometimes claimed that the scientific attitude was incompatible with practical work as a doctor, and that the so-called medical art should be inculcated by bedside training according to thoroughly practical tenets, leaving scientific medicine as a thing apart in the research laboratories. If medical training were stripped of its scientific instruction, however, it would hardly justify a University degree, and would be degraded back to a mere apprenticeship. The practice of medicine was becoming more and more of an applied science, and necessitated a training in fundamental principles. The practitioner was constantly confronted with problems that were only to be elucidated by scientific method. It must also be remembered that scientific applications and laboratory methods had in modern times proved their value in medicine to such an extent that the hospital ward was no longer the centre of gravity of medical enterprise. The laboratories were serving humanity in the cure and especially in the prevention of physical suffering, as much as were the clinics. Lastly, a medical education would serve our civilisation poorly if it did not kindle fires of research among those pupils of originality and initiative who were responsive to the inspiration of scientific teaching. Our present system of training did not provide sufficient opportunities for those who might wish a more complete science training. On the analogy of the honours degrees in other faculties there might be instituted an Honours Degree in Medicine, connoting special and advanced study of one or more branches of medical science in addition to the general curriculum.

Bi-Centenary of the Edinburgh Royal Infirmary.

Arrangements for the celebration of the bi-centenary of Edinburgh Royal Infirmary have now provisionally taken shape. The anniversary of the opening of the institution fell on August 6th, and as that is the time of the year when holidays take a great many away from the city, it has been decided to defer the public part of the celebration till early in October. August 6th, however, did not go unmarked; on that day, an illustrated commemorative card was distributed to every patient and every member of the staff in the infirmary. The proposal for October is that the bi-centenary should be the subject of a thanksgiving service in St. Giles Cathedral, and, later in the same day, of a public meeting, when an appeal will be launched for the extension scheme on the site of George Watson's College. The intention is to provide a maternity and gynæcological hospital for the accommodation of 240 patients at a cost of £300,000; certain notable donations have been already made to this end.

The late Mr. A. G. Miller.

The death occurred in Edinburgh on Monday, July 29th, of Mr. Alexander Gordon Miller, consulting surgeon to the Royal Infirmary, Edinburgh, in the eighty-seventh year of his age.

Mr. A. G. Miller was the son of Prof. James Miller, formerly professor of surgery in the University of Edinburgh, and was educated at Edinburgh Academy and the University, graduating in medicine in 1864. He held house appointments in the Infirmary, took the Fellowship of the Edinburgh College of Surgeons, and in 1877 became assistant surgeon to the institution. Five years later he was appointed full surgeon in the new Royal Infirmary which had just been built. It will be seen by the dates that when he received his staff appointment the question of antiseptic surgery and the value of the Listerian system was still acute, when he, with most of his younger contemporaries, recognised the value of the new work, while the seniors on the staff were unable to reconcile themselves to the revolutionary theories. But it must be remembered that many of those seniors were not, strictly speaking, consulting surgeons, but rather could be described as successful general practitioners, who carried on surgical work if and when required. Miller displayed in his surgical work considerable originality, being the deviser of a method for excising the knee, a method for reducing dislocation of the shoulder, and a new technique for disarticulation at the knee-joint. The general level of his teaching in the wards secured his appointment as lecturer on surgery and as an examiner in that subject at the University, and also at the Scottish Royal Colleges. Although he had outlived most of his colleagues, there are still students who remember the interest which he took in their careers, his enthusiasm as a volunteer, and his strong advocacy of the temperance cause. He was, and for good cause, very highly respected.

Dr. Thomas W. M. Cameron, M.R.C.V.S., of the London School of Hygiene and Tropical Medicine, has been appointed lecturer in Helminthology in the Department of Zoology of the University of Edinburgh, and the Royal (Dick) Veterinary College.

UNITED STATES OF AMERICA.

(FROM AN OCCASIONAL CORRESPONDENT.)

Rural Medical Service.

THE results of a study of 800 replies to a questionnaire on the availability, quality, and cost of medical service in rural districts throughout the United States is published in a recent issue of *The Farmer's Wife.* It is found that the average distance of the farmer from the nearest doctor is just over seven miles; the average time required for the doctor to reach the patient is, in summer, half an hour, and in winter, 50 minutes. Nearly one half of the farmers, however, are not satisfied to patronise the nearest doctor for all troubles, though nearly 90 per cent. will do so for minor ills. Where the choice of medical attendant is exercised, the average distance travelled by the doctor leaps from 7 miles to 19. Specialists are even more remote; 15 per cent. of the farms, for example, have no nose and throat specialist within a radius of 50 miles. The average distance to hospital is 18 miles, and the time needed to reach it 40 minutes in summer and 67 minutes in winter. There is some evidence that the modern public health campaign has penetrated even to remote districts. Two-thirds of the school-children have health inspection at least once a year, though only in about half of these inspections does a physician take any part. A nurse is usually present and active. In the event of sickness in the home, according to over 80 per cent. of the replies, a nurse is available within 12 hours. During the year the "average" farmer spends 105 dollars (about £21) on expense due to sickness. Of this, rather less than half goes in doctor's bills. The average fee charged for a home call was $7.63, for an "office" visit $1.50. It is interesting to learn that 95 per cent. of the homes had summoned a doctor for the birth of the last baby. The average fee for a confinement case is $28.33.

The Prevalence of Undulant Fever.

At a recent meeting of the Georgia State Medical Association Dr. E. A. Banker, jun., drew attention to the increasing importance of undulant fever in this country, and recommended that it should be made a reportable disease in all States. From the State of New York is reported the ironic fate of a health officer who declined to use pasteurised milk, favouring instead a small and well-supervised dairy, which gave milk unusually rich in cream. He fell victim to a continuous fever, and the State department, aiding in the diagnosis, was able to isolate *B. abortus* both from the patient's blood and from the blood and milk of one of the cows. At the same meeting Dr. T. E. Oertel, of Augusta, pointed out that serpents are still plentiful in the South-Eastern States, but that very few of them are poisonous. The great majority are not only highly ornamental but are useful to the farmer by feeding on vermin, and should be protected. The water snakes, however, should be destroyed for the protection of fish. By far the most important of the venomous snakes is the rattle-snake, which is easily recognised. There are also two species of coral snakes in the United States, only one of which is found in the East. During the year 1928 31 cases of snake-bites from poisonous serpents were reported in Georgia.

Possible Danger of Artificial Refrigerators.

The rapidly increasing use, partly no doubt the result of concentrated advertising, of artificial refrigerators in place of the once universal ice-box, lends a special interest to a coroner's inquest held at the beginning of this month in Chicago. The coroner's jury was composed of a group of distinguished scientists, including Prof. Hayhurst, of Ohio State University, and three professors from the University of Chicago. The coroner's chemist gave evidence that death was due to methyl chloride poisoning, and that guinea-pigs placed in the deceased's flat had also died from the same cause. A definite leak had been found in the refrigerator, and the air of the flat was found to be heavily contaminated with methyl chloride gas. The jury found that the cause of death was inhalation of this gas, and recommended that steps be taken to prevent further sickness and death from such causes. The city health officer and other physicians believe that there have been other cases of sickness and death from this cause in recent months.

Public Health Services.

PORT OF LIVERPOOL.

IN his report for 1928 to the Liverpool Port Sanitary Authority Dr. A. A. Mussen mentions 5110 visits of inspection paid to ships, of which 933 (948 last year) had nuisances on board; there were 3131 (3297) dirty forecastles, and 363 (409) foul w.c.'s. He explains that it is when men are leaving ships they permit their forecastles to become nuisances. Complaints are rare when crews are still attached to the ships, and this may be why dirty forecastles are less often noted on foreign ships, for only British ships discharge their crews at Liverpool.

Of 39 cases of enteric fever mentioned as occurring during voyages that brought ships to Liverpool, 23 were among the crews; the same was true of 28 of the 52 varicella cases. Sixty cases of tubercle were landed, their origin being unstated. No cases of cholera, plague, or yellow fever were brought ashore, but 12 rats were found to be infected with plague, none of which, however, was caught ashore. In 1928 plague was prevalent in Aden, Lagos, Rangoon, and Bombay: cholera in Calcutta and Shanghai; and yellow fever in South America and West Africa. Of anthrax, 8 cases appeared in or near Liverpool and one died.

On ships 29,189 (31,357) rats were found, and in the port 2250 (2382)—a decrease in spite of increased activity in the search. The city yielded 16,664 (17,671). This is the third year in which the total found in Liverpool has decreased, the figures being 55,012 in 1926, 51,410 in 1927, and 48,103 in 1928. Rats are decreasing on Liverpool ships, probably because the ships are being better rat-proofed. On 45 "rat-proofed" ships fumigation killed 3·1 rats per ship; on 68 ships, not rat-proofed, fumigation killed 25·5 per ship. On 16 ships of two unnamed companies which rat-proof their ships and keenly trap rats, no rats were found at all; 31 ships of other companies averaged 14 rats per ship. Rats are to be reduced, Dr. Mussen thinks, by careful supervision when loading abroad, by rat-proofing to prevent them from straying round the ship in search of water or nesting places, by trapping, and by periodic fumigation. Cats on board ship are too well fed to be any safeguard. Since October all foreign-going ships of the world have been examined for rats; if found free they get a deratisation exemption certificate, valid for six months; if rats are found fumigation is done and a deratisation certificate, also valid for six months, is issued under the sanction of the International Sanitary Convention. This Convention, signed at Paris in 1926, is set out at length in the valuable Appendix to the report.

The Seamen's Dispensary dealt with 2043 (1843) cases of venereal disease. In every 100 cases there were 33·5 of syphilis (a quarter of them not yet Wassermann-positive), 4·5 of soft chancre, and 62 of gonorrhœa. These are cases, not first infections. Of 101,725 male attendances in all the Liverpool treatment centres, 1579 were for soft chancre; but of 15,265 female attendances, only 4. Of 20,088 aliens who arrived at the port 9 were certified—5 for mental deficiency, 2 for venereal disease, 1 for hyperthyroidism, and 1 for epilepsy. Of 116,083 emigrants, 16 were rejected for infectious diseases. The arrangements for food inspection are given in detail; the amount condemned and supervised was 1967 (2621) tons; in this section of the report is an interesting discussion of the methods of preparation of currants in Greece. The Port Sanitary Authority gives certificates of disinfection before the export of rags, &c., and of the wholesomeness and cleanliness of preparation of exported foods.

This year's report contains much useful information, and the general provisions of the International Convention set out in the Appendix make it clear how greatly the confidence of the world in the work of the Port Sanitary Authorities of the other nations—formerly discussed with so much suspicion—has increased in the last 30 years.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE following are some 1928 statistics of two large east coast seaport cities:—

Name of city and estimated (R.-G.) population.	Birth-rate.	Death-rates per 1000 of the population.					Death-rates per 1000 births.		
		All causes.	Tuberculosis.	Cancer.	Respiratory diseases with influenza.	Heart disease.	Infant and neonatal mortality.	Young child (1–5 yr.) mortality.	Maternal mortality from childbirth.
Edinburgh .. (428,454)	17·3	13·7	1·05	1·60	2·2	2·1	75/30	39	7·8*
Hull .. .. (297,600)	20·5	12·8	1·21	1·44	2·2	2·3	79/30	30	4·1*

* These figures are not strictly comparable owing to the different methods of classification adopted by the English and Scottish Registrars-General. The figures for puerperal sepsis alone are Edinburgh 2·7, Hull 2·1; and the Hull figure for childbirth becomes 4·6 if three deaths associated with pregnancy and child-bearing be included.

Edinburgh.

Dr. W. Robertson describes a death-rate of 13·7 as a satisfactory figure, but points out that the congested areas sully the vital statistics. Thus the death-rates for St. Giles, St. Leonards, St. Andrews and North Leith wards were 18·5, 16·2, 15·7 and 17·2 respectively. The infant mortality-rate is the lowest ever recorded for the city. The scheme for providing cookery lessons for the mothers, with elementary appliances, such as are available in the poorest homes, has proved a great success. Illustrations are given of the lessons in progress, and of safe playgrounds for the children while the mothers are so engaged. A great point is made of using simple and often neglected valuable foods. One aim of the cookery lessons is to stimulate the housewives to desire a house in which the meals can be prepared with far greater ease. The various housing schemes have already demonstrated their value in the improved health of the children, and it is further hoped that the almost magical effect of a sojourn in a convalescent or holiday home on slum children should result in much more accommodation of this kind being provided. Recently four improvement schemes have been initiated involving nearly 2000 houses. Further progress depends upon the rate of building. Reconditioning is not likely to be of much service in the congested areas of large Scottish towns, in which the old-type of tenement with its long dark passages, gloomy ill-ventilated lobbies and centrally placed stairways prevails. The architect finds that it is cheaper to build new houses than to gut and recondition such old properties. Reconditioning, if it can be done cheaply, may occasionally be of some service for old couples, single persons and childless folk. For growing children the out-lying areas are the places for housing schemes. The worst statistics are recorded in those wards where one and two-roomed houses are most numerous. Thus St. Giles has 1142 single-roomed dwellings and 694 of two rooms, whilst St. Leonards ward has 1206 single-roomed and 2484 two-roomed houses. Many citizens have gladly seized the chance to change over into well-equipped municipal houses. The slum-dweller must now have his turn, says Dr. Robertson, and those who can afford to pay economic rents should not look to corporations to provide houses for them, but get into touch with building societies, &c. Schemes for providing well-conducted hostels for men and women are taking definite shape.

Turning to infectious diseases, Dr. Robertson points out that economies have been effected by treating more of the scarlet fever cases in their homes. Immunisation against diphtheria among school children can only proceed slowly with the present staff. The hospital experience during the year showed that immunisation by toxoid-antitoxin injections did not ensure absolute protection among the nurses. There were two cases of diphtheria in nurses, who had apparently been successfully immunised, but in each case the attack was mild and recovery rapid. On the other hand, there were no cases of scarlet fever among the immunised nursing staff. Dr. David Lees, the V.D. medical officer, brings out several interesting points. A much larger number of patients now come to the clinics to have their condition investigated, who, after searching tests, show no evidence of venereal infection. Thus the non-venereal cases attending the clinic have increased year by year from 727 in 1924 to 2362 in 1928. Repeated examinations are necessary to discover evidence of the gonococcal infection in ophthalmia cases, if a silver preparation has been used before attendance at the clinic. Vulvo-vaginitis in children, usually the result of sleeping with infected parents, requires long periods of hospitalisation for its cure. In-patient treatment is much more valuable in female infections and increased bed accommodation, especially for married women, is an urgent necessity. Intensive in-patient treatment for a few weeks often saves much time and suffering. The number of defaulters, who discontinued treatment before being cured was 863 and the report of the nurses, who follow up these defaulters and endeavour to get them to resume attendance, shows how hopeless this work frequently is, and justifies the proposals for some form of compulsion.

The death-rate from pulmonary tuberculosis was the lowest ever recorded and there is a satisfactory decline in non-pulmonary tuberculosis. During the year 16 patients were admitted to the Polton Farm Colony and 11 discharged. The expenses for the upkeep of the colony amounted to £3097, and the receipts from the sale of pigs, poultry, eggs and other produce were £1557—a net expenditure of £1540.

The testing of the Victoria Hospital tubercle-free herd revealed only one reactor, which had a small lesion in the mediastinal glands. The municipal farm has been reconditioned and during the spring and summer a herd of about 80 tubercle-free cattle was purchased, amongst which at the November retesting these was one doubtful reactor. All the municipal hospitals are now supplied with milk from this farm. The city cow population is 3421, and amongst these 48 tuberculous cows were found during the year and eliminated from the herds. The incidence of tuberculosis in the city and district as revealed by post-mortem statistics at the abattoirs, says Mr. A. Gofton, the chief veterinary inspector, shows no material change as compared with former years. Of 110 bulk samples of country milk 6 or 5 per cent. were found to be tuberculous—a smaller percentage than the average of recent years. Of the 187 samples of milk taken under the Sale and Food and Drugs Acts the city analyst reported 42 as adulterated. The average milk fat of all these statutory samples was only 3·48 per cent., which may be compared with the average composition of similar statutory samples, also including the adulterated samples, in the report of the Lancashire public analyst for 1927. It is there shown (p. 7) that the aggregate samples, numbering 87,981, taken in eight districts in the North of England over a period of years the average fat was 3·64 per cent., whilst the lowest average among the eight districts (Liverpool) gave an average of 3·60 per cent. One dealer in Edinburgh with two previous convictions against him was fined £35 for selling milk 30 per cent. deficient in fat and containing 38 per cent. of added water. There is said to be room for more antenatal work in Edinburgh, especially in the outlying parts of the city. Dr. T. Y. Finlay (M. & C.W.M.O.) points out that this work should be in close association with a maternity hospital and that, to be really effective, it should be in the charge of obstetric specialists, or expert doctors, who are in daily contact with midwifery practice. The fact that the health visitor is seldom in direct touch with the antenatal clinic also detracts greatly from the real usefulness of her visit.

The chief sanitary inspector, Mr. A. W. Ritchie, draws attention to the failure of householders to see that their water cisterns are cleaned every six months. This raises the point that no householder ought to use Edinburgh's excellent water for drinking purposes after it has passed through a cistern, even if it is cleaned out every day and that each house should be supplied with at least one tap direct from the main for drinking and culinary purposes. Liverpool have special powers to enforce this.

Hull.

Dr. W. Allen Daley (whose appointment as divisional medical officer to the London County Council has recently been announced) reports that the year has been a busy one, in planning for the unification of the medical services of Kingston-upon-Hull, and preparing for important developments with respect to the establishment of the new isolation hospital, the extension of the city's boundaries, and the taking over of the medical work now done by the Guardians. The interavailability of the clinics has worked successfully. Thus there were 11,315 attendances of pre-school children and expectant and nursing mothers at the Education Committee's clinics, and 733 of school children, and 1096 of tuberculosis cases at the M. & C.W. light clinic. The East Hull clinic is to be erected on the site adjoining the East Tuberculosis Dispensary and will provide for East Hull all clinics and treatment supplied by the M. & C.W. and school medical departments. The various authorities have also adopted a scheme for the inter-change of their medical staff. Thus medical officers can be taken from routine work and turned on to emergency work. Again, during holidays, school medical officers can be given work in other departments. Assistance when needed will be furnished to the port medical officer, who on his side, will take part in administrative work. The new scheme, in fact, provides for the same doctors to work in the M. & C.W., school medical, tuberculosis, and other departments, and this will not only be good for the patients, but will save the officers from getting into watertight compartments and from having a limited outlook. Four of the senior staff will be primarily each in change of a department, while available for work in other departments These four seniors meet the medical officer of health once a month to discuss administrative matters, whilst evening meetings are held from time to time of the whole of the medical staff, numbering 25, for the reading of papers, discussions, &c. The new isolation hospital has made progress. The first four pavilions are completed and it will probably be opened about August, 1929, after which the existing hospital will be adapted for use as a maternity home and infants' hospital to accommodate 81 patients It is intended to make this new maternity home a model of efficiency. At the end of the year the privy conversion scheme was nearly completed, 38,050 out of 40,050 conversions having been completed and 614 unnecessary privies and pail-closets removed. The 1380 remaining privies and pail-closets are mostly in property which has to be demolished or in unsewered areas.

The municipal houses erected numbered 1008 in the suburbs and 12 tenements in the New George-street area, where further demolitions have been effected and another block of eight tenements and four lock-up shops is being erected. Two further improvement schemes will shortly be undertaken. Central heating on the Cookanheat system has been installed in 2650 municipal houses. There is considerable prejudice against central heating among those who are accustomed to coal fires. Complaints have been received that when sufficient heat is raised to warm the bedrooms, the living rooms become unbearably stuffy. A plebiscite among the tenants showed 30 per cent. for and 70 per cent. against central heating, but some of them have changed their minds as the result of six months' trial of the installation. The corporation now contemplate building houses with sash windows, instead of casement, as being more easily openable in bad weather, and they are also constructing open fire-places with the fire in one room and the oven in another. In order to remove grounds for complaint in the centrally heated houses, ventilators are to be fitted in the living rooms. In some cases the tenants have neutralised one of the advantages of the Cookanheat system by using coal instead of a smokeless fuel. The municipal building programme is being extended and probably 1500 houses and flats will be erected in 1929. In all present or future schemes bricks are being used in preference to concrete or other patent forms of construction. On the East Hull estate there were 40 parlour houses to let at the end of the year, but there is still a demand for parlour houses in North and West Hull and a vigorous demand for the smaller type of corporation house at all-in weekly rentals of 12*s.* 2*d.* and 13*s.* 6*d.* for two and three-bedroomed houses respectively. Dr. Daley points out, however, that the housing problem is not solved until houses have been erected at rentals which can be paid by families of five or six with incomes from £2 to £3 per week.

The Hull medical committee on cancer, at the suggestion of the Ministry of Health, is to investigate cancer of the breast, uterus and rectum. Lectures on the early diagnosis and treatment of cancer are given to medical men and women, and the committee are taking steps to secure an increased amount of radium for the treatment of cancer in the city. Hull like Edinburgh, recorded its lowest infantile mortality figure in 1928, and this in spite of a hot summer and an increase in the diarrhœa deaths. The hours of bright sunshine were 1339 in 1928, 1118 in 1927 and 1299 in 1926. Dr. Daley compares the diarrhœa deaths in 1928 with the hot summer of 1911, when infant welfare work was in an undeveloped condition. In 1928 there were 64 diarrhœa deaths under 1 year, 8 between 1 and 2 years, 2 between 2 and 5 years and 8 over 5, whereas in 1911 there were 423 under 1 year, 105 between 1 and 2, 26 between 2 and 5 and 64 at ages over 5. There was an outbreak of small-pox during the summer, which lasted until November and gave rise to 65 known cases. The outbreak began with a family which contracted the infection in a town in the West Riding. They had stayed during Whitsuntide in a house where there was supposed to be chicken-pox. The disease was very mild in character and there were no deaths. In most of the cases the onset was characterised by headache, dizziness and a feeling of "swimminess," associated with vomiting; backache was not a common feature, and in only four cases was sore-throat complained of. Dr. Daley gives full details and shows how the spread of infection was apparently helped by continuous desks in the schools. The infectivity of the disease was not nearly so great as that of small-pox of a generation ago. As the first cases had about four weeks' start of the intelligence department, the task of searching out new cases in order to restrict the outbreak was one of great magnitude. It is hoped to develop an anti-rheumatic centre in connexion with the medicinal baths. Dr. Daley points out that insured persons in Hull consumed 22 per cent. more medicine than the average for the area.

The reductase test has proved satisfactory as a preliminary bacteriological test for milk. Of 82 samples of "outside" milk examined for tubercle, eight or ten per cent. gave a positive result. In following up the eight positive cases, tuberculous cows were only discovered on three occasions. In the remainder the offending cows had probably been sold. An East Riding cow-keeper, who sent two tuberculous cows to a Hull slaughter-house, was fined £25 for failure to notify. A "urinary" enteric carrier, who was under observation in 1927, was to be considered free from infection if four consecutive negative tests were obtained; after three negative tests in August and September, the October sample proved positive and he is still under observation. It has been decided to erect an orthopædic hospital of 100 beds adjoining the sanatorium and isolation hospital at Cottingham. There is a striking reduction in the notifications of ophthalmia neonatorum during the last two years. During 1928 651 cases were admitted to the maternity home for confinement and there were no maternal deaths. Early induction of labour was needed for 37 of the cases, and 32 of the babies were discharged alive. Of the five infants who were lost, one was the baby of an epileptic, one of a patient suffering from severe albuminuria, one was macerated and two died of pemphigus neonatorum. About 25 per cent. of the expectant mothers attended a municipal antenatal clinic. Among the 1561 women who so attended, there were only two maternal deaths—i.e., one death for 780 confinements—whilst among those who did not attend a clinic, there was approximately one death for 197 confinements.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED JULY 27TH, 1929.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 129 (last week, 144); scarlet fever, 1764; diphtheria, 933; enteric fever, 58; pneumonia, 852; puerperal fever, 35; puerperal pyrexia, 97; cerebro-spinal fever, 12; acute poliomyelitis, 12; acute polio-encephalitis, 1; encephalitis lethargica, 20; dysentery, 4; and ophthalmia neonatorum, 120. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the Metropolitan Asylums Board on July 30th–31st was as follows:—Small-pox, 161 under treatment, 9 under observation (last week 173 and 3 respectively); scarlet fever, 1426; diphtheria, 1626; enteric fever, 12; measles, 317; whooping-cough, 339; puerperal fever, 25 (plus 12 babies); encephalitis lethargica, 123; "other diseases" 24. At St. Margaret's Hospital there were 15 babies (plus 9 mothers) with ophthalmia neonatorum.

Deaths.—In the aggregate of great towns, including London, there was 1 (1) death from small-pox, 3 (0) from enteric fever, 33 (5) from measles, 7 (3) from scarlet fever, 24 (5) from whooping-cough, 13 (2) from diphtheria, 44 (10) from diarrhœa and enteritis under two years, and 20 (3) from influenza. The figures in parentheses are those for London itself.

Liverpool reported 7 deaths from measles, and Manchester and Bradford 3 each. Liverpool also reported 5 deaths from diarrhœa and enteritis, and Manchester and Salford 3 each.

The number of stillbirths reported during the week was 244 (corresponding to a rate of 35 per 1000 births), including 34 in London.

British Dental Hospital.—The annual report of this institution, the primary object of which is the establishment of centres at which dental treatment is available for persons unable to pay for private treatment, shows that last year the number of patients' attendances was 19,426. There are nearly a score of treatment centres and clinics in various parts of London, some of them with maternity, tuberculosis, and children's departments; at the Lewisham L.C.C. school dental, minor ailments, and aural central clinic there were 4815 attendances. Arrangements are being made for the establishment of additional clinics, and for the treatment at reduced fees of adolescents between the ages of 16 and 21, who are ineligible for dental benefit. Adolescents between the ages of 14 and 16, who are not insured persons, are already provided for by the hospital.

EXHIBITION
OF
DRUGS, SURGICAL INSTRUMENTS, FOODS, AND APPLIANCES AT THE BRITISH MEDICAL ASSOCIATION MEETING.

THE exhibition in the City Exhibition Hall, Manchester, which was open from July 22nd to 26th, was unusually complete and well arranged and gave practitioners attending the annual meeting of the B.M.A. an opportunity of refreshing their memory of products and appliances new and old. Ample space was provided for the exhibits and in every case the attendants were ready with expert advice. It is impossible to do more than indicate some of the products which attracted attention.

DRUGS AND PHARMACEUTICAL PREPARATIONS.

1. *General Drug Exhibits.*

[12] and [35] Oppenheimer, Son and Co., Ltd. (179, Queen Victoria-street, E.C. 4), showed a series of preparations with the hall-mark "O.S. & Co.," including Roboleine and Vitad, the latter being the unsaponifiable fraction of cod-liver oil containing a high concentration of vitamins A and D, a palatinoid being equivalent to one-half or a whole teaspoonful of cod-liver oil.—[23] Bayer Products, Ltd. (10, St. Dunstan's-hill, E.C. 3), drew attention to a range of well-tested synthetic remedies including Adalin, Helmitol, Luminal, Phanodorm, and especially Avertin, a basal anæsthetic administered per rectum with advantages alike for surgeon, patient, and anæsthetist; also the Iso-double ampoule of Neo-salvarsan.—[33] The Saccharin Corporation, Ltd. (72, Oxford-street, W. 1), showed among their specialties Novocain, Glaucosan, Trivalin, and Causticin.—[36] Boots Pure Drug Co., Ltd. (Nottingham), had a large exhibit of fine chemicals and packed specialties including Sulphostab and Stabilarsan, an improved "914" for intramuscular injection, approved by the Ministry of Health. Bismostab contains a high concentration of metallic bismuth in isotonic glucose. Among other preparations Hexylresorcinol and Acriflavine were shown as well as Ephedrine and Insulin, at a present price to the patient of 1*s.* 8*d.* per 5 c.cm. ampoule of 100 units.—[48] Burroughs Wellcome and Co. (Snow Hill Buildings, E.C. 1) exhibited products resulting from recent scientific research and other preparations of outstanding importance in various branches of medicine, including micro-organism displays of scarlet fever, diphtheria, syphilis, influenza, pneumonia, leprosy, tuberculosis, and malaria. A number of plants selected from their Dartford farm reminded visitors that certain alkaloid-yielding plants can be cultivated to perfection in England.—[49] Sandoz Chemical Works (6, Wigmore-street, W. 1) had on view a new method of administering allium sativum and examples of Calcium-Sandoz, Sandoptal, Felamine, Femergin, Lobeline, and Scillaren.—[50] Schering, Ltd. (6, Lloyd's-avenue, E.C.3), called attention to Veramon as a safe and successful analgesic, Atophan, a popular uric acid eliminant, and Solganal, a new gold product of low toxicity for intravenous injection in tuberculosis and leprosy.—[61] and [62] Crookes Collosols (22, Chenies-street, W.C. 1) were showing original colloidal preparations for medicinal use with especial emphasis on Collosol Calcium, as employed in osteomalacia, tuberculosis, urticaria, and menorrhagia.—[67] Hoffmann-La Roche Chemical Works, Ltd. (51, Bowes-road, N. 13), over and above the well-known Omnopon total opium alkaloids, Sedobrol sedative bouillon, exhibited a tasteless non-toxic aperient known as Isacen with the composition diacetyl-di-hydroxy-phenyl-isatin. They also supply Thyroxin.—[70] Reynolds and Branson, Ltd. (Leeds), had on view a large series of elixirs, liquors, syrups, and tablets along with a vaccine for rheumatoid arthritis.—[71] May and Baker, Ltd. (Battersea, S.W. 11), commenced an exhibit with Novarsenobillon, Metarsenobillon, Metarseno-argenticum, running on through Stovarsol, Tryparsamide, and Stovaine to a series of vaccines and other remedies.—[73] Allen and Hanburys, Ltd. (48, Wigmore-street, W. 1), in addition to the various Allenburys foods and the "Byno" series of tonics, showed a number of "Polyglandin" preparations, as well as Insulin, Chrismol, liver products, and a selection of sera and vaccines prepared by the Lister Institute.—[76] Evans, Sons, Lescher, and Webb, Ltd. (60, Bartholomew-close, E.C. 1), demonstrated specialties manufactured at Liverpool and Runcorn. The biological products included Hepatex, a convenient form of liver extract for oral administration, Hæmex, and Infundibulin; among pharmaceutical specialties was Bi-drox, a stable form of hydrogen peroxide.—[85] Parke, Davis and Co. (50, Beak-street, W. 1) had on view many preparations manufactured at their Hounslow laboratories, including Metatone, Alophen pill, and Cascara evacuant. Their standardised cod-liver oil contains in each fluid ounce at least 18,500 units of vitamin A and 3000 units of vitamin D. Gland preparations included Estrogen, an extract of reproductive gland tissue, standardised in terms of rat units; also Pituitrin, Pitocin, Pitressin, and a preparation known as Thio-Bismol for intramuscular injection which being water- and tissue-fluid soluble is painless.—[91] Hough, Hoseason and Co., Ltd. (Bridge-street, Manchester), showed pharmaceutical specialties including elixirs of Formasal, Uralia, Lecitone, and Cardiotone.—[97] C. J. Hewlett and Son, Ltd. (35, Charlotte-street, E.C. 2), had a large exhibit of original preparations including Antiseptic cream, Liquor santal, Mist. pepsinæ co., Mist. damianæ co., and Hormonigen.—[99] British Drug Houses, Ltd. (City-road, N. 1), illustrated their pioneer work in the synthesis of vitamin D and the manufacture from natural sources of vitamins A and B, with an exhibit of Radiostol, Radiostoleum, and Radio-Malt. Other products shown were Acetylcholine, Liver Extract, Ephedrine, and Thyroxine.—[108] Lambert Pharmacal Co. (St. Louis, Mo. Agents: S. Maw, Son and Sons, 7–12, Aldersgate-street, E.C. 1) exhibited Listerine Brand antiseptic and demonstrated its germicidal action on various bacteriological cultures.

2. *Special Drug Exhibits.*

[11] Reed and Carnrick (Jersey City, U.S.A. Agents: Coates and Cooper, 41, Great Tower-street, E.C. 3) offered samples of such glandular preparations as Peptenzyme, Nephritin, Protonuclein, Pancrobilin, and Trophonine.—[30] Bristol-Myers Co. (112, Cheapside, E.C. 2) offered Sal Hepatica, Ipana tooth-paste, and Ziratol, a non-toxic hæmostatic antiseptic.—[31] J. F. Macfarlan and Co. (32, Bethnal Green-road, E. 1) exhibited Opoidine, a British preparation of alkaloids of opium, and catgut ligatures in glass tubes in American style, prepared according to Lister's and other formulæ.—[32] Anglo-American Oil Company, Ltd. (Camden Town, N.W. 1), had on view three well-established preparations: Nujol, an intestinal lubricant, Mistol, a combination of menthol, camphor eucalyptol, and chlorbutol for use in an atomiser, and Flit, a liquid insectide in spray form.—[53] Bemax Sales, Ltd. (7, St. James's-street, S.W. 1), called attention to a natural vitamin food and tonic in highly concentrated form. A month's supply of Bemax for an adult costs 2*s.* 6*d.*—[54] Fassett and Johnson, Ltd. (86, Clerkenwell-road, E.C. 1), besides Angier's Emulsion, Bemax, and Californian Syrup of Figs, showed a large range of Seabury and Johnson's plasters.—[58] Kaylene, Ltd. (7, Mandeville-place, W. 1), offered a colloidally reversible hydrated silicate of alumina of great purity and other combinations of Kaylene, as well as Colonol Liquid Paraffin.—[60] Scott and Turner, Ltd. (Gallowgate, Newcastle-on-Tyne), showed Andrews Liver Salt, a pleasant saline aperient with brisk effervescence, leaving a clear solution.—[61] and [65] Deshell Laboratories, Ltd. (Braydon-road, N. 16), offered the Petrolagar Brand Emulsion, for the treatment of intestinal stasis, containing 65 per cent. of pure medicinal paraffin

atomised by hydraulic pressure and held by an emulsion of agar-agar. Four different formulæ are available.—[77] and [78] Armour and Co., Ltd. (St. Martin's-le-Grand, E.C. 1), had an exhibit of preserved glands in natural colours and offered Glanoid medicinal products of animal origin with a special demonstration of liver products.—[89] C. R. Harker, Stagg and Morgan, Ltd. (London, E. 1), offered their entirely British Petrolax, an emulsion containing 65 per cent. pure liquid paraffin of high viscosity, combined with agar-agar and free from starchy matter.—[95] Virol, Ltd. (Hanger-lane, Ealing, W. 5), besides their special combination of marrow fat, malt extract, eggs, lemon syrup, salts of lime and iron, showed also Virolax, a liquid paraffin containing 40 per cent. of virol, recommended for use in intestinal toxæmia and the disorders arising therefrom.—[101] The Regulin Syndicate, Ltd. (W. Bredt, 41, Great Tower-street, E.C. 3), offered Regulin (Helfenberg) for the regulation of intestinal function, consisting of agar-agar with 3¼ per cent. extract of cascara; also Blutan, Pneumarol, and Valofin.

3. *Toilet Preparations.*

[57] Kolynos Inc. (Chenies-street, W.C. 1) presented their dental cream, containing antiseptic properties without grit, as well as a denture powder and a skin soap.—[88] The Pepsodent Co. (8, India-street, E.C. 3) offered a dentifrice with an acid reaction, due to the presence of fruit acids, and a polishing agent composed of tricalcium phosphate and calcium sulphate.

FOOD AND DRINK.

[5] H.A.G. Coffee Co., Ltd. (40, Theobalds-road, W.C. 1), demonstrated a caffein-free coffee, cleansed also of impurities such as wax, without affecting the flavour or aroma.—[9] Stower's (Alex. Riddle and Co., Ltd., Bancroft-road, E. 1) showed a lime-juice cordial, first introduced in 1862, with the newer concentrated unsweetened juice, as well as lemon- and orange-squashes.—[20] Montgomerie and Co., Ltd. (Ibrox, Glasgow), showed Berina foods for infants and invalids, and Bermaline bread.—[21] Saorstát Eireann (15, Regent-street, S.W. 1) had excellent samples of creamery butter, dried and condensed milk, honey, and eggs from the Irish Free State.—[25] Cow and Gate, Ltd. (Guildford), added to their usual display Lacidac, a lactic acid milk powder, and Hemolac, a milk food for the treatment of nutritional anæmia in infancy.—[27] Sister Laura's Infant and Invalid Food Co., Ltd. (Bishopbriggs, near Glasgow), invited the medical profession to sample a food to be used with fresh undiluted cow's milk. —[37] and [40] Nestlé and Anglo-Swiss Condensed Milk Co. (6, Eastcheap, E.C. 3), besides their standard milk, milk food, and pure thick cream, displayed Lactogen, a dried milk modified by the addition of lactose and made on modern principles.—[39] Ingram and Royle, Ltd. (45, Belvedere-road, S.E. 1), brought forward numerous imported mineral waters, including Vichy-Celestins, Contrexeville "Pavillon," Evian Cachat, Carlsbad, and Hunyadi János.—[51] Oxo, Ltd. (Thames House, Queen Street-place, E.C. 4), showed Oxo, Oxo Cubes, Hospital Oxo, and Lemco, along with three organic extracts Oxoid, Liveroid, and Splenoid.—[56] Maison Ackerman-Laurance (St. Hilaire-street, Florent, near Saumur, France) gave special prominence to their exhibit of sparkling Saumurs, whilst on the same stand Messrs. Francesco Cinzano (Turin) exhibited their Italian vermouth.—[59] Energen Foods Co., Ltd. (Willesden, N.W. 10), showed the Energen bread and other foods, originally prepared for diabetic patients, now designed for the dietary of other metabolic disorders; also a series of Energen cereals.—[79] Vitalia, Ltd. (17A, Boniface-street, Westminster Bridge-road, S.E. 1), called attention to a meat juice prepared by a cold process which retains the natural vitamins and organic salts.—[90] Benger's Food had its usual display jars, showing the special features of the food, along with other products such as Liquor pancreaticus, Liquor pepticus, and Liquor thyroidin.—[92] Plasmon, Ltd. (66A, Farringdon-street, E.C. 4), called attention to an analysis of Plasmona, a concentrated and easily assimilable food preparation containing lipoid, liver, and protein components; also to Splenex, a pure extract from the spleen of the calf.—[94] Cadbury Brothers, Ltd. (Bournville), gave free sample cups of Bournville cocoa and showed other interesting products of the chocolate industry.—[102] Hovis, Ltd. (Macclesfield), demonstrated the processes used in manufacturing their well-known flour and offered samples for tasting.—[105] Frank Cooper, Ltd. (Victoria Buildings, Oxford), described the manufacture of "Oxford" marmalade and fresh fruit preserves.—[107] Jewsbury and Brown, Ltd., exhibited their Citoda water, a special soda water for medical purposes. They supply non-alcoholic wines and cordials.—[113] William Gaymer and Son, Ltd. (Attleborough and London), had their usual exhibit of dry cyder made from English apples.

SURGICAL INSTRUMENTS.

[6] Charles F. Thackray (Park-street, Leeds) had a compendious exhibit of instruments for abdominal and general surgery, with equipment of modern design for operating units.—[17] London Surgical Supply Co. (45, Church-road, N. 1) displayed a fine series of cystoscopes, sigmoidoscopes, urethroscopes, and bronchoscopes with a special collection of genito-urinary instruments, a large proportion of them being of stainless steel.—[22] Albert Browne, Ltd. (Chancery-street, Leicester), demonstrated Freund's new hysteroscope for detecting placental remains, and Zeiss's Evacuator for removal of fragments of stone under optical vision.—[24] Arnold and Sons (John Bell and Croyden, 50, Wigmore-street, W. 1) had on view every form of surgical equipment including their pedestal operation table on an oil-pump base, electrical instrument sterilisers, French's venesection apparatus, special syringes for varicose vein injection, and a series of ligatures and sutures subjected to strict bacteriological tests in their own laboratories.—[26] John Weiss and Son, Ltd. (287, Oxford-street, W. 1), displayed several new additions to their range of ophthalmic instruments and appliances, as well as equipment for the general surgeon, such as Robert Jones's bone instruments, Harrison's urethroscope, Putti's tourniquet, and Wilfred Harris's needles for trigeminal injection.—[28], [29], and [45] Mayer and Phelps (50, New Cavendish-street, W. 1) had a large selection of instruments and apparatus of original design for general and regional surgery, many in stainless steel. Popper's hæmostatic guillotine, an ingenious device crushing with 200 lb. pressure, and Lambert Rogers's skull plough with protective guard for the dura deserve special mention.—[41] F. C. Rein and Son (30, Charing Cross-road, W.C. 2) displayed their Diatonic Audiometer and an advanced type of hearing device known as the Viteron Compensator Model.—[47] Down Brothers, Ltd. (21, St. Thomas's-street, S.E. 1), had an exhibit covering the whole field of general and special surgery including Souttar's craniotomy instruments, Sinclair's instruments for fractures, Lane Joynt's skin-grafting instruments, Reavell Moseley electric suction apparatus, and much else.—[66] General Acoustics, Ltd. (77, Wigmore-street, W. 1), displayed Acousticon aids for the deaf with 50 different electrical types, each of which can be regulated in 110 degrees of volume.—[68] J. Gardner and Son (22, Teviot-place, Edinburgh) included in a comprehensive selection of instruments Fraser's laminotomy forceps, Wilkie's abduction splint, Douglas Guthrie's retractor and tongue forceps, and many others.—[72] Allen and Hanburys, Ltd. (48, Wigmore-street, W. 1), had on view the St. Bartholomew's Hospital latest model operation table with self-locking device and head clamp, instrument cabinets and tables in non-corrodible metal, and instruments for the introduction of radium needles and radon seeds.—[75] The Holborn Surgical Instrument Co., Ltd. (20, Thavies Inn,

E.C. 1), showed chrome-plated surgical instruments of all descriptions with electric diagnostic outfits and other devices.—[84] Billings and Sons, Ltd. (305, Oxford-road, Manchester), offered a number of improvements in surgical instruments and appliances such as Eve's Halometer, Wrigley's tonsil guillotine, Sankey's warm ether vapour apparatus, and Scannel's new apparatus for whole blood transfusion.—[90] R. H. Dent (309, Oxford-street, W. 1) displayed the latest models of the Ardente range of hearing aids.—[106] The Genito-Urinary Manufacturing Co., Ltd. (28A, Devonshire-street, W. 1), showed a range of special instruments, cystoscopes, lithotrites, and instruments for the application of radium.—[114] James Woolley, Sons and Co., Ltd. (Manchester), besides a large exhibit of galenicals, also showed surgeons' bags, stainless steel surgical instruments, blood transfusion apparatus, sterilisers, and syringes.

SURGICAL AIDS: HOSPITAL AND LABORATORY EQUIPMENT.

[2] The Dowsing Radiant Heat Co., Ltd. (91, Baker-street, W. 1), illustrated many medical applications of heat including the Ultradescent Luminous Heat Ray Appliance with vita-glass bulb. Their Subaqueous Bath fittings permit of airtight and watertight colonic irrigation free of smell.—[4] Restiform Specialities, Ltd. (Pembroke-place, Liverpool), demonstrated a hospital bed so constructed that the patient merely by his own movement can at will adjust the angle at which he is lying through seven positions. —[8] Whitfield's Bedsteads, Ltd. (109, Watery-lane, Bordesley, Birmingham), had a selection of "Lawson Tait" bedsteads and a special bed-lifter.—[14] Campoirette, Ltd. (252, Regent-street, W. 1), showed the Camp Physiological Supports for abdominal treatment.—[15] Antiphlogistine was displayed as the best-known method for the continuous application of moist heat. By osmosis and cutaneous stimulation it maintains the circulation and aids in eliminating toxins.—[10] Short and Mason, Ltd. (Macdonald-road, Walthamstow, E. 17), exhibited a series of accurately calibrated "Tycos" instruments—sphygmomanometer, thermograph, micro-barograph—as well as urinalysis glassware.—[34] Holophane, Ltd. (Elverton-street, S.W. 1), demonstrated the transmission by ultra-violet rays of Holviglass, which is colourless, permanent, and stronger than ordinary glass.—[42] Ronuk, Ltd. (Portslade, Sussex, and 16, South Molton-street, W. 1), showed their floor polish and preservative stain, together with weighted polishing brushes suitable for hospitals.—[43] Cambridge Instrument Co., Ltd. (45, Grosvenor-place, S.W. 1), laid emphasis on their Portable Electrocardiograph which weighs in all 110 lb. and has most of the virtues of the standard pattern.—[40] Chas. Hearson and Co., Ltd. (24, Fenchurch-street, E.C. 3), had a display of Research Apparatus, pathological, biological, bacteriological, and biochemical, and a good selection of well-known makes of microscope, and were demonstrating Venules.—[52] The Inhaling Drug and Apparatus Co., Ltd. (Windsor House, Victoria-street, S.W. 1), showed the Spiess-Drager apparatus for nebulising various medicaments in a current of oxygen, the diameter of the particles being in the neighbourhood of 10 μ.—[63] H. E. Curtis and Son, Ltd. (7, Mandeville-place, Wigmore-street, W. 1), exhibited their devices for securing the support of ptosed organs and various forms of hernia.—[74] J. Nesbit-Evans and Co. (Wednesbury, Staffs.) showed many kinds of bedstead, including the "Anti-accident" children's cot and the "Hey-Groves" Special orthopædic bedstead.—[81] and [82] The "Vita" Glass Marketing Board (Aldwych House, W.C. 2), describing their product as the only British window glass admitting the natural health-giving rays of sunlight, announced that already over 100 schools and nearly 200 hospitals have been fitted with it.—[98] Spencer Corsets, Ltd. (Banbury, Oxon., and 96, Regent-street, W. 1), had a variety of surgical supports and garments including a corset for the treatment of sacro-iliac strain.—[108] The Condensed Gas Co., Ltd. (171A, Oxford-road, Manchester), showed their novel "Titan-Ese" control valve for gas cylinders which is designed to eliminate all need for elaborate gas stands incorporating fine-adjustment devices. They offered facilities for making apparatus to the purchaser's design.—[112] Theodore Hamblin, Ltd. (15, Wigmore-street, W. 1), set out a large number of ophthalmological instruments and aids—among them the New Lister Morton ophthalmoscope, a convenient Harrison Butler hand slit-lamp, and a tubular resistance for using ophthalmoscopes from the main current. They also showed Speclettes, which are folding spectacles for the pocket.—[115] Kodak, Ltd. (Kingsway, W.C. 2), exhibited X ray negatives on "Dupli-tised" X ray film, together with dental film negatives and cinematographic apparatus and accessories for clinical photography.—[117] Philips Lamps, Ltd. (145, Charing Cross-road, W.C. 2), showed their "Metalix-Portable" X ray apparatus, which can be worked from any electric light socket. Among X ray tubes on view was a deep therapy tube, Type F, for operation at 220,000 volts and a miniature tube for skin therapy by the Bucky method.—[118] Messrs. Schall and Son, Ltd. (75, New Cavendish-street, W. 1), displayed a selection of the X ray and electro-medical apparatus which in their experience is most popular for cottage hospitals and general practice. Their Diathermy Special Surgical Model supplies a cutting current and is designed for the use of surgeons employing the electro-surgical technique described by Harvey Cushing and Wyeth. —[119] Hoskins and Sewell, Ltd. (Bordesley, Birmingham), drew attention to devices by which their hospital bedsteads have lately been improved. They showed a wheeling ward screen and a "Luxor" adjustable bedstead which can be used in seven different positions.

MISCELLANEOUS.

[1] The Medical Insurance Agency (B.M.A. House, Tavistock-square, W.C. 1) offered evidence of its expanding work and of the benefits obtainable by insuring persons or property under its auspices. Grants made to medical and other charities now amount to £22,980.—[44] The Food Education Society (29, Gordon-square, W.C. 1) described its work in arranging lectures and cookery demonstrations, and exhibited useful publications on dietetics and hygiene.—[55] The British Medical Bureau (12, Stratford-place, W. 1) set out advantageous terms on which it assists in the transference of practices and makes arrangements for locum tenents, resident patients, and accountancy.—[69] The Medical Sickness, Annuity and Life Assurance Society, Ltd. (300, High Holborn, W.C. 1), drew attention to their liberal sickness, accident, life, educational, and partnership assurance policies. The Society is now prepared to lend money for house purchase.—[83] The Hot Springs of Bath had an exhibit illustrating their manifold amenities, and [100] Harrogate called special attention to the systematic training of the staff of its bathing establishments.

Many of the principal medical publishers displayed copies of their new books and new editions.

HOSPITAL COÖRDINATION AT BRISTOL.—The Bristol Hospitals Representation Committee, which has been considering the best means of coördinating the work of the city's hospitals and medical institutions, has recommended the creation of a hospitals council. It is suggested that the functions of this body should be to collect and publish information as to the hospital needs of the area, the sufficiency of beds and finance, to prevent overlapping, to consider and criticise proposed extensions of existing and the erection of new hospitals, and to propose and advocate such extensions and erections. The scheme has been endorsed by the council of the Lord Mayor's Hospital Committee at a meeting at which Dr. R. A. Askins, the medical officer of health, stated that the Bristol hospitals were in some respects overlapping, and in others competing or not meeting the public demand.

Correspondence.

"Audi alteram partem."

AURAL DISEASE AND BATHING.

To the Editor of THE LANCET.

SIR,—In answer to the inquiry by "F.R.C.P." as to the "special measures to prevent excessive contamination of swimming baths," it may be stated that the system of continuous filtration, disinfection, and aeration provided by the various types of special plant installed for that purpose in a large number of the public baths in London and the provinces has gone far to meet the need for counteracting their pollution, as well as the call for economising the water-supply. Additional precautions, including the direct supervision of bathers before entering the bath, and attention to details of their personal cleanliness, such as are reported to be stringently applied in the United States, though affording further safeguard against risk of contamination, are probably considered too exacting for application in this country and likely to be strongly resented by the British bathing public. It is true that evidence as to the presence or absence of the *B. coli* group is regarded as supplying a convenient standard of bacterial pollution, in addition to the enumeration of the total organisms per c.cm. The standard recommended by the American Public Health Association is that they should not yield more than 1000 organisms per c.cm. after 24 hours' incubation at 37° C. in over 10 per cent. of samples of swimming bath water, with no single count of more than 5000 per c.cm., and the presence of *B. coli* in not more than two out of five samples of 10 c.cm. of water taken on the same day. Unless special investigations are required, particular attention is not usually paid to streptococcal contamination as a routine, although there is little doubt that its presence can be detected without difficulty in subculture tests from the primary plate cultures. As an example may be quoted a qualitative analysis,[1] made some years ago, of water from a small covered swimming bath, detailing the various organisms identified in an approximate count of 4000 colonies per c.cm. Subcultures from a number of scattered colonies showed that over 50 per cent. belonged to the proteus and *B. coli* groups, 12 per cent. were *Staphylococcus pyogenes aureus*, and 4 per cent. *Streptococcus fæcalis*, in addition to a similar proportion of a Gram-negative diplococcus (possibly *Micrococcus catarrhalis*), *Staphylococcus albus*, and *Sarcina lutea*. Chemical analysis also is helpful in affording evidence of degrees of pollution, and, especially when chlorination is used for disinfection, the estimation of the amount of available free chlorine, on account of its bactericidal action, can and should be regularly carried out by simple test, or by the use of the chloroscope, to ascertain that the necessary 0·2 parts per million free Cl is maintained.

The question of the prevention of pollution of swimming baths formed the subject of a detailed discussion at a meeting of the Medical Officers of Schools Association[2] in May, 1927, and was fully reported in the Association's annual report for that year. It is significant that, as compared with the attention paid to the safeguarding of the general public, precautions to ensure the hygienic condition of swimming baths in the great majority of our private and public schools leave much to be desired.

I am, Sir, yours faithfully,

August 3rd, 1929. J. GRAHAM FORBES.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Comdr. A. B. Cox is placed on the Retd. List with rank of Surg. Capt.

ROYAL NAVAL VOLUNTEER RESERVE.

Surg. Sub.-Lt. E. H. Parkinson to be Surg. Lieut.

Proby. Surg. Lt. (D) W. R. Young to be Surg. Lt. (D).

The King has approved of the award of the Royal Naval Volunteer Reserve Officers' Decoration to Surg. Lt.-Comdr. J. Lorimer.

ROYAL ARMY MEDICAL CORPS.

Maj. W. B. Laird retires, receiving a gratuity.

Maj. T. H. Dickson retires on ret. pay.

Lts. G. Anderson, R. J. G. Hyde, and R. V. Franklin to be Capts.

ARMY DENTAL CORPS.

Capt. A. V. Milnes to be Maj.

ARMY RESERVE OF OFFICERS.

Army Dental Corps: H. Wade, late Capt., Ind. Army, to be Capt.

TERRITORIAL ARMY.

Lt. G. W. Robinson to be Capt.

S. Newsom to be Lt.

Capt. G. F. Wilson, having attained the age limit, relinquishes his commn.

Capt. Alexander Graham Bryce (late R.A.M.C.) to be Capt.

Capt. D. Stewart, from T.A. Res. of Off. (4th/5th Bn. R. Scots), to be Lt.

Lt. R. E. Rees (late 6th Bn. R.W. Fus.) to be Lt.

Supernumerary for service with O.T.C.—A. J. Parer to be Lt., supern. for serv. with Med. Unit, Univ. of London Contgt., Sen. Div., O.T.C.

TERRITORIAL ARMY RESERVE OF OFFICERS.

Lt. E. L. Hanc [illegible], from the Active List, to be Lt.

RESERVE OF AIR FORCE OFFICERS.

E. J. Mockler resigns his permanent commn. in the Royal Air Force and is granted a commission as a Flight Lt., Class D.i.

INDIAN MEDICAL SERVICE.

Lt. Mohan Lal Ahuja to be Capt.

Lt. (on prob.) F. W. H. Caughey to be Capt. (prov.) (on prob.).

Parliamentary Intelligence.

HOUSE OF COMMONS.

WEDNESDAY, JULY 24TH.

Grinding Wheel Closed at Sheffield.

Mr. HOFFMAN asked the Home Secretary whether his attention had been drawn to the closing of the Corporation-street grinding wheel in Sheffield, which had thrown out of employment 40 to 50 men; and what was the reason for this step taken by the factory inspector.—Mr. CLYNES replied: It is reported to me that the conditions at these premises have been very unsatisfactory, and in particular that some of the most important provisions of the Regulations for the grinding of cutlery and edge tools are not complied with. This Code of Regulations was made as long ago as 1925 to protect the workpeople from the grave danger of silicosis of the lungs; a period of three years was allowed before some of the Regulations became operative, so as to give owners and occupiers of premises an opportunity of making any necessary alterations in the ventilating and other arrangements, but notwithstanding this and repeated warnings from the factory inspector since January last, the owners of the property have not found themselves able to bring it into compliance with the law. In these circumstances the inspector came to the conclusion, which I think was fully justified, that he could not acquiesce in work being continued under these unsatisfactory conditions until the premises were put in order. I am glad to say, however, that the hon. Member would appear to have been misinformed as to the number of persons likely to be thrown out of employment; the inspector reports not only that the number working there has been much smaller than 40, but that most of these are obtaining, or have obtained, places elsewhere, and that so far as he can judge only three or four are still seeking places.

[2] See THE LANCET, 1927, i., 1143.

THURSDAY, JULY 25TH.

Nursery Schools.

Lady CYNTHIA MOSLEY asked the President of the Board of Education whether he could state plans for the more general extension of nursery schools; and whether he proposed to ask for powers to require local authorities to establish nursery schools in their areas.—Sir CHARLES TREVELYAN replied: I am considering the best way of securing an extension of nursery schools, but I cannot make any definite statement before the House rises for the recess.

Contagious Abortion and Malta Fever.

Mr. GUINNESS asked the Minister of Agriculture whether his attention had been drawn to evidence recently published connecting outbreaks of undulant or Malta fever in human beings with the consumption of milk from cattle suffering from contagious abortion; and whether he would take any action to clear this matter up, either by veterinary research or in conjunction with the Medical Research Council.—Mr. BUXTON replied: I understand that the Ministry of Health will shortly issue a report containing the evidence, mainly obtained abroad, on which is based the theory that a form of undulant fever is caused by the bacillus which produces abortion in animals. The publication of this comprehensive report will attract the attention of medical and veterinary practitioners and research workers to the study of this question on which so far as this country is concerned there is at present very little information.

Hospitals and Motor Accidents.

Mr. LOUIS SMITH asked the Minister of Transport whether, in view of the accumulation of accidents directly or indirectly due to motor traffic which had to be treated in the hospitals of the country, often to the exclusion of local patients, he would investigate the possibility of legislation aimed at permitting such hospitals to recover expenses as in the analagous case provided by Section 16 of the Local Government Act, 1929, or by some earmarked addition for the benefit of the hospitals to the statutory motor licence or driver's licence.—Mr. HERBERT MORRISON replied: I am advised that Section 16 of the Local Government Act, 1929, applies to hospitals maintained by local authorities. I do not think that it would be practicable to apply similar provisions to other hospitals or to impose an additional statutory charge for drivers' licences with a view to dividing the proceeds among them.

Manufacture of Vaccine Lymph.

Mr. GROVES asked the Minister of Health if he would supply particulars of the various changes which had been made in the manufacture of vaccine lymph issued by his department since the system of public arm-to-arm vaccination was abandoned.—Mr. GREENWOOD replied: My hon. friend will find a full statement on the technique and procedure adopted in the preparation of vaccine lymph in the Report of the Vaccination Committee, 1928, pp. 16–17.

Vaccination.

Mr. BROAD asked the Minister of Health whether he was prepared to guarantee that any child or person vaccinated with Government lymph would not be seriously injured by the operation; and, if it was not possible, whether he would consider the desirability of introducing legislation to secure that compensation should be given in such cases to the parents or dependents, as the case might be.—Mr. GREENWOOD replied: It is impossible to give an absolute guarantee that no person vaccinated with Government, or any other, lymph will suffer injury, but I may point out that the lymph produced by the Government Lymph Establishment complies in all respects with the standards laid down in the regulations made under the Therapeutic Substances Act. As regards the second part of the question, as at present advised, I could not undertake to introduce legislation on this subject.

Mr. BROAD asked the Minister of Health when rabbits first began to be used in the production of Government lymph supplies; whether any cases of post-vaccinal encephalitis were reported in this country prior to such introduction of rabbits; and whether his medical advisers had considered the desirability of dispensing with the use of rabbits for the purpose in question.—Mr. GREENWOOD replied: Rabbits have been systematically used for this purpose since 1902. No case of post-vaccinal encephalitis was reported in this country until December, 1922. As regards the last part of the question, the desirability of dispensing with the use of rabbits has been considered, but it was not deemed necessary to recommend any change in the present practice.

Pollution of the River Lea.

Major CHURCH asked the Minister of Health whether he was aware that the River Lea from Tottenham lock downwards through the districts of Hackney and Homerton was, and had for many years been, in a foul condition; and whether, as this stretch of the river was a menace to the health of residents near its banks, he would take steps to ensure that the river was restored to a reasonable standard of purity.—Mr. GREENWOOD replied: Several large schemes of sewerage and sewage disposal have been carried out at heavy cost in recent years by local authorities with a view to improving the condition of the river. I am arranging for a visit of inspection in the near future.

Report on River Pollution.

Rear-Admiral BEAMISH asked the Minister of Agriculture whether the report of the Standing Committee on River Pollution, which the Ministry undertook to issue after a decision reached in February, 1928, could now be issued.—Mr. BUXTON replied: The preparation of this report involves an analysis of a large number of river surveys. I anticipate that the draft report will be ready for the consideration of the Standing Committee in the autumn, and the review of river surveys will include those carried out in 1928.

Water Supplies.

Sir WILLIAM DAVISON asked the Minister of Health whether, in view of the menace to the health of London through an impending shortage of water in London, he would make an inquiry as to the amount of water available; and what, if any, restrictions in the use of water were immediately required or contemplated.—Mr. GREENWOOD replied: I am assured that no serious shortage of water in London is to be expected, because of the large storage capacity which has been provided by the Metropolitan Water Board. The restrictions now in force have been imposed because of the very large increase in consumption and to prevent possible difficulties of distribution in certain areas. I understand that no further restrictions are contemplated.

Removal of Panel Practitioners.

Mr. DAY asked the Minister of Health whether he could give the reasons for the removal of the 46 insurance practitioners who had been removed from the medical list since 1918.—Mr. GREENWOOD replied: The reason in each case was that the Minister was satisfied after the prescribed inquiry that the continued inclusion of the practitioner in the medical list would be prejudicial to the efficiency of the medical service of the insured.

War Pensioners and Tuberculosis.

Mr. DAY asked the Minister of Pensions the number of war pensioners suffering from tuberculosis who were at present receiving treatment in sanatoria, and the number of such cases that were in sanatoria attached to a village settlement.—Mr. F. O. ROBERTS replied: The total number of pensioners at present receiving treatment in sanatoria is 1044, of whom, so far as can be ascertained, 68 are in sanatoria attached to village settlements.

Food Council and Milk Prices.

Mr. WISE asked the President of the Board of Trade what was the view of the Food Council concerning the 60 per cent. to 100 per cent. margin over the farmers' prices to be charged by the milk combine and other distributors under the scheme now under consideration; and what he proposed to do.—Mr. W. GRAHAM replied: The scheme under consideration is a complicated one, designed to apply to the milk trade throughout both England and Wales. The Food Council consider it necessary to consult the associations of milk distributors in order to have the details more clearly before them, and the matter will accordingly be discussed with those associations as soon as practicable. The scheme, if approved, would not in any case come into force until Oct. 1st.

All-India Medical Council.

Major GRAHAM POLE asked the Secretary of State for India if the Government of India had made any progress towards the establishment of an All-India Medical Council; and why no steps had been taken to appoint a government commissioner of medical qualifications and standards despite the fact that this appointment was provided for in the existing law and had been approved in principle by the central and provincial governments.—Mr. BENN replied: The Government of India recently convened a conference of representatives of provincial governments to consider the proposal to create an All-India Medical Council. I have not yet received a report of the conference. I hope to be able shortly to make an announcement regarding the appointment of a Commissioner of Medical Qualifications and Standards.

Removal of Trade Refuse.

Sir GEORGE HAMILTON asked the Minister of Health whether, in view of the divergence of opinion as to the correct definition of trade refuse, he would consider the question of amending Section 42 of the Public Health Act, 1875, and Section 48 of the Public Health Acts (Amendment) Act, 1907, to permit a local authority to treat refuse from shops under the same heading as house refuse and to collect it without charge, thus altering the present situation whereby the refuse from one shop was house refuse and from another shop trade refuse.—Mr. GREENWOOD replied: This matter has already been noted for consideration when an opportunity occurs to amend the Public Health Acts.

Eyesight Injuries in Engineering Workshops.

Mr. JAMES WILSON asked the Home Secretary whether he was aware of the injury caused to the eyesight of employees in engineering workshops through the lodgment of foreign matter in the eye; and whether he would make arrangements for the appointment of an eye specialist in engineering towns, at which such employees could receive treatment on production of their medical card.—Mr. CLYNES replied: I am aware of the liability to eye injuries in many engineering processes, and the first-aid arrangements which are required to be made at every factory provide for the first-aid treatment of these injuries. Arrangements, however, for the provision of any specialist treatment which may be necessary subsequently are outside the scope of the Factory Acts, and all I can offer is to bring the hon. Member's suggestion to the notice of my right hon. friend, the Minister of Health.

Health of Metropolitan Police Constables.

Lieut.-Colonel HENEAGE asked the Home Secretary the hours of employment of police constables of the Metropolitan police on traffic duty; and the number of cases of illness or overstrain which had resulted from these hours.—Mr. CLYNES replied: The duty period is eight hours with a break of half an hour for refreshments. I am informed that there is no evidence of cases of illness or overstrain resulting from the length of the duty period.

Miners and Anthracosis.

Mr. HOPKIN asked the Secretary for Mines if he would assure miners who suffered from anthracosis that they would have compensation at least to the same extent as those who suffered from silicosis and under the same conditions.—Mr. CLYNES replied: By anthracosis I understand the hon. Member to mean the blackened condition of the lungs which is sometimes caused by inhalation, over a considerable period, of coal dust. I have at present no evidence that this condition disables the workman, but an inquiry is in progress under the direction of the Health Advisory Committee of the Mines Department, and the matter will be further considered when the results of this inquiry are available.

THE LATE DR. STANLEY BOTT.

WE have already recorded the death of Dr. Stanley Bott, at the age of 50, after a long period of indifferent health. He was a student of the London Hospital, which he entered in 1900. Qualifying as M.R.C.S. five years later he visited Australia as a ship's surgeon, and then undertook a series of house appointments at Dorchester, Reading, and finally at the Westminster Hospital, where he was resident obstetric officer. With this experience behind him he took over a practice at Caistor in Lincolnshire, in a scattered agricultural district. He had few interests outside his work, on which he was extremely keen, and though a somewhat reserved nature prevented his making many friends, his services were deeply appreciated by patients, whilst his knowledge and solid virtues were appreciated by his colleagues. In 1921, Dr. Bott took the M.D. degree of Durham University. During the war, however, he had been over-burdened by extra duties, and in 1923 he had a serious breakdown in health, and was obliged to give up his professional activities. For the past year or two he had been living at Broadstairs. He leaves a widow.

Medical News.

ROYAL COLLEGE OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND.—As the result of the Final Examination, held from July 1st to 24th, the following candidates were approved in the undermentioned subjects, but are not eligible for the diplomas of the Colleges:—

Medicine.—S. Ahmad, Punjab and London; H. S. Atkinson, London; G. O. Barber, Cambridge and St. Mary's; J. E. L. Bendor-Samuel, London; J. H. Bentley, Univ. Coll.; J. G. Bowen, London; G. G. Cameron, Guy's; A. Caplan, St. Bart.'s; G. J. Clarke, Guy's; H. O. Clarke, Dublin; H. W. Davies, King's Coll.; L. Farris, Liverpool and Charing Cross; Doreen P. Firmin, Cambridge and Westminster; J. F. Fisher, St. Bart.'s; A. M. Fratel, Newcastle-on-Tyne; H. S. H. Gilmer, St. George's; R. McN. Glover, Westminster; P. E. Glynn, Leeds; M. B. W. Gray, London; A. Guirdham, Oxford and Charing Cross; Verna Hackett, Westminster; Kathleen M. L. Hall, Royal Free; Cicely L. Hingston, St. Mary's; Mary A. Hughes, Charing Cross; Eugenie C. Illingworth, Leeds; K. S. Keele, Guy's; N. F. Kendall, St. Bart.'s; Mary L. R. Kennard, St. Mary's; E. J. Kerr, Birmingham; A. H. Lendon, Adelaide; A. Lister, London; W. D. Lovelock-Jones, Cardiff and Univ. Coll.; H. S. A. Malik, St. Thomas's; F. N. Marshall, Manchester; P. H. Merlin, Birmingham; Ruth Milne, Royal Free; C. W. Morley, Cambridge and St. Mary's; J. N. O'Reilly, Middlesex; I. E. Phelps, St. Bart.'s; N. L. Price, Bristol; D. S. Raju, Guy's; C. R. Salkeld, St. Thomas's; L. Savronsky, London; S. Scher, Univ. Coll.; K. M. Seedat, Bombay and Charing Cross; Violet R. Sharp, Royal Free; G. C. Sheldon, King's Coll.; C. H. Sherwood, Birmingham; T. Singh, Punjab and Charing Cross; L. A. H. Snowball, King's Coll.; H. J. Stracey, St. Thomas's; J. M. Thomas, Cardiff and Univ. Coll.; V. Thorne-Thorne, Cambridge and St. Bart.'s; and Eileen A. L. Webb, Royal Free.

Surgery.—S. G. Allen, London; G. H. Bateman, King's Coll.; T. S. Belcher, J. E. L. Bendor-Samuel, and J. G. Bowen, London; W. D. Brown, Cambridge and London; P. C. Chakravorty, Middlesex; Rosa E. Chamings, Royal Free; J. L. Clapham, St. Thomas's; A. H. Clegg, Leeds; S. C. S. Cooke, Middlesex; H. D. Cronyn, St. Mary's; T. Davies, St. Bart.'s; N. R. Donald, Liverpool; A. N. Duggal, Lahore; R. M. Ealand, Bristol; A. Eckford, Guy's; L. Gabbé, Cape and Guy's; R. M. Glover, Cambridge and Westminster; P. E. Glynn, Leeds; M. B. W. Gray, London; A. H. Gurney, Cambridge and St. Bart.'s; Y. A. A. Hammouda, Cairo and St. George's; R. D. Harding, King's Coll.; C. C. Harvey, Cardiff and Univ. Coll.; E. Harvey, Middlesex; Columba M. D. Heathcote, Charing Cross; C. F. Hecker, Adelaide and London; L. Hershfield, Middlesex; P. Y. Hicks, St. Thomas's; H. B. Jackson, Middlesex; W. D. G. James, Cardiff and St. Mary's; J. L. Jekyll, Cambridge and London; H. Y. Khwaja, London; A. H. Lendon, Adelaide; E. L. Littler and R. W. McConnel, King's Coll.; G. K. McKee, St. Bart.'s; E. J. Mann, Birmingham; E. Marks, St. Mary's; Eileen M. Massey, King's Coll.; E. C. W. Maxwell, St. Thomas's; F. C. Mayo, King's Coll.; P. H. Merlin, Birmingham; L. B. Neel, St. George's; J. E. Newton, Bristol; J. N. O'Reilly, Middlesex; A. P. M. Page, St. Bart.'s; B. W. Paine, Univ. Coll.; L. H. Peiris, Ceylon and King's Coll.; J. Petro, St. George's; J. R. F. Popplewell, Guy's; N. L. Price, Bristol; H. Ramsay and J. Richardson, Middlesex; N. D. Sane and L. Savronsky, London; J. G. Scadding, Middlesex; S. Scher, Cape and Univ. Coll.; D. P. Settna, London; T. M. Spilhaus, St. Thomas's; H. H. L. Spitz, Leipzig and Middlesex; R. Stanley, N. Stevens, and H. J. Stracey, St. Thomas's; A. Taylor, Manchester; D. M. Thomas, Cardiff and Middlesex; E. G. Thomas, Univ. Coll.; K. S. Thompson, London; T. F. Tierney, St. Bart.'s; C. Wall, London; E. M. Ward, St. Bart.'s; V. W. L. Wells, Guy's; L. H. Wharton, Bristol; A. J. White, Middlesex; E. R. Willis and B. Yuill, London.

Midwifery.—W. Addey, Manchester; A. M. M. M. Ali, Middlesex; J. E. G. Baker, London; J. C. Banerjea, Calcutta; A. Barber, St. Bart.'s; G. O. Barber, Cambridge and St. Mary's; J. H. Bartlett, St. Mary's; F. Bartholomew, St. Thomas's; A. K. Basu and J. H. Bentley, Univ. Coll.; M. V. Bhajekar, Middlesex; I. Billig, St. Thomas's; S. Bochenek, St. Bart.'s; C. C. Bryson, Cambridge and Middlesex; D. R. Buchan, Birmingham; A. Burkhardt, Univ. Coll.; C. L. Carter, St. Bart.'s; H. M. Chappel, Univ. Coll.; F. W. Chippindale, Guy's; L. P. Clarke, St. George's; A. F. H. Coke, St. Mary's; H. Coorland, St. Bart.'s; W. H. Croft, Birmingham; T. Davies and A. F. Davy, St. Bart.'s; A. L. Devi, Royal Free; A. N. Duggal, Lahore; M. P. Ellis, Univ. Coll.; E. H. Evans, Univ. Coll.; R. E. M. Fawcett, St. Bart.'s; C. L. Ferguson, London; Catherine F. Forrest, Royal Free; R. H. Franklin, St. Thomas's; A. M. Fratel, Bombay and Durham; J. D. J. Freeman and A. J. Gibbs, St. Thomas's; R. T. S. Goodchild, London; D. R. Goodfellow, Manchester; C. G. Gordon-Wilson, and R. K. Goyal, London; A. H. Grace, St. Bart.'s; P. R. Graves, St. Thomas's; Charlotte Gray, Univ. Coll.; Verna Hackett, Westminster, R. H. Hadley, Melbourne; B. Halfpenny, Middlesex; C. J. K. Hamilton, Liverpool; C. C. Harvey, Univ. Coll.; E. Harvey, Middlesex; Rowena M. Hickman, Bristol; Cicely L. Hingston, St. Mary's; F. K. S. Hirschfeld, Melbourne and London;

B. Horwitz, Cape and London; E. N. Jenkinson, St. Bart.'s; G. L. Johnson, Columbia Univ.; E. K. Jones, London; H. J. Knight, St. Mary's; L. J. Lannaman, St. Bart.'s; P. Lansel, Middlesex; J. B. Lloyd, London; S. McDonald, Durham; J. S. MacVine, St. Bart.'s; Margery L. Maltby, Royal Free; I. W. H. Mansfield, Middlesex; F. N. Marshall, Manchester; F. C. Mayo, King's Coll.; B. R. Medlycott, Guy's; C. W. Morley, St. Mary's; I. B. Morris, Guy's; P. D. Mottet, Univ. Coll.; F. Murray, London; J. E. Newton, Bristol; T. R. Pahwa, Glasgow; C. H. Paull, Bristol; D. D. Payne, St. Thomas's; W. Phillips, Univ. Coll.; J. O. Poynton, Charing Cross; L. D. Pringle and D. S. Raju, Guy's; H. Ramsay and G. E. Ranawake, Middlesex; P. V. Reading, Guy's; J. M. Reese, St. Mary's; J. I. Rerrie, St. Bart.'s; Colleen Rice, Charing Cross; J. Richardson, Middlesex; J. F. Riches, St. Thomas's; A. H. T. Robb-Smith, St. Bart.'s; T. G. Robinson and L. K. Robson, Guy's; K. M. Ross, St. Bart.'s; J. G. Scadding, Middlesex; S. Schenkman and A. Scher, London; M. Schlaff, St. Bart.'s; J. M. Searle, London; H. Silverstein, St. Bart.'s; C. Skinner, Guy's; Edith M. P. Smith, Charing Cross; B. T. Squires, Guy's; J. E. S. Stephens, St. Bart.'s; A. E. Stevens, London; F. H. Stevenson, Guy's; T. S. Stone, London; G. L. Stroud, St. Mary's; R. F. Taaffe-Finn, St. Bart.'s; K. T. Tasker, London; R. S. Taylor, Middlesex; E. G. Thomas, Univ. Coll.; W. E. Thomas, Cardiff and Bristol; T. F. Tierney, St. Bart.'s; C. Wall, London; Mary J. Westall, Royal Free; A. J. Whitaker, Univ. Coll.; V. M. White, London; T. H. N. Whitehurst, St. Bart.'s; E. G. Wilkins, Middlesex; D. A. Williams, Cardiff and Univ. Coll.; R. C. Williams, St. Thomas's; Rose E. Williams, Royal Free; and T. H. Wilson, St. Thomas's.

Pathology.—E. F. Adams, Manchester; J. E. G. Baker, London; F. Bartholomew, St. Thomas's; A. Burkhardt, Univ. Coll.; F. W. Chippindale, Guy's; A. F. H. Coke, St. Mary's; P. Frankenberg, St. Bart.'s; E. J. Goldsmith, St. Thomas's; R. T. S. Goodchild, London; P. R. Graves and P. Y. Hicks, St. Thomas's; S. W. Holmes, St. Mary's; O. Ive, Guy's; E. K. Jones, London; H. J. Knight, St. Mary's; F. P. L. Lander, Middlesex; L. J. Lannaman, St. Bart.'s; P. A. T. Lowden, St. Thomas's; J. S. MacVine, St. Bart.'s; J. H. G. Mason, Middlesex; I. W. Matheson, St. Bart.'s; J. E. L. Morris, Liverpool; P. D. Mottet, Univ. Coll.; J. M. Reese, St. Mary's; D. Y. Richardson, Durham; H. Silverstein, St. Bart.'s; T. S. Stone, London; Marjorie V. N. Sudds, Royal Free; W. E. Whaite, Manchester; A. J. Whitaker, Univ. Coll.; and T. H. Wilson, St. Thomas's.

THE Royal College of Physicians of London will be closed for the summer vacation from August 12th to Sept. 14th, inclusive.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—An ordinary meeting of the Council was held on August 1st, with Lord Moynihan, the President, in the chair.

Dr. Aly Ibrahim, Dean of the Faculty of Medicine, Cairo, who was elected an Honorary Fellow in November last, attended and signed the Roll of Honorary Fellows.

On the recommendation of the Museum Committee, it was decided to establish a research scholarship of £500 per annum, payable out of the general funds of the College, tenable from year to year, for a period not exceeding seven years.

Membership of the College was conferred on 141 of those whose names appeared on p. 257 of THE LANCET last week, and upon Marjorie E. Roberts, Royal Free Hospital. Diplomas were granted jointly with the Royal College of Physicians, according to the list published on the same page.

The King of Egypt paid a visit to the College on Aug. 2nd, and was made an Honorary Fellow. Lord Moynihan, the President, on presenting the Diploma, referred to the College's close connexion with the Egyptian School of Medicine. Fellows and Members of the College had been teachers in the School, and until recently the post of Dean had been held by an English Fellow. The present Dean, Dr. Aly Ibrahim, had not long ago been made an Honorary Fellow, and within recent years nine Egyptians, trained in the School at Cairo, had become Fellows by examination. He also referred to the great personal interest taken by His Majesty in the Faculty of Medicine at Cairo, and the Kasr-el-Aini Hospital. King Fuad, having signed the Roll of Honorary Fellows, inspected the Museum and other parts of the building.

A MEMORIAL NURSES' HOME.—Princess Mary last week opened a new nurses' home at the Royal West Sussex Hospital, Chichester, which has been built as a memorial to the late Dr. David Ewart, who was for many years associated with this institution as surgeon. The Princess also unveiled a memorial to Dr. Ewart.

A WELSH MATERNITY HOSPITAL.—A maternity hospital is being added to the Montgomeryshire Infirmary, at Newtown, and when the foundation-stone was laid last week by Mrs. David Davies, it was stated that this is the first institution of the kind in Mid-Wales.

EPSOM COLLEGE.—On every recent Founder's Day at Epsom College there has been a steady record of progress, showing that the intimate connexion of the school with medicine is associated with advance in the general status of the College as a public school. Proceedings this year were no exception to the rule. Prior to the prize-giving, the Council entertained 150 guests at luncheon, and over a thousand parents and friends of the College were present on Saturday, July 27th, when Lord Eustace Percy gave away the prizes. In doing so he took as the main point of his address to the boys the need for understanding one's fellow men and women—that he held to be the prime point in what he understood by the word "education." General education meant getting to know men and women, to know the minds of men and women, to sympathise with them, and in the fullest sense to understand them. The world would not fail for lack of specialists, but it might very well fail for lack of people with simple human understanding and the power of handling other fellows. That was the cement that kept society together, and in this country they never needed it more than to-day.

The Headmaster, Mr. Arnold Powell, having detailed the successes of the school during the past year in examinations, Dr. Raymond Crawfurd, Chairman of Council, in moving a vote of thanks to Lord Eustace, referred to the business side of the school's affairs. The scale of masters' salaries, he said, had been considerably increased during the present year, additions had been made to the dietary, and many improvements had been effected for the well-being of the boys, such as alterations in the swimming bath, the provision of an electrolyser for disinfection, the building of a new changing room for one of the houses, the utilisation of Lord Beaverbrook's donation for the furtherance of scientific education, and the provision of a new cricket practice pitch, the gift of Mr. Chudleigh. Referring to changes to take place in the immediate future, he mentioned the building of a new rifle-range, and considerable structural alterations at Wilson House. He hoped, finally, that the building of the new sanatorium would not long be delayed, as, with its completion, the Council would consider their main plans of enlargement to have been brought to a successful conclusion.

During the afternoon the present generation administered a sound hiding to the Old Boys on the cricket field. They declared their first innings closed on the Friday with the fine score of 370 for 3 wickets, to which the Old Boys replied with 302 all out. The College again declared with 210 for 8, and the Old Boys could only total 178 in reply. J. D. W. H. Pettigrew, in the first innings, scored 180 not out for the school, giving only one chance, and C. S. Taylor hit hard in each innings for 83 and 52 not out respectively.

On Saturday evening the College Dramatic Society gave a performance of Mr. Bernard Shaw's "St. Joan."

THE Minister of Health has appointed Mr. H. W. S. Francis to be a Principal Assistant Secretary, and Mr. R. H. H. Keenlyside and Mr. J. N. Beckett to be Assistant Secretaries of the Ministry.

METROPOLITAN ASYLUMS BOARD.—A three months' course of lectures and demonstrations on clinical practice and in hospital administration will be given at the North-Eastern Hospital, St. Ann's-road, Tottenham, N.15, by Dr. F. H. Thomson, the Medical Superintendent, on Mondays and Wednesdays at *4.45 P.M.*, and alternate Saturdays at 11 A.M., beginning on Wednesday, Oct. 2nd. Particulars may be had from the Clerk to the Board, Victoria Embankment, E.C. 4.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—A special course in Diseases of Children will be given at the Queen's Hospital for Children from August 13th to 21st. It will occupy the whole of each day with demonstrations, operations, and lectures. Courses in September will be held as follows: Diseases of the chest, Brompton Hospital, Sept. 9th to 14th; diseases of infants, Infants Hospital, Sept. 9th to 21st; psychological medicine, Bethlem Royal Hospital, Tuesday and Saturday mornings, from Sept. 10th to Oct. 5th; medicine, surgery, and the specialties, Westminster Hospital, for men graduates only, Sept. 16th to 28th. An experimental all-day course in gastro-enterology will be given at the Prince of Wales's Hospital, Tottenham, from Sept. 30th to Oct. 4th. Post-graduates interested are asked to apply early for the syllabus. The Metropolitan Hospital, Kingsland-road, will give an experimental all-day course in medicine, surgery, and the specialties, from Oct. 21st to Nov. 2nd. A course for the M.R.C.P., Lond. examination will be given at 8.30 P.M. on Tuesday and Friday evenings, from Oct. 15th to Dec. 6th, at 11, Chandos-street, Cavendish-square, W. Full particulars of all courses are obtainable from the Secretary of the Fellowship, at 1, Wimpole-street, London, W. 1.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

MONDAY, August 12th, to SATURDAY, August 17th.—QUEEN'S HOSPITAL FOR CHILDREN, Hackney-road, Bethnal-green, E. Special Course in Diseases of Children, Demonstrations, Operations and Lectures. All day Course.—ALL SAINTS' HOSPITAL, Vauxhall Bridge-road, S.W.—Special Course in Urology. Afternoons and evenings.—Further particulars from the Fellowship of Medicine.

Appointments.

JAMESON, R. C., M.D., C.M.Edin., has been appointed Certifying Surgeon under the Factory and Workshop Acts for Leeds North District.

RAWSON, W. F., F.R.C.S. Edin., Hon. Surgeon to the Waddilove Samaritan Hospital for Women, Bradford.

Vacancies.

For further information refer to the advertisement columns.

Barnsley, Beckett Hospital and Dispensary.—H.P. £140.

Birkenhead General Hospital.—Cas. S. £100.

Bolingbroke Hospital, Wandsworth Common, S.W.—H.S. At rate of £120.

Bournemouth, Royal Victoria and West Hants Hospital.—H.S. At rate of £120.

Bradford Children's Hospital.—H.S. and H.P. Each £120.

Bradford, Royal Eye and Ear Hospital.—Jun. H.S. £120.

Burnley, Victoria Hospital.—H.P. £125.

Burton-on-Trent, General Infirmary.—2nd Res. H.S. £150.

Cardiff, King Edward VII. Welsh National Memorial Assn.—Area Asst. Tuber. Physician. £600.

Cardiff City Mental Hospital, Whitchurch.—Res. Clin. Asst. 50 gns.

Carlisle, Cumberland Infirmary.—H.P. Also H.S. to special Departments. Each at rate of £155.

Cheshire Joint Sanatorium, Market Drayton, Salop.—H.P. £250.

Cheshire, Royal Hospital.—Asst. M.O. £350.

Dewsbury County Borough.—Asst. School M.O. and Asst. M.O.H. £600.

East London Hospital for Children, &c., Shadwell, E.—Res. H.S. and H.P. Each at rate of £125.

Exeter, Royal Devon and Exeter Hospital.—Asst. H.S. At rate of £100.

General Lying-in Hospital, York-road, S.E.—Res. M.O. At rate of £100.

Glasgow, Govan District Asylum.—Jun. Asst. M.O. £325.

Golden Square Throat, Nose and Ear Hospital, W.—H.S. £100.

Harrogate Infirmary.—Sen. and Jun. H.S.'s. At rate of £150 and £100 respectively.

Hull Royal Infirmary.—Second H.S. At rate of £150. Also Cas. H.S. At the rate of £130.

Ilford Emergency Hospital.—Hon. Aural S. Also Sen. H.S. £150.

Inverness, Northern Infirmary.—H.P. and Jun. H.S. £100.

Ipswich, East Suffolk and Ipswich Hospital.—H.S. At rate of £120.

Jewish Maternity Hospital, Underwood-street, E.—Res. M.O. At rate of £50.

Leicester, North Evington Infirmary.—Res. M.O. £250.

Lincoln, Bracebridge Mental Hospital.—3rd Asst. M.O. £350.

Liverpool Open Air Hospital for Children, Leasowe.—Jun. Res. M.O. At rate of £200.

Liverpool, St. Paul's Hospital, Old Hall-street.—H.S. £100.

London Female Lock Hospital, 283, Harrow-road, W.—H.S. At rate of £150.

London Temperance Hospital, Hampstead-road, N.W.—Cas. O. At rate of £120.

Lowestoft and North Suffolk Hospital.—H.S. £120.

Manchester and District Radium Institution.—Asst. Radiologist. £250.

Manchester Victoria Memorial Jewish Hospital.—Sen. H.S. £250. Also Jun. H.S. At rate of £125.

Milford, Surrey County Sanatorium.—2nd Asst. M.O. £400.

Miller General Hospital, Greenwich-road, S.E.—Cas. O. At rate of £150.

Nottingham General Hospital.—Asst. Res. Cas. O. At rate of £150.

Nottingham Children's Hospital.—Res. H.S. At rate of £150.

Portsmouth Royal Hospital.—Cas. O. At rate of £100.

Richmond Royal Hospital.—Jun. H.S. £100.

Rochester, St. Bartholomew's Hospital.—H.P. At rate of £175.

Rotherham Hospital.—H.P. £180.

Royal Air Force Medical Service.—Temporary Commissions.

Royal Eye Hospital, St. George's-circus, S.E.—12 Salaried Refractionists. 12 Clinical Assts. Also 1 Pathologist.

Royal Waterloo Hospital for Children, &c., Waterloo-road, S.E.—Clin. Assts.

St. Mary's Parish Infirmary, Highgate-hill, N.—Radiologist. £125.

Scarborough Hospital and Dispensary.—Two H.S.'s Each at rate of £126.

Sheffield, Jessop Hospital for Women.—Sen. Res. O. £250.

Swansea Hospital.—H.S. £150.

Swindon and North Wilts Victoria Hospital.—Hon. Aural Surg.

University College Hospital, Gower-street, W.C.—Asst. Radiologist. £200.

Warwickshire, King Edward VII. Memorial Sanatorium.—Sen. H.P. and Jun. H.P. At rate of £275 and £200 respectively.

Weston-super-Mare, Queen Alexandra Memorial Hospital.—Res. M.O. £130.

West Bromwich and District General Hospital.—H.S., H.P., and Cas. H.S. Each at rate of £200.

West Riding of Yorkshire.—County M.O.H. £1600.

Wigan County Borough.—Clin. Tuber. O. and Asst. M.O.H. £750.

Winchester, Royal Hampshire County Hospital.—Res. H.S. £150.

Woolwich and District War Memorial Hospital, Shooters' Hill, S.E.—Jun. H.S. At rate of £125.

The Chief Inspector of Factories announces vacant appointments for Certifying Factory Surgeons at Carnoustie (Angus) and Ringwood (Hants).

Births, Marriages, and Deaths.

BIRTHS.

BAKER.—On July 30th, the wife of Ormonde A. Baker, M.B., Langton's Meadow, Farnham Common, Bucks, of a son.

CASSELLS.—On July 28th, at The Old Oak House, Pembridge, Herefordshire, the wife of Dr. David A. K. Cassells, of twin sons.

SHAW.—On July 22nd, at Lower Baggot-street, Dublin, the wife of Captain G. W. B. Shaw, R.A.M.C., of a son.

SPENCER-PAYNE.—On July 30th, at Hempsted Lodge, Woodside Park, the wife of A. Ll. Spencer-Payne, M.R.C.S., L.R.C.P., L.D.S., of a daughter.

MARRIAGES.

SALEEBY—BILLINGE.—On July 30th, at St. Augustine's, Kilburn, Caleb Williams Saleeby, M.D., F.R.S.E., to Muriel Gordon, eldest daughter of the late Rev. Robert Burland Billinge, of Ulverston.

DEATHS.

GORDON.—On July 24th, at Pembroke-mansions, Dublin, Thomas Eagleson Gordon, M.Ch., President, Royal College of Surgeons in Ireland, aged 62 years.

HIGHET.—On July 20th, at a London nursing home, Hugh Campbell Highet, M.D., D.P.H., of Radley House, Winchester, late of Bangkok, Siam, aged 62 years.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

INDEX TO "THE LANCET," VOL. I., 1929.

THE Index and Title-page to Vol. I., 1929, which was completed with the issue of June 29th, is now ready. A copy will be sent gratis to subscribers on receipt of a post-card addressed to the Manager of THE LANCET, 1, Bedford-street, Strand, W.C. 2. Subscribers who have not already indicated their desire to receive Indexes regularly as published should do so now.

Notes, Comments, and Abstracts.

ARROWROOT,

ITS MEDICINAL AND DIETETIC VALUE.

BY JOHN CAMPBELL, PH.D.,
HON. SCIENTIFIC ADVISER TO THE WEST INDIA COMMITTEE.

FOR generations genuine arrowroot has been regarded by the medical profession as a valuable food in sick-room dietary. The word "arrowroot" is derived from the Indian term Ara-ruta, meaning a "mealy root," and it well describes the characters of the rhizome of the *Maranta arundinacea*, grown in the British West Indies, from which the genuine arrowroot is prepared. The plant is a native of tropical America and was formerly largely cultivated in Bermuda, but the manufacture of arrowroot has ceased in that island and is now centred in St. Vincent.

The objects aimed at in the preparation of arrowroot are the preservation of its colour and flavour, with the elimination of fibre and the bitter principles which are present more or less in all starch yielding rhizomes and roots. The fresh rhizomes are washed, pared, washed, and then graded to a fine pulp. The subsequent operations involve frequent dilutions with water and straining before passing to the settling table, where the supernatant fluid is drained off. The residue is then washed until the effluent runs clean, after which it is transferred to the drying house and air dried. The colour and flavour depend upon the efficiency of the washing, straining, and settling processes, and the different grades of arrowroot indicate the degree to which the purifying and eliminating processes are carried.

The manufacture of arrowroot as carried out under present conditions in the West Indies is not based on up-to-date methods; no modern machinery is used and the process is laborious and wasteful. Efforts are now being made by the West India Committee to introduce modern machinery, in properly constructed factories, which will reduce the cost of production, and lower the price of this valuable carbohydrate food.

The statement often met with in text-books that arrowroot is specially prone to absorb moisture and foreign flavours is not justified. In a special research inaugurated by the West India Committee it was found that arrowroot starch was neither better nor worse than other starches in that respect, and that this reputation was probably due to the careless way in which arrowroot was formerly packed for export, and marketed in this country.

The following is an analysis of St. Vincent arrowroot compared with potato, maize, and cassava starch.

Analyses (Willmott).

—	St. Vincent arrowroot.	British arrowroot.		Brazilian arrowroot (cassava starch, Manihot utilissima.)
		Potato starch.	Cornflour (maize starch).	
Moisture ..	15·15	16·20	11·91	14·16
Protein ..	0·10	0·12	0·40	0·18
Fat ..	0·02	0·03	0·10	0·03
Starch ..	84·45	83·37	87·37	85·41
Fibre ..	0·03	0·03	0·05	0·03
Ash ..	0·25	0·25	0·17	0·19
—	100·00	100·00	100·00	100·00

The energy value of St. Vincent arrowroot is 112 calories per ounce. The analysis shows it to be a very pure amyloid food, characterised by an extremely low protein and fibre content; this confirms the statement of most authorities that it leaves practically no residue in the digestive tract. The ash contains calcium, potassium, and iron as phosphates, chlorides, and silicates. The phosphorous content of the ash amounts to 21·2 per cent.

In most text-books the vitamin content of arrowroot is given as nil, but recent experiments made at the Lister Institute appear to show that root starch—i.e., arrowroot—contains a hitherto unnoticed constituent not present in cereal starch. When the protein of the rat diet is dried before being added to the daily ration, certain deficiencies in the nutrition are evident. If, however, arrowroot starch is added to the diet as a carbohydrate constituent, this deficiency is rectified, but not by wheat, rice, or maize starch. The nature of this constituent has not been determined, but if not an actual vitamin, it has an allied action.[1]

The most important property of starch is the quality of forming with water a jelly at a temperature which varies for the different varieties of starch. The starch molecule is generally considered to consist of amylose, found principally in the internal part of the grain, and amylopectin found mainly externally. The amylopectin confers the property of gelatinisation. The amylose is the "granulose" and the amylopectin the "farinose" of the older nomenclature. From the dietetic standpoint the gelatinising properties are the more important, as they concern the breaking up and bursting of the granules and the setting free of the nutrient constituents for digestion. The more thorough the gelatinisation the more rapid and thorough the assimilation and the less the residue of undigested matter. As an average of many tests Willmott obtained the following gelatinisation point of the named starches:

St. Vincent arrowroot..	73° C.	Maize	70° C.
Cassava	66° C.	Potato	65° C.

The high gelatinisation point of St. Vincent arrowroot ensures a thorough breaking down of the starch granules and confirms the observation that arrowroot is the most digestible form of starch.

This conclusion is confirmed by the researches of A. Dobroslavine who found that arrowroot required less saliva to produce a given quantity of sugar than all other starches, and that equal quantities of saliva acting on arrowroot and other starches produced more sugar in the arrowroot digestion in a shorter time than in cereal starches.[2]

In the earliest references the term "arrowroot" was reserved for the starchy products of the various species of the *Maranta*, especially *arundinacea*. Among the substitutes for genuine arrowroot are the following: "British arrowroot" is merely potato starch. "Cornflour" is prepared from maize, and is sometimes sold as "British arrowroot." "Brazilian arrowroot" is the starch prepared from manioc (*Cassava-Manihot utilissima*). Tapioca is prepared from this starch by the addition of water, and drying by heat. Formerly the *Maranta arundinacea* was a source of "Australian arrowroot," but of late years the species Canna has replaced it, the chief being *Canna edulis*, commonly known as tous-les-mois. "East Indian arrowroot" is prepared from various species of *Curcuma*, such as *angustifolia*, *leucorrhiza* and *rubescens*. It is one of the most common adulterants of genuine arrowroot. Another form also termed "East Indian arrowroot" is manufactured in Southern and Eastern Asia, Madras, and the Malabar Coast from Travancore starch. It is known locally as tik-tikur. "Portland arrowroot" is prepared from the lily *Arum maculatum* and the tubers of the *Arum macrorhizum*, yielding 20 per cent. of starch, cultivated in the island of Portland and other South Sea islands, and in India. It is used often as an adulterant of genuine arrowroot. "Tahiti arrowroot" is prepared from the species *Tacca oceanica* or *T. pinnatifida*. Locally it is known as "pia." Its starch yield averages 38–30 per cent. "Guiana arrowroot" is the starch prepared from the yam (*Dioscorea alata*). In Brazil it is known as farinha-de-cara. It gives a 20 per cent. yield of starch. "Florida arrowroot" or Zanna starch is derived from the tuberous stems of the *Zanna floridana*.

These substitutes, especially the preparations from maize and potato, do not possess the dietetic properties of genuine arrowroot. It is therefore desirable that in all cases "St. Vincent arrowroot" should be specified.

Arrowroot is a valuable food in diarrhœa, those cases where vegetable fibre is contra-indicated, and where a diet is required leaving no residue in the alimentary tract. When used in small quantities in conjunction with milk and heated to the gelatinising point of the starch, it breaks up the coarse curd rendering the milk more digestible. With agar-agar it forms an excellent base for the administration of the mineral salts used in the radiography of gastro-intestinal disease.

THE READESK.

WE have received from Mr. W. Ross Key, of 97, Douglas-street, Glasgow, a sample Readesk, which is an apparatus for holding a book securely and at a proper distance from the eyes when reclining in a chair at any angle or resting on a bed. It consists of an expanding frame (on the principle of the "lazy tongs") for holding the book, with pins to hold down the pages, the frame being kept in a comfortable angle before the face by a cord passing round the neck of the reader. Some little pains have to be spent at first in adjusting the apparatus, but when once in position it is quite satisfactory in use, and should prove a boon not only to invalids, but to readers who like to have a hand free when smoking.

TREATMENT OF ITCHING DERMATOSES.

ACCORDING to M. Friedlander,[1] Lebedjew was the first to try intravenous injections of a 10 per cent. sodium bromide solution in pruriginous affections, and his results led to a scientific enquiry in Vienna, where the advantages of the method were confirmed. Ekzebrol, which is a 10 per cent. solution of strontium bromide in 20 per cent. glucose solution, was the direct outcome of these investigations, and is prepared for the market by the firm of Tosse (Hamburg.) The drug is administered exclusively by the intravenous route, and during the injection gives rise to a feeling of warmth, which spreads rapidly over the whole body, and of which the patient must be warned. Friedlander has never noted any ill-effects, and in one or two cases without prominent veins he has even ventured to inject the drug deeply into the glutei. This route, however, is painful, and the patients did not submit to more than two injections. The usual procedure is to administer a 10 c.cm. ampoule three times a week.

The results are described as variable. Sometimes the pruritus was controlled after three injections, in other cases as many as 16 had to be given before the symptom disappeared. Ekzebrol, it is stated, can be used both in primary general pruritus of unknown or obscure ætiology, and in that which follows or is associated with psoriasis, lichen ruber planus and eczema. Failures of course occur with this, as with all other methods, if the cause cannot be ascertained and removed.

PUBLIC HEALTH IN KENYA.

A REPORT on the Colony and Protectorate of Kenya, recently issued, states that the land area is 221,800 square miles in extent, and the water area, which includes the larger portion of Lake Rudolf and the eastern waters of the Victoria Nyanza, 4011 square miles. Mount Kenya, after which the colony is named, is 17,040 feet in height, and is capped by perpetual snow and ice. There are no marked seasonal changes such as winter and summer. At high altitudes the diurnal variation of temperature is high, being as much as 30°F. in some places, but the mean temperature varies little from month to month. The range of temperature between different parts of Kenya is very wide. At Lamu, on the coast, the mean shade temperature is 80° F. At Mombasa it is 77°F. In Kisamu, on the Victoria Nyanza it is 72·5°F. In the Rift Valley and highland areas the mean temperature is normally between 58°F. and 65°F. The rainfall is generally well distributed. Precipitation varies considerably with the physical configuration of the colony. According to a census taken in 1926, the number of Europeans in the colony was 12,529, of Asiatics (excluding Arabs), 30,583, and of Arabs 10,577, whilst the estimated African population in 1927 was 2,847,632.

In the section of the report devoted to public health it is stated that after the visit to the colony of Dr. J. B. Orr, of the Rowett Research Institute, in 1926, in connexion with the proposed pasture investigation, the subcommittee of the Civil Research Committee decided to extend the scope of the investigation to problems of human as well as animal nutrition. With funds provided by the Empire Marketing Board, two special research officers have been employed in the country, not as independent investigators, but working in closest collaboration with the local people. During 1927 two new centres, namely Kitui and Teita, were opened in the Native Reserves. A medical officer of health has been appointed to Nakuru, on account of the considerable development which is taking place in the township, and also because of the urgent necessity of instituting sanitary measures at this centre of the grain trade. Besides his duties at Nakuru, the medical officer has been responsible for both Eldoret and Kitale. The first appointment of a medical officer of health to a Native Reserve took place in the latter half of the year, and has proved a complete success. Local native councils have taken an increasing interest in health matters, and large sums of money are being voted by the councils for medical and other objects. On the coast useful measures are being taken against hookworm infestation. The willing coöperation of the people holds out great promise of definite results. Throughout the Reserves generally work is being organised, so that information about diseases, and instruction in simple hygiene, is given, as well as treatment, while at the same time information about the pathological condition of the population is being collected. The country has been free from epidemics of serious disease. Plague requires watching, but no outbreaks of any magnitude occurred during 1927. Small-pox was introduced into Nairobi from India, and uneasiness was caused from the fact that cases came under notice from a considerable area, extending as far out as the Fort Hall Reserve. Original cases had remained concealed. Probably owing to the wholesale vaccination campaign conducted two years ago, the outbreak did not assume any magnitude. The epidemic of malaria experienced in 1926 did not recur, possibly owing to the fact that the rains generally were on the short side. The problem is to be tackled energetically in Nairobi; the Government made available a sum of £20,000, to be expended during 1928, the municipality and railway authorities sharing in the expense. The International Sleeping Sickness Commission, part of whose labours were conducted in Kenya, has completed its work. It was possible during 1927 to conduct a comprehensive population survey of the lake shore. Over 200,000 individuals were examined, and only 380 cases of trypanosomiasis were detected, these mostly being found in three well-defined areas. In one small location, consisting of a population of 800 odd, over 100 cases were found. Measures to deal with the most thickly infested areas are being undertaken. The small area referred to as being especially heavily infected is to be evacuated. Other steps will include clearing of the lake shore and the construction of watering-places. All cases which were found were adequately treated, in order to render them non-infective.

Progress of the scheme for the provision out of loan funds of hospitals in various parts of the country has not been as rapid as was hoped, but a small hospital at Kiltui is practically completed, while work has been commenced on a hospital and other medical buildings at Kakamega Station.

AN INGENIOUS TRUSS.

THE "Colquhoun" truss for hernia consists of a steel spring, to which is fitted a pneumatic appliance consisting of a back pad situated at the centre of the spring, with air connexions communicating with the front pad or pads, which cover the site of the hernia. The pads are inflated by the wearer to the extent he finds most comfortable; the valve is then closed, and the pressure in the appliance remains even. The back pad serves a double purpose: (1) it substitutes a soft air cushion for the hard spring, and (2) transfers the pressure to the front pads in conformity with the movements of the wearer. The pads are constructed to include some of the well-known product "Sorbo." While rendering them practically immune from puncture, this does not interfere with the automatic movement of the air, and makes it possible to use a much softer pad than can be employed with nearly all steel spring trusses. The softness of these pads allows them to conform readily to the contour of the body, while the action of the spring, combined with the automatic pressure exercised, gives a soft yet firm holding. This pressure, which owing to the construction of the spring occurs only directly under the pads, has a natural lifting tendency on the front pad or pads, instead of a direct inward action. Any cough or sudden movement is resisted first by the air cushion and then by the spring of the truss. Owing to the special construction, it is claimed that perineal straps are unnecessary

The principle on which this appliance is designed is distinctly ingenious, and the truss should prove comfortable to wear. It is manufactured by the Uterpress Co., 65, Atlantic-road, Brixton, London, S.W., and a patent has been applied for.

NEW WOMEN'S WARDS AT GRAVESEND.—The Marchioness of Carisbrooke last week opened new women's wards at the Gravesend and North Kent Hospital.

PRESTON ROYAL INFIRMARY.—The sum of £10,000 has been allocated to the building fund of Preston Royal Infirmary by the trustees of the estate of the late Alderman T. Parkinson, who was thrice mayor of Preston.

NORTHAMPTON GENERAL HOSPITAL.—Mrs. J. G. Sears, of Collingtree Grange, Northamptonshire, has given £5000 to the Northampton General Hospital, £3000 of which is to be allocated to the purchase of radium.

A NEW ORTHOPÆDIC HOSPITAL.—A new hospital for cripples was opened on August 3rd at Harlow Wood, near Mansfield, on a site given by the Duke of Portland. There are two wards of 40 beds each, and the total cost of building and equipment was £35,000.

NEW HOSPITAL AT BOGNOR.—It is proposed to erect at Bognor a county hospital to commemorate the King's convalescence in the neighbouring hamlet of Aldwick. A site, together with a promise of £5250, has been given by an anonymous donor, and a committee has been appointed to further the scheme.

Hunterian Lecture

ON THE

TREATMENT OF VARICOSE VEINS AND VARICOSE ULCERS BY INJECTION.

Delivered before the Royal College of Surgeons of England on Feb. 8th, 1929,

By REGINALD T. PAYNE, M.B. Lond.,

FELLOW OF THE COLLEGE; CHIEF ASSISTANT TO A SURGICAL UNIT AT ST. BARTHOLOMEW'S HOSPITAL.

In introducing the subject of the injection treatment of varicose veins and varicose ulcers, the opening words of Mr. Warrington Haward, in his Hunterian Lectures on "Phlebitis and Thrombosis," given in 1906, are apposite. "It has always seemed to me that our interest in a disease should be in proportion not to the rarity, but to the commonness of its occurrence." Varicose diseases are common among all classes of the community; they cause untold discomfort and suffering amongst their victims, and in an insidious manner they are responsible for considerable economic loss. Moreover, modern feminine fashion tends to make them a social stigma. It will, I think, be conceded that the operative treatment of varicose veins is far from ideal; in the majority of cases the method is only palliative, and there is a large group for whom surgery has had hitherto little or nothing to offer on account either of the severity of the disease or the presence of complications. For these patients the crêpe bandage and the elastic stocking have been ever-present reminders of surgical failure. During recent years operative measures have been increasingly replaced by injection treatment, and while opponents of the latter are inclined to regard it as a return to the dark ages of surgery, its protagonists have tended to consider it a panacea for all forms of varicose disorder. In its modern conception injection treatment consists essentially in the intravenous injection of substances which act by damaging the endothelium of the vein and so lead to a localised thrombosis. This thrombus is then organised, and the vein left as a thin fibrous cord in the subcutaneous tissues. The process as a whole is frequently referred to as thrombo-sclerosis.

Historical Review.

The idea of introducing chemical substances into blood-vessels with the object of producing localised thrombosis is far from new. The method was first employed in 1851 by Pravaz, the inventor of the hypodermic syringe, in an attempt to cure aneurysms by the injection of ferric chloride solution. In the same year Desgranges and Valette and others of the Lyons school carried out this treatment, with a certain measure of success, in cases of varicose veins. Two years later, in 1853, both Chassaignac and Follin were using the method in Paris and showed cases at the Société de Chirurgie, but the former reported fatalities from septic complications. Broca was still using ferric chloride in 1860, and it was not till 1884 that this substance was finally abandoned as the result of further fatalities recorded by Weinlechner. The accidents arose from two causes: firstly, ferric chloride is a coagulant of blood, and secondly, sepsis was only too frequently introduced at the time of the injection. Pulmonary emboli, septic thrombo-phlebitis, septicæmia, and extensive local sloughing were the inevitable sequelæ.

In 1854 Soquet, professor of pharmacy at Lyons, introduced iodo-tannic solution, and this was employed successfully by Desgranges and Barrier, who in the same year reported 16 cures without accident. The thrombi produced by this method were firm, but the severe pain they caused necessitated rest in bed for some time. Other substances tried at this time include chloral hydrate and persulphate of iron. After 1876 perivenous injections became popular for varicose veins, hæmorrhoids, rectal prolapse, and varicocele, as there was considered to be less danger from septic complications than with intravenous methods. Englisch, Marc See, and Broca used alcohol injections in the treatment of varicose veins. As late as 1894 Deloro was defending the iodo-tannic method, but at this period all intravenous methods were in disfavour owing to the increasing use of operative measures.

At the beginning of the present century Tavel, of Berne, obtained good results with the use of intravenous 5 per cent. phenol, but combined this with proximal ligature of the saphenous vein. Schiassi, of Bologna, in 1908, used an aqueous solution of iodine and potassium iodide injected distally, but also resected a small portion of the vein locally to prevent emboli. Borchards in 1910 discovered that intravenous salvarsan cured varicose veins and was equally successful with other arsenical preparations. In 1918 Hanschell, as a result of experience of the thrombosing action of quinine when given intravenously for malaria, employed this drug in the treatment of varicose veins with some success. At this time, however, intravenous methods on the whole were certainly not popular, they were used rather tentatively, and the general opinion was that the successes were obtained more by good fortune than by wisdom.

Current Methods.

To Prof. Linser, of Tübingen, belongs the credit of trying intravenous methods in a large number of cases. Starting in 1911, this worker has successfully used 1–2 per cent. solutions of mercury perchloride in over six thousand cases. The disadvantages of this drug are those common to all mercurial preparations, and in more recent years sodium chloride has been substituted. In 1916–17 Prof. Sicard, of Paris, observed that veins were frequently obliterated as the result of injections of intravenous luargol, and soon recognised that this was due to the free soda in the solution. In 1918 he found that neutral sodium carbonate led to thrombosis and sclerosis of veins. On account, however, of the extensive sloughing which it produced in the subcutaneous tissues, it was soon abandoned in favour of the much less toxic sodium salicylate. With this drug Prof. Sicard and his co-workers have had marked success in a large series of cases. Nobl of Vienna has confirmed Linser's results with mercury perchloride, and Genevrier in France has popularised the quinine and urethane method. Many other drugs have been tried including sodium citrate, mercury biniodide, the double hydrochlorate of quinine and urea, and glucose.

In this country experience of injection therapy is confined to four or five years, but the accumulating results support the earlier work of the continental observers. The solutions most favoured are the sodium salicylate and the quinine and urethane preparations.

The Circulation in Varicose Veins.

The question of the circulation in varicose veins is a perplexing one and I do not think it is necessary to enter into it fully, but certain aspects of recent experimental work are fundamental. The essential feature of this work is that in patients with established varices of the internal saphenous vein the blood flow in this vein is, under certain conditions at least, peripheral and directed away from the heart. Magnus, using the Volkmann hæmodrometer, has shown that, in patients with a positive Trendelenburg sign, the blood flow is distally directed in the internal saphenous vein when the limb is in the vertical position, but if the limb be raised to 45° or more the flow is either stationary or is directed towards the heart in a rather slow stream. Jentzer has confirmed the work by radiographic methods. He found that an intravenous injection of strontium bromide into a varicose internal saphenous vein travelled distally. This work receives further support from Magnus's experiments with the skin microscope.

He has shown that in varicose conditions, with the limb at varying angles, the capillary blood flow in the skin of the lower leg is markedly increased immediately the hæmodrometer records a distal flow.

Admitting for the moment the validity of these experiments, the condition of the circulation in the varicose limb is as follows. Blood from the deeper parts of the limb passes upwards in the femoral vein, and on reaching the saphenous opening some of this pours into the valveless saphenous vein and travels distally. Theoretically, this blood may again reach the deeper veins via existing collaterals, or, on the other hand, may only do so after passing through the capillary bed once more, in a reverse direction. That at least part of the blood takes the latter course is suggested by Magnus's experiments. Under certain circumstances, therefore, the blood flow in the capillaries of the lower part of the varicose area is reversed in direction, and is composed of "used" blood. Granted these abnormal mechanical conditions in the circulation, physiological changes inevitably follow in the blood itself, and as a result of these tissue nutrition is impaired. Without accepting these views in their entirety, it is possible to admit that they provide the most logical explanation available of the development and the persistence of varicose ulceration, as well as of the conditions under which healing of this ulceration may be brought about.

DISCUSSION OF CASES TREATED BY INTRAVENOUS INJECTIONS.

During the past two years 230 cases of varicose veins have come under may care, the majority in the out-patient department at St. Bartholomew's Hospital. The sex incidence was 44 males and 186 females, Injection treatment has been given in 206 cases, the age limits in this group being 16 and 76 years respectively. There has been no selection, and all cases have been treated provided definite contraindications did not exist. Fully 50 per cent. of the patients would have been regarded as quite unsuitable for surgical measures, on account either of age, general condition, the extent of the varicosities, or the presence of dermatitis or ulceration.

The quinine and urethane method has been the one of choice, and of this 1525 injections were given; 150 injections of sodium salicylate were also given, but their use was confined to patients who were intolerant of quinine or in whom there existed contraindications to its use. The quinine and urethane method was chosen from the point of view of determining its efficacy and limitations, rather than from any preconceived ideas of its superiority to other drugs.

Of the total 206 cases treatment is complete in 140, while 54 are still under treatment. Twelve patients have abandoned treatment, four on account of intercurrent disease and eight without giving any reason. Treatment in all cases has been ambulatory, no serious complication necessitating the patient's admission to hospital has arisen, and there has been no mortality. Out of the 230 cases of varicose veins treated, 24, or approximately 10 per cent., were found to be unsuitable for injections on the following grounds:—

Acute phlebitis	5	Psychoneurosis	3
Phlegmasia alba dolens ..	8	Bilateral ankle œdema ..	1*
Typhoid thrombosis ..	3	Varicules only	1
Pregnancy	1	Acute psoriasis	1
Age (74)	1		

*Unilateral varicose veins.

The reason for the rejection of these cases will be discussed more fully later, when dealing with the contraindications to injection treatment.

Detailed case-histories were taken from all patients with special attention to symptoms, the age at onset, pregnancies and the menstrual history, the occurrence of deep or superficial phlebitis, the development of dermatitis and ulceration, and a history of cardiovascular-renal disease. In all cases where any atypical symptoms or signs were present a complete general examination was made in addition to local examination.

Technique of Injections.

The quinine and urethane preparation is of the following formula:—

Quinine hydrochloride ..	4·0 g.
Urethane	2·0 g.
Aq. dest.	ad 30 c.cm.

The active principle causing damage to the endothelial lining of the vein is the quinine, the urethane merely raising its solubility in aqueous solution. On standing, the solution slowly deposits crystals of quinine hydrochloride; these can easily be redissolved by warming to body temperature. The sodium salicylate solution is made up in strengths of 20 per cent., 30 per cent., and 40 per cent.

The actual technique is similar for the two solutions. The patient stands in a good light and an Esmarch tourniquet or Martin's bandage is applied proximal to the proposed site of injection. The object of this is to render the veins prominent during the insertion of the needle, and in all cases it should be removed before the injection is made. The patient then lies down and the region of the proposed injection is carefully cleaned with ether. A 5 c.cm. record syringe carrying a No. 17 needle is filled with the required amount of solution and introduced obliquely through healthy skin into the lumen of the vein. The plunger is then slightly withdrawn to confirm the fact that the needle is in the lumen. At this point the tourniquet is removed, allowing the vein to collapse and ensuring that the quinine and urethane solution reaches the vein walls in a high concentration. As a rule, 1 c.cm. in 15 seconds is about the average rate of injection, but no force must be used and the time must depend to some extent on the resistance encountered. Pressure is then applied with an ether swab over the site of injection and the needle is withdrawn, the swab being kept in position for two minutes. The puncture is dressed with collodion on a pledglet of wool, and when dry the whole is covered with a small square of wool and firmly bandaged. The maintenance of digital pressure after injection, the collodion dressing, and the bandaging are designed to lessen the risk of leakage of blood mixed with injection material into the subcutaneous tissues around the site of puncture. Leakage is almost certain to cause local complications. The patient goes home, and returns at the end of a week for further treatment. All the patient's usual activities are permitted, rest is not enjoined, but the normal reactions which follow injection are explained.

Considerable discussion has centred round the question of the position during the injection, many workers preferring to have the patient standing. This was done in some of the earlier cases but abandoned because many of the patients objected. On theoretical grounds, it might seem desirable to insist on rest for 10–15 minutes after the injection to prevent any possible aspiration of blood into the deeper veins, but this has not been carried out and no untoward effect has been noted.

Dosage.

It is advisable to commence with a small dose of quinine urethane solution and for the first injection 0·5 c.cm. is invariably employed. This has a twofold object, the first being to test the local reaction of the veins to the solution, and the second to discover whether or not the patient possesses any special idiosyncrasy towards quinine. Subsequent injections are, in practically all cases, 2 c.cm. per dose, which can generally be relied on to thrombose 5–6 inches of a vein. Larger doses may be necessary in a few cases, but more than 4 c.cm. should never be given at one sitting. It is important to follow cases closely to see exactly what degree of thrombosis injections are producing, for individual differences play a large part and injections must be regulated accordingly.

The technical details for sodium salicylate solutions are the same as for quinine, except in dosage. Injections should begin with 2 c.cm. of 20 per cent. solutions, which will usually thrombose about 4 inches of vein. Later injections must be regulated according to the amount of thrombosis produced. If the 20 per cent. solution is adequate, injections may be confined to this; if inadequate the 30 per cent. or 40 per cent. solutions must be tried in doses up to 4 c.cm. until the requisite effect is obtained. It is important to bear in mind the fact that veins appear to establish a remarkable tolerance towards salicylate solutions, as a consequence of *which they fail to thrombose.* For this reason the surgeon should work as rapidly as possible up to a dose and strength which produces the required effect.

Whichever solution is used I do not think it is desirable to attempt to produce more than about 5 inches of thrombosis each time; if more is done the method is likely to cease to be strictly ambulatory, owing to the discomfort produced.

Site.

In general, treatment should be commenced in the most distal part of the limb, and each succeeding injection given proximal to its predecessor. This enables the operator to distinguish at once thrombosed from non-thrombosed veins. An exception to this rule is made when the varicose condition involves the region of the ankle-joint. Veins in this position should always be left till all others have been treated; they are then usually found to be entirely symptomless and very much smaller in size. If, however, it is decided to inject this region, it is as well to bear in mind that boots and shoes are likely to cause considerable discomfort during the thrombosis.

Using the doses described above, injections will be necessary at intervals of approximately 4–5 inches along the course of varicose veins, and in this way the whole saphenous tract may be treated to within about 4 inches of the saphenous opening.

In the earlier cases, while the total amounts injected were the same as those now used, the dose was given at two or three sites spread over about 5 inches of vein. This has now been given up entirely in favour of the injection of the whole dose at one site. The results have been just as satisfactory and much less discomfort is caused.

Reactions.

1. *Quinine.*—Injections should be entirely painless, apart from the prick of the needle as it penetrates the skin; pain during the injection shows that the fluid is finding its way into the subcutaneous tissues and is an indication for discontinuing the injection at once. Thrombosis begins between 12 and 24 hours after the injection and is accompanied by slight swelling, aching, and tenderness of the vein. This pain is invariably accentuated by postural changes, and is especially noticeable in the morning. As a rule the thrombosed segment becomes partially adherent to the overlying skin as a result of mild periphlebitis but, although this occasionally shows a linear bruising, redness is unusual. After about four days the vein begins to shrink, and this process continues for at least three months. Local tenderness disappears at the end of a fortnight, but bruising may take six weeks to clear up, and at times a slight permanent pigmentation is left. All these reactions are more severe where the vein is situated over bony prominences which prevent its sinking back into the subcutaneous fat. Patients show marked individual variations in the degree of reaction. The subsequent discomfort is in most cases slight and rarely limits activity. In the present series four cases lost two days' work each, and one case one day, in consequence of more than usual discomfort.

Constitutional effects due to quinine were observed in 4 per cent. of the cases and included nausea and vomiting, tinnitus, headache, and a transient intermenstrual loss. In women quinine injections must not be given during menstruation. No general quinine reactions were seen in the male cases.

Abnormal local reactions, due to leakage of blood mixed with the quinine solution into the subcutaneous tissues, are also occasionally seen. In their mildest form these consist of blood blisters, half an inch in diameter, which dry up in about three weeks. If the local process is more severe necrosis occurs, leaving a small eschar which heals in four to six weeks. These eschars were produced in eight cases in the first 500 injections, and in three cases in the last 1000 injections. The high incidence in the former group *was due to the fact that in these the punctures were* dressed with collodion only, whereas in the latter group the special precautions described were adopted. It is highly important, I think, that this type of complication should be guarded against by all possible means, for it provides an entry for sepsis with all its attendant dangers. In the present series, however, no septic complication has been seen. This necrosis sometimes occurs at sites remote from the injection, through a vein which is very thin-walled at that point. In such cases the dosage has been too high. Three cases showed rather more extensive thrombosis than was intended, in that this reached from the region of the knee to the mid-thigh, a distance of 8 inches. These all occurred in veins which possessed no obvious tributaries and in which, therefore, the effects of stagnation were likely to be marked.

2. *Salicylate.*—The use of sodium salicylate solutions has in the present series been confined to cases which showed an idiosyncrasy towards quinine or in those associated with pregnancy. Salicylate invariably gives rise to considerable cramp-like pain during the actual injection, but the subsequent discomfort is usually less than with the quinine method. No local lesions have been observed, but the two solutions seem equally likely to produce these. Varicose veins rapidly develop a tolerance to sodium salicylate, and for this reason the doses and strength of the drug has to be increased as treatment proceeds. Occasionally this results in failure to achieve thrombosis even with large doses of the 40 per cent. solution. Quinine injections have never failed.

RESULTS IN UNCOMPLICATED CASES.

I will not attempt to present the results in statistical fashion, as this is extremely difficult. Only too often varicose veins are but a part of the clinical picture, which is obscured in no small degree by other associated conditions, of which the commonest are flat feet, hallux valgus, and the various forms of arthritis. On the whole, therefore, clinical impressions appear to be more reliable. Since injection treatment gives 100 per cent. cure in cases not associated with other pathological conditions, it can, I think, be justly inferred that, in so far as the veins are concerned, similar results are obtained in cases where the picture is complicated by the presence of other diseases.

Even from a comparatively early stage of treatment patients begin to experience relief. Bandages and elastic stockings are abandoned, usually before injections are completed, although the final functional and cosmetic results are not seen until at least three months after all treatment has ceased. From the functional standpoint, patients in whom moderate activity was only possible with limbs swathed in mummy fashion can now work and play in comfort. From the cosmetic standpoint, limbs which once resembled Saxon gouty ballusters are restored to more conventional outlines. From both these standpoints, treatment appears to be equally successful in all the various types of veins. The small and early varix of the calf, the dilated and tortuous entire saphenous vein, and the advanced, diffuse, arborescent veins of the lower leg, all respond well. Injection methods are also applicable to the spidery varicules so often seen in women; these are often almost symptomless and in the present series they have only been treated when complicated by recurrent subcutaneous ruptures. Whichever type of case is considered, one of the most striking features of treatment is the remarkable recovery of tone and elasticity of the thinned and atrophic skin after obliteration of the veins.

All cases should be kept under observation for at least a year after treatment has finished.

He has shown that in varicose conditions, with the limb at varying angles, the capillary blood flow in the skin of the lower leg is markedly increased immediately the hæmodrometer records a distal flow.

Admitting for the moment the validity of these experiments, the condition of the circulation in the varicose limb is as follows. Blood from the deeper parts of the limb passes upwards in the femoral vein, and on reaching the saphenous opening some of this pours into the valveless saphenous vein and travels distally. Theoretically, this blood may again reach the deeper veins via existing collaterals, or, on the other hand, may only do so after passing through the capillary bed once more, in a reverse direction. That at least part of the blood takes the latter course is suggested by Magnus's experiments. Under certain circumstances, therefore, the blood flow in the capillaries of the lower part of the varicose area is reversed in direction, and is composed of "used" blood. Granted these abnormal mechanical conditions in the circulation, physiological changes inevitably follow in the blood itself, and as a result of these tissue nutrition is impaired. Without accepting these views in their entirety, it is possible to admit that they provide the most logical explanation available of the development and the persistence of varicose ulceration, as well as of the conditions under which healing of this ulceration may be brought about.

DISCUSSION OF CASES TREATED BY INTRAVENOUS INJECTIONS.

During the past two years 230 cases of varicose veins have come under may care, the majority in the out-patient department at St. Bartholomew's Hospital. The sex incidence was 44 males and 186 females. Injection treatment has been given in 206 cases, the age limits in this group being 16 and 76 years respectively. There has been no selection, and all cases have been treated provided definite contraindications did not exist. Fully 50 per cent. of the patients would have been regarded as quite unsuitable for surgical measures, on account either of age, general condition, the extent of the varicosities, or the presence of dermatitis or ulceration.

The quinine and urethane method has been the one of choice, and of this 1525 injections were given; 150 injections of sodium salicylate were also given, but their use was confined to patients who were intolerant of quinine or in whom there existed contraindications to its use. The quinine and urethane method was chosen from the point of view of determining its efficacy and limitations, rather than from any preconceived ideas of its superiority to other drugs.

Of the total 206 cases treatment is complete in 140, while 54 are still under treatment. Twelve patients have abandoned treatment, four on account of intercurrent disease and eight without giving any reason. Treatment in all cases has been ambulatory, no serious complication necessitating the patient's admission to hospital has arisen, and there has been no mortality. Out of the 230 cases of varicose veins treated, 24, or approximately 10 per cent., were found to be unsuitable for injections on the following grounds:—

Acute phlebitis ..	.. 5	Psychoneurosis ..	.. 3
Phlegmasia alba dolens	.. 8	Bilateral ankle œdema	.. 1*
Typhoid thrombosis	.. 3	Varicules only ..	.. 1
Pregnancy	.. 1	Acute psoriasis ..	.. 1
Age (74)	.. 1		

*Unilateral varicose veins.

The reason for the rejection of these cases will be discussed more fully later, when dealing with the contraindications to injection treatment.

Detailed case-histories were taken from all patients with special attention to symptoms, the age at onset, pregnancies and the menstrual history, the occurrence of deep or superficial phlebitis, the development of dermatitis and ulceration, and a history of cardiovascular-renal disease. In all cases where any atypical symptoms or signs were present a complete general examination was made in addition to local examination.

Technique of Injections.

The quinine and urethane preparation is of the following formula:—

Quinine hydrochloride	..	4·0 g.
Urethane	..	2·0 g.
Aq. dest.	..	ad 30 c.cm.

The active principle causing damage to the endothelial lining of the vein is the quinine, the urethane merely raising its solubility in aqueous solution. On standing, the solution slowly deposits crystals of quinine hydrochloride; these can easily be redissolved by warming to body temperature. The sodium salicylate solution is made up in strengths of 20 per cent., 30 per cent., and 40 per cent.

The actual technique is similar for the two solutions.

The patient stands in a good light and an Esmarch tourniquet or Martin's bandage is applied proximal to the proposed site of injection. The object of this is to render the veins prominent during the insertion of the needle, and in all cases it should be removed before the injection is made. The patient then lies down and the region of the proposed injection is carefully cleaned with ether. A 5 c.cm. record syringe carrying a No. 17 needle is filled with the required amount of solution and introduced obliquely through healthy skin into the lumen of the vein. The plunger is then slightly withdrawn to confirm the fact that the needle is in the lumen. *At this point the tourniquet is removed,* allowing the vein to collapse and ensuring that the quinine and urethane solution reaches the vein walls in a high concentration. As a rule, 1 c.cm. in 15 seconds is about the average rate of injection, but no force must be used and the time must depend to some extent on the resistance encountered. Pressure is then applied with an ether swab over the site of injection and the needle is withdrawn, the swab being kept in position for two minutes. The puncture is dressed with collodion on a pledglet of wool, and when dry the whole is covered with a small square of wool and firmly bandaged. The maintenance of digital pressure after injection, the collodion dressing, and the bandaging are designed to lessen the risk of leakage of blood mixed with injection material into the subcutaneous tissues around the site of puncture. Leakage is almost certain to cause local complications. The patient goes home, and returns at the end of a week for further treatment. All the patient's usual activities are permitted, rest is not enjoined, but the normal reactions which follow injection are explained.

Considerable discussion has centred round the question of the position during the injection, many workers preferring to have the patient standing. This was done in some of the earlier cases but abandoned because many of the patients objected. On theoretical grounds, it might seem desirable to insist on rest for 10–15 minutes after the injection to prevent any possible aspiration of blood into the deeper veins, but this has not been carried out and no untoward effect has been noted.

Dosage.

It is advisable to commence with a small dose of quinine urethane solution and for the first injection 0·5 c.cm. is invariably employed. This has a twofold object, the first being to test the local reaction of the veins to the solution, and the second to discover whether or not the patient possesses any special idiosyncrasy towards quinine. Subsequent injections are, in practically all cases, 2 c.cm. per dose, which can generally be relied on to thrombose 5–6 inches of a vein. Larger doses may be necessary in a few cases, but more than 4 c.cm. should never be given at one sitting. It is important to follow cases closely to see exactly what degree of thrombosis injections are producing, for individual differences play a large part and injections must be regulated accordingly.

The technical details for sodium salicylate solutions are the same as for quinine, except in dosage. Injections should begin with 2 c.cm. of 20 per cent. solutions, which will usually thrombose about 4 inches of vein. Later injections must be regulated according to the amount of thrombosis produced. If the 20 per blood is to be maintained. Any lesion of intima, be it chemical, physical, mechanical, or bacterial, will lead to a secondary thrombosis in the damaged area. All that injection does is to produce localised endothelial damage by means of drugs which act either by physical or chemical properties. The actual cure is brought about by physiological changes which occur as a result of this damage. Many observers have made histological studies of veins, both in man and in animals, at varying intervals after the introduction of sclerosing substances. Jentzer, using a solution of sodium salicylate with collargol, has demonstrated these changes, the latter drug being added to show the limits reached in the vein wall by the solution. Whereas the greatest change occurs in the intima, there are concomitant changes in the media and even in the adventitia. These experiments were carried out both in man and animals. This work has been confirmed by Benet and Verne using sodium salicylate solutions on rabbits. Wolff has carried out similar experiments on dogs, using corrosive sublimate, and Hanschell has observed the histological changes in man after quinine injections.

Summarising the results of these workers, the process may be described as follows. The earliest change occurs in the endothelium and consists in a swelling of the cells; soon these begin to proliferate towards the lumen of the vessel, become more globular in shape and resemble primitive mesenchyme cells. On this very irregular surface blood platelets are deposited; and around these there forms a very adherent thrombus composed of fibrin, red blood cells and a few white blood cells. On about the fourth day organisation of the thrombus commences by the invasion of the proliferated endothelial cells. Similarly, at a very early stage, hæmorrhages occur in the media, the muscle cells lose their rounded appearance, and there is a round-cell infiltration. At about the end of a week the distinction between thrombus and vein wall is beginning to be lost, and the process of fibrosis continues slowly, till, at the end of about three months, the vein is represented by a thin fibrous cord. The gross specimens also show that from the earliest stages the thrombus is densely adherent to the vessel wall. It is undoubtedly to these histological changes that we must turn when we seek to explain the rarity of pulmonary embolus as a sequel of injection treatment.

PULMONARY EMBOLI.

A method of treatment which relies on the formation of an intravenous thrombus, during the development of which the patient is allowed to continue his normal activities, must supply an answer to the very pertinent question as to the risk of pulmonary embolus from the migration of the clot. That answer can, I think, be given. Taking major surgical operations as a whole, pulmonary embolus is responsible for one death in approximately every thousand cases. Most writers are agreed that this risk is considerably increased in operations on varicose veins, but very few large series have been published to demonstrate this. In two groups of cases quoted by Goerlich and Jeannel respectively, of 1501 operations on varicose veins, five deaths from pulmonary embolus were recorded, giving an incidence of about 1 in 300. In discussing the risks of injection treatment these figures should be borne in mind. In a recent paper McPheeters and Rice have analysed the fatalities following injection treatment. A total of 53,000 treated cases has been recorded in the literature, with only ten fatalities Of these, seven were directly attributed to the injection. The causes of death were: three from non-infected pulmonary embolus, one from pulmonary embolus associated with thrombophlebitis, and one each from septicæmia, mercury poisoning, and thrombophlebitis. There were three other deaths from pulmonary embolus, but these occurred in patients who had some other condition which might equally well have accounted for the embolus. Taking the total fatalities from all causes, including sepsis, this gives an incidence of 1 in 5300 cases. Linser quotes 6000 cases, Nobl 2960 cases, and Sicard and Gaugier "many thousand cases," all without fatality.

These figures speak for themselves. They show at least that, as far as practical results go, the risk to life of injection treatment is very much less than the risks associated with operative measures. All forms of intravenous therapy have their inherent risks; and to this rule the injection treatment of varicose veins is not an exception, but in practice these risks have been shown to be slight.

CONTRA-INDICATIONS.

The contraindications may be summarised thus:—

1. *Deep thrombosis.*—In cases in which thrombosis of the deep veins of the limb has been followed by a compensatory dilatation of the superficial ones, injections should not be given, for any interference with the latter veins will certainly further impede a circulation which is already doing its best to carry on. In practice the commonest condition of this type is phlegmasia alba dolens, and a rule should be made that in patients with a definite history of this condition varicose veins should never be injected, no matter how far the limb has recovered from its previous œdematous state. In this group typhoid thrombosis will also provide a small number of cases.

2. *Acute phlebitis.*—Veins should never be injected in patients with acute phlebitis, and in practice no cases of this type have been treated until an interval of at least six months has elapsed since the attack has subsided. Acute phlebitis is in many cases probably a low-grade infection, and to stimulate further thrombus formation at this time is an invitation to septic complications. Disregard of this rule has been responsible for some of the reported cases of septic thrombophlebitis with embolus formation.

3. *Intra-abdominal tumours.*—In all cases the primary condition must be treated before considering treatment of the veins.

4. *Cardiovascular disease.*—There does not appear to be any real objection to treating these cases provided compensation is adequate. The present series includes two cases of mitral stenosis treated successfully.

5. *Skin disease.*—The presence of some active skin disease will in a few cases contraindicate injections.

6. *Pregnancy.*—As a general rule injection treatment should not be given during pregnancy. After this is over the veins usually show marked improvement and the injections should then be given. In patients in whom veins are giving rise to severe discomfort during pregnancy treatment is, however, justified. The quinine method must, of course, not be employed, but good results can be obtained with salicylate solutions.

CONCLUSIONS.

Injection treatment is a much safer procedure than operation; the method is one which is applicable to a much wider group of cases; the technique is simple, but perhaps this very simplicity is an invitation to abuses; the treatment is ambulatory, and the results good both from the functional and from the cosmetic standpoints; the method is of great prophylactic value against varicose ulceration, and even when this is present healing can be promoted in the majority of cases. It is too early to be dogmatic about recurrences but, if they should occur, injection provides a ready means of dealing with them. For these reasons I submit that injection therapy represents a distinct advance on operative methods in the treatment of varicose veins and varicose ulcers.

In conclusion I will quote the words of our President in connexion with this subject: "In surgery the search is always for simplicity. Complicated and cumbersome methods which are inherently dangerous give way by degrees to simpler and safer procedures. In surgery, as in the other arts, the easy way is often the outcome of long experience and of trial and error."

AN EXAMINATION OF THE PATHOLOGICAL EFFECTS OF STREPTOCOCCAL TOXIN AND HÆMOLYSIN ON RABBITS,

WITH SPECIAL REFERENCE TO THE ÆTIOLOGY OF PURPURA FULMINANS.

BY R. J. V. PULVERTAFT, M.B. CAMB., M.R.C.P. LOND.,
PATHOLOGIST TO THE MEDICAL AND SURGICAL UNITS, ST. THOMAS'S HOSPITAL.

DURING the past three years I have had occasion to observe in some 250 rabbits the effects of administering streptococcal toxins and hæmolysins intravenously in fatal and sublethal doses. In the following paper an account of the clinical signs and pathological changes is offered.

The extensive literature on streptococcal toxins is concerned chiefly with the effect of intradermal injection into man. Effects ascribed to its action on other tissues, either in man or in animals, are often complicated by the fact that either living organisms or hæmolysin were also present or both. Such effects as nephritis or arthritis by toxic absorption in man are at present merely hypothetical.

Observations of Previous Workers.

It is necessary to read far back into the literature to find records of pure toxic effects on animals. The most interesting paper, which unfortunately I did not find until this work was concluded, is that of Laitinen,[1] who in 1896 precipitated cultures of a streptococcus with ammonium sulphate or amyl alcohol, or both, and injected the redissolved product into rabbits. He described hæmorrhages in pleura, pericardium, kidneys, peritoneum, and diaphragm, but published *no* histological details. He produced paralysis by direct injection into nerves, and claimed to be the first to have concentrated the toxin.

Roger, in 1892,[2] precipitated the toxin with alcohol, and found gross diarrhœa, convulsions, and death within four days in rabbits. He was able to immunise rabbits, but only with heated toxin. Many other authors, at or about this period, succeeded in killing rabbits with toxin. Their methods are sometimes subject to criticism—as, for instance, where three-months' old cultures in richly albuminous fluids were used. Perhaps the fact that these early workers did not have available protective antisera has distracted attention from their work. More recently, Stoddard and Woods[3] and Duval and Hibbard[4] have studied the nephritis produced in rabbits by the toxin. Parish and Okell[5] have used unconcentrated toxin, and protected rabbits against death with antitoxin.

Duval and Hibbard produced a glomerulo-nephritis in rabbits by a special technique. They first immunised rabbits with scarlet fever strains other than that of Dochez; later they injected living streptococci of the same strains into the peritoneum. The rabbits were killed after some hours' delay, and the peritoneal exudate, devoid of organisms, killed other rabbits on intravenous injection of 5 c.cm. Apart from the nephritis, no lesions were found, and the markedly glomerular nature of the lesions is not in conformity with my findings.

These authors failed to kill rabbits with living organisms of the types used. This is not in conformity with the work of Okell and Parish, frequently confirmed by me, on the ease, amounting to certainty, with which rabbits can be so killed, using the Dochez strain. They also failed to kill them with large doses of filtrates of cultures grown for 14 days. I have frequently found doses of from 2·5 c.cm. to 5 c.cm. fatal when 72-hour cultures of "Dochez" were used. But when strains of streptococcus, media, duration of culture, and breed of rabbits all vary, comparison is difficult. Apparently the injections were not controlled by antitoxin, and the effects were not necessarily due to the toxin as ordinarily understood.

This paper is important, as the authors base on their results the theory that the toxin is an "endotoxin," due to autolysis, or lysis by the immune rabbit, of streptococci. The evidence for this is at present inadequate. I have frequently found that filtrates of cultures do not kill in doses of 2·5 c.cm., but when concentrated to one-tenth the volume solutions have killed in doses of 0·1 or 0·25 c.cm. This may be due to extraction by alcohol of some toxin from the organism, which is then precipitated by the absolute alcohol.

Gray,[6] in a valuable and well-documented paper, produced nephritis in rabbits and in rats by using large doses of scarlet fever streptococcal filtrates. He found the changes to be chiefly glomerular; one of his published photographs is almost identical with Fig. 7. He stressed the absence of interstitial change or round-cell infiltration, and also the impossibility of giving chronic lesions.

Hartley[7] has precipitated toxin with acetic acid after dialysis. According to Besson,[8] Bonome and Bombicci also used acetic acid, after treatment of cultures with sodium hydroxide; I have been unable to confirm the reference which, however, has been widely quoted on Besson's authority. Hartley used this concentrated toxin to estimate the strength of antitoxic sera. Simultaneously, I published[9] a method of concentrating the toxin by ice-cold absolute alcohol; this toxin was also used to estimate the strength of antitoxic sera.

Thus for over 30 years it has been known that lethal effects can be produced on rabbits by concentrated streptococcal toxins; and my method at least is not new. It is, moreover, well known in the concentration of other toxins.

The Present Investigation.

The experiments summarised above are in some cases open to criticism. Where large volumes, up to 30 c.cm. of fluid are injected, the possibility of non-specific results arises. Where antitoxin controls are not used there is no proof of toxic action. Where early cultures are used, or cultures in serum broth, the action of hæmolysin is *not* excluded.

In the experiments I am about to record the volume injected rarely exceeded 2 c.cm. Controls were invariably used; a standard control was 1·0 c.cm. of intravenous antitoxic serum, administered just before injection. No control ever died. Hæmolysin was always absent—a point which is elaborated below. In order to avoid elaborate protocols it may be stated that no statement is made which was not confirmed on at least four rabbits, that in most a considerably larger number was used, and that over 150 rabbits were killed by intravenous injection.

The technique used may be given in full.

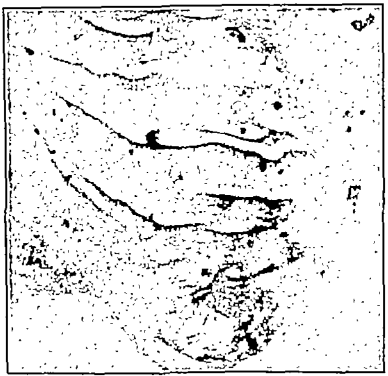
The medium used has been 2 per cent. peptone beef broth, brought to a pH of 7·6 before sterilisation (about pH 7·4 after sterilisation). The streptococcus (the scarlet fever strain "Dochez") is grown on a simple agar slope for 24 hours, and the whole slope culture, washed off with saline, is inoculated into 500 c.cm. of the medium in a litre flask. After 72 hours, 20 c.cm. are taken, cooled in a refrigerator, and then precipitated in 100 c.cm. ice-cold absolute ethyl alcohol. It is left standing for 12 hours at 0° C. Most of the precipitate adheres to the sides of the flask. The supernatant fluid is centrifugalised, and the whole deposit in 2 c.cm. of normal saline, with 0·25 per cent. phenol, is dissolved at 37° for 45 minutes, and frequently shaken. It is then filtered through a Seitz filter, and diluted 1 in 20,000, 1 in 50,000, and 1 in 100,000. 0·2 c.cm. of these dilutions is then injected intradermally into a Dick-positive person (R. J. V. P.). If a strongly positive reaction does not take place at 1 in 50,000, the culture is discarded; such preparations have been found useless on animals. If a good reaction is produced, the bulk of the culture is precipitated similarly, but redissolved in saline without phenol.

Many batches of toxin fail to yield a sufficiently high titre. While the richness of the growth is no guide to the titre of the toxin, I find that too alkaline or acid a reaction is unsuitable for toxin production. It is essential to use a human skin injection as a test of any batch of toxin, otherwise many animals may be wasted. The toxin can be dried in vacuo over sulphuric acid, and then preserves its full potency for at least six weeks.

In the course of these experiments, it was found that three successive batches of toxin prepared as above failed to give any skin reaction on the Dick-positive subject, and failed to produce any symptoms in rabbits. On plating out the culture on to blood agar, it was found that the organism was now of α-hæmolytic and *viridans* type. It has preserved these characteristics on subculture. The obvious criticisms, that the strain had got mixed, or that the strain was originally mixed, cannot be refuted. But the recent work of Grinnell[10] indicates that, when single-cell strains of scarlet fever streptococci are used, mutation from β- to α-hæmolysis is found, and that this change is associated with diminished virulence to mice. Reference to this change is also made by Todd[11] and Frobisher and Denny.[12] The change in my strain occurred when the stock organism had been allowed to grow eight days without subculture. A fresh strain from the Lister Institute was found to give good toxin, and to be of β-hæmolytic type.

Since the publication of my paper,[illegible] I have had to amplify and correct it in certain respects. In the first place, I formerly stated that 3-day cultures were the best for toxin production. Further experiments show that, while 24-hour cultures contain no rabbit-killing toxin, 72-hour and 14-day cultures contain apparently equal amounts, if the same batch of medium and the same innoculum is used throughout. Furthermore, I have found the titre of toxin, both when estimated by skin tests and by rabbit-killing effect, to vary enormously in different batches of media, grown under apparently identical conditions.

FIG. 1.



Gastric hæmorrhages; death in 48 hours following intravenous injection of 0·25 c.cm. of toxin.

I have throughout used male chinchilla rabbits, of two pounds weight. On intravenous injection I find so small a dose as 0·1 c.cm. to be occasionally fatal. A dose of 0·5 c.cm. is, however, the most probable minimal lethal dose, and in fact I use 1 or 2 c.cm. when the object aimed at is the death of the animal—e.g., when it is required to study the same toxin by intraperitoneal injection. This preparation contains no hæmolysin, which is not precipitated by absolute alcohol; neither the addition of fresh serum to the redissolved precipitate nor its oxidation or reduction renders it hæmolytic. The precipitate has been redissolved at 37° C. and at room temperature, but remains non-hæmolytic. It has been put up at pH ranges from 8 to 6 without showing power of hæmolysis. I underline this point, as, in using simple filtrates of streptococci, hæmolysin will be injected in many cases as well as toxin, though frequently it will not pass through a filter. And whatever may be the case with other organisms, streptococcal toxin and hæmolysin are quite different substances, with quite separate actions on the rabbit's tissues.

In studying hæmolysin, 6-hour serum broth cultures of the same organism were centrifugalised and the clear supernatant fluid was examined for hæmolysin. Hæmolysis at a dilution of 1 in 80, using 0·5 per cent. sheeps' cells, was accepted as a sufficient strength. The animals used had all been immunised by several small doses of toxin. Thus the effects of hæmolysin were studied, without the complication of toxic effects.

Clinical Effects of Streptococcal Toxin.

1. *On Intravenous Injection.*—The animal remains well for an hour after injection. It then becomes restless and stops eating. Diarrhœa sets in after the second hour and remains a marked symptom till death. Breathing becomes laboured and noisy; the eyes are closed and water profusely at times. Death occurs, as a rule, after a lapse of between 6 and 24 hours. Animals dying early often die in convulsions; those dying late have shown paralysis of limbs, intense conjunctivitis, great wasting, and continued diarrhœa. No death has occurred after a lapse of five days. No animal eats between the time of the onset of symptoms and death; if an animal begins eating it survives.

Between breeds of rabbits there is a great variability of sensibility to toxin, and in any one breed there is a definite individual variability to the toxin precipitated by absolute alcohol. If small doses of toxin are administered at 48-hour intervals it is possible to kill rabbits by a cumulative effect. If a rabbit recovers from one dose of toxin and is subsequently given another after a lapse of seven days, a very high degree of immunity has been acquired. As much as 15 c.cm. has been given to an immune rabbit without causing symptoms of any sort, though the same toxin was lethal to other rabbits at a dose of 0·5 c.cm. I have never succeeded in producing fresh symptoms in a rabbit which has been allowed to recover from one injection for seven days. Such rabbits have been used for the hæmolysin experiments described below.

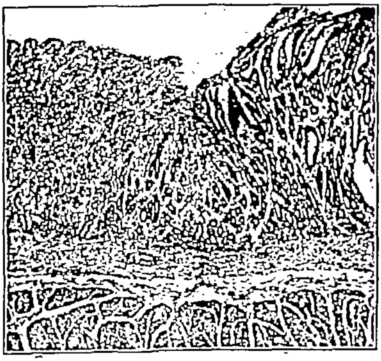
2. On *Intramuscular Injection.*—Small doses produce no effect. Ten times the dose necessary to kill by intravenous injection are required to produce symptoms by intramuscular injection. The symptoms are then similar to those found on intravenous injection, but up to the present no animals have died.

3. On *Administration by Stomach-tube.*—Of six rabbits given, by this route, from 10 to 100 times the dose fatal to other rabbits by intravenous injection, five showed no signs, and one was very ill immediately after administration and died in a few hours. No post-mortem changes were noted, and death was attributed to damage in manipulation.*

4. On *Intradermal* and *subcutaneous injection* of small doses no signs follow.

5. *Intraperitoneal injection* is fatal, but requires large doses. The changes are identical with those following intravenous injection, but the peritoneum is very much more congested.

FIG. 2.



Pyloric end of stomach: epithelial necrosis; ulcer; death in 24 hours following intravenous injection of 1 c.cm. of toxin. (× 100.)

6. *Administration directly into large or small intestine* has not yet been studied; experiments on this point are now in progress.

Blood Changes.

On intravenous injection there is great leucocytosis, but as this also occurs when antitoxic serum is given as a control it cannot be called specific. Four hours after intramuscular injection a marked polymorphonuclear leucocytosis is found, which is absent in immune rabbits. A count of 4000 cells, with 80 per cent. lymphocytes, has been converted into a count of

---

* Dietrich[11] has found tetanus toxin innocuous to mice when administered by mouth, save when bile is added.

25,000, with 75 per cent. polymorphs. This is in conformity with the results obtained by Holmes[14] and Ledingham[15] with diphtheria toxin. Blood-urea has not been found to rise; in fact there is usually a slight fall.

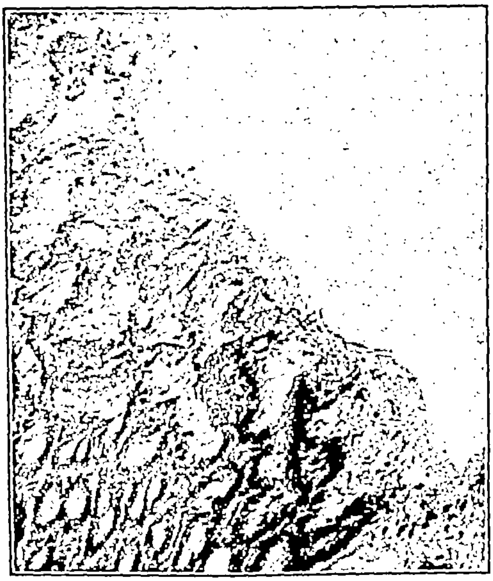
Post-mortem Changes.

1. On *intramuscular injection*, the animal being killed 24–48 hours later. No local changes, apart from needle trauma, are found in the muscles. Renal changes, slight in degree, but similar in nature to those described below, are found. No other changes were noted.

2. On *Intravenous Injection.*—In female rabbits the intense congestion of mammary vessels, first found by Hartley (loc. cit.) in his experiments on concentrated streptococcal toxin, has since been noted by me. The whole peritoneum is congested, especially that of the uteri. Subserous hæmorrhage has sometimes been noted, especially in the colon and cæcum. The bladder is usually full of urine, which does not contain blood, but does contain epithelial casts. The liver is normal; the spleen is of normal size, but is frequently very soft. The suprarenal glands are normal. The whole colon and cæcum are full of liquid fæces and of flatus. There is no macroscopic blood. The small intestine is normal, save that the Peyer's patches appear congested.

The stomach, in about 75 per cent. of the cases, shows hæmorrhagic lesions, widely distributed over the greater curvature, especially at the cardiac end. These are raised blebs, covered with epithelium, and staining the food in contact with them. Sometimes large confluent hæmorrhagic erosions are found In the pylorus depressed serpiginous lesions, which are shallow acute ulcers, are rarely found. The presence of these gastric lesions is independent of dosage, but appears to be related to the duration of symptoms; those animals dying late show them most markedly. Perforation of ulcers was never found. Animals recovering after acute symptoms, or saved by the later injection of antitoxin, never showed hæmorrhagic lesions, but did show white patches of similar distribution and contour. Administration of toxin by stomach-tube fails to produce these lesions; it must be remembered that the rabbit's stomach is never empty, even after a week's starvation, and that the gastric ferments might well destroy toxin. The administration of sodium bicarbonate by stomach-tube before intravenous injection of toxin does not prevent these lesions.

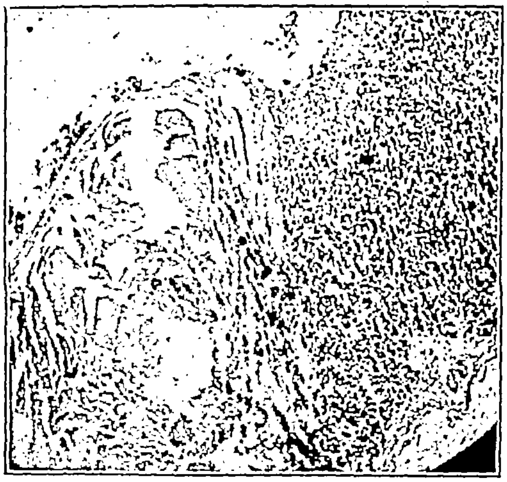
FIG. 3.



Greater curvature of stomach; rabbit killed seven days after injection of 0·5 c.cm. of toxin intravenously; severe illness; recovery. Section through white patch. (× 180.)

The kidneys are of deep plum colour, especially in the medulla and cortico-medullary junction. The right kidney is invariably more affected than the left. The lungs sometimes show hæmorrhagic consolidation of small areas at the bases; there is no general exudate. The heart on one occasion showed endothelial hæmorrhages of the musculæ papillares. The brain and spinal cord showed no lesions even in animals dying of convulsions. The joints showed no changes, either in animals dying after one dose or killed after repeated doses.

FIG. 4.



Cardiac end of stomach; section through hæmorrhagic area; death in ten hours following intravenous injection of 2 c.cm. of toxin. (× 100.)

Microscopical Examination.

1. *Kidneys.*—The glomeruli are engorged with blood, and have an exudate between Bowman's capsule and the glomerular tuft. There is marked vacuolation of the endothelium of the glomerular tuft. Elsewhere there is intense engorgement, which is most marked in the medulla between the collecting tubules. The epithelium is very greatly affected. As a rule the convoluted tubules show the greatest change; there are marked degenerative changes, the nuclei do not stain, and the cell walls are broken down. In cases where death has been caused by repeated small doses at intervals of four days there are areas of complete necrosis in the convoluted tubules. The collecting tubules show casts and a serous exudate; as a rule they preserve their staining properties very well, and the epithelial casts found in them are apparently derived from the convoluted tubules. On several occasions, however, the collecting tubules have shared in the widespread epithelial necrosis, and the epithelium is found to have desquamated. Epithelial casts are found in the urine taken after death from the bladder. I have not found any indications pointing with certainty to interstitial infiltration with leucocytes or interstitial fibrosis; but nearly all my rabbits have died within seven days of injection.

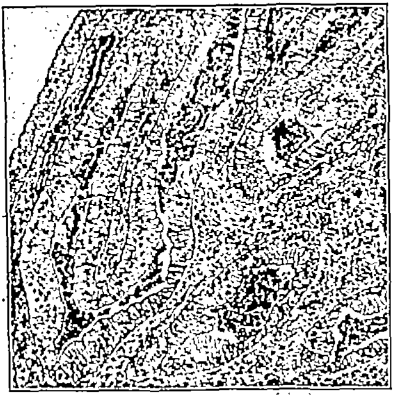
2. *Stomach.*—Lesions are confined to mucosa. There is necrosis of the epithelial cells only; the fibrous trabeculæ are unaffected. The depressed pyloric lesions and the raised cardiac lesions differ only in the presence of hæmorrhage in the latter. Such hæmorrhage is either a slight capillary leak or a large clot lifting the overlying epithelium, but confined to the mucosa. The margin of the lesions is sharply defined. Large Gram-positive bacilli were pointed out to me by Prof. Dudgeon in these lesions. The white

patches in the mucosa previously referred to in a rabbit ill for seven days are seen to be due to a superficial necrosis of the epithelium without hæmorrhage.

Experiments on Other Animals.

1. *Man.*—Reference has been made to the work of Hartley, whose advice at certain stages of my experiments I gratefully acknowledge. He finds, by his method, that the skin-test substance is concentrated to the same extent as the rabbit-killing substance, and argues that they are probably identical. O'Brien[16] confirms these statements, and suggests that the method will prove of great value in the estimation of antitoxin. On imitating Hartley's method on the toxin precipitated by alcohol I find the same results, with the proviso that the end-point both of skin-test and of rabbit-killing substance, owing to individual variation of susceptibility, is difficult to determine. In one Dick-positive person a hot bath was found to convert a negative to a positive skin-test. Very elaborate experiments would be necessary to determine identity, on which doubt has been thrown by Dochez,[17] Sacquepée,[18] Ciuca, Balteanu and Toma,[19] and Cooke,[20] among others. In solution the rabbit-killing substance appears to deteriorate with time, and on heating; this fact might be correlated advantageously with skin-test changes. Two forms of precipitate are found in the solution, when kept: (1) a crystalline deposit, which appears to be phosphatic; (2) an insoluble amorphous precipitate. Injection of both into animals is innocuous, and deterioration of toxin is not necessarily due to their appearance.

FIG. 5.



Kidney; collecting tubules. Normal epithelium; casts in lumen of tubules. Death in six hours following intravenous injection of 2 c.cm. of toxin. (× 160.)

Dudgeon and Hope-Simpson[21] found that *Staphylococcus aureus* precipitin antigens, when put up against homologous antisera, gave precipitins of two types, one of which was granular and crystalline, and the other flocculent and amorphous. It is possible that failure to obtain specific results in the precipitin experiments alluded to below was due to the spontaneous appearance in this preparation of a precipitate, which normally only occurred on admixture of specific antisera.

I find, using strains of streptococci isolated by me from human infections, that the fact that a strain will yield a skin-test filtrate does not imply that, when concentrated by alcohol, symptoms can be produced in a rabbit. But this may merely be a matter of the amount of toxin produced. Apart from the skin-test proper, experiments have been performed: (1) By dropping toxin on to the skin of the arm without breaking the surface, which has no effect. (2) By dropping the toxin into the conjunctival sac. This was three times performed, unintentionally, on a Dick-positive person. It is followed within an hour by intense conjunctivitis, blurred vision, and malaise, lasting for 48 hours. (3) Toxin on the human tongue produces a slight burning sensation.

2. *Guinea-pigs* were repeatedly given up to 100 times the dose fatal to an individual rabbit, both intravenously and intramuscularly. No clinical signs followed, and when killed no changes were found.

3. *Mice* can be killed by toxin, but they are immune, relatively to the rabbit, and require large doses, which give irregular results.

4. *Cat.*—Two cats were injected intravenously with 4 c.cm. of a toxin lethal to rabbits in a dose of 0·5 c.cm.; one was given in addition 1 c.cm. of antitoxin and remained well, showing no lesions when killed. The other, when killed after four days severe illness, showed the renal lesions illustrated in Fig. 8.

5. *Dog.*—No effect save vomiting followed the intravenous injection of 14 c.cm. of the same toxin as was used for the cat, and when killed there were no lesions.

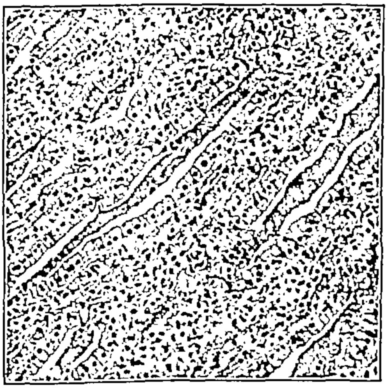
Precipitin Experiments.

Reference may be made to an attempt to estimate antitoxin by precipitin tests. The concentrated toxin gives a precipitate on dilute antitoxin, and dilute toxin on concentrated antitoxin. This is non-specific, and is also given by antisera to tetanus and diphtheria, and by normal horse serum, both when no antiseptic is added and when 0·1 per cent. formalin or 0·25 per cent. phenol is added (see Eagles[22]).

Discussion.

Too much importance should not be attributed to negative findings in this series. Since death occurs in a space of a few hours in most cases, it outpaces all save the most fulminating human infections. These experiments bear no comparison with what might occur when toxin is made and absorbed from a relatively small acute or chronic focus. In order to imitate that the method most likely to be attended with success would be to give intramuscular injections at short intervals, as by this route the toxin makes the animal ill, and keeps it ill for several days, but does not kill it. Such experiments are now being carried out.

FIG. 6.



Kidney; collecting tubules; normal epithelium; exudate in lumen. Death in 24 hours following intravenous injection of 1 c.cm. of toxin.

Therefore, although only one case showed cardiac lesions none showed evidence of arthritic or chronic renal changes, none showed evidence of iritis, and very few involvement of the central nervous system; these experiments as yet have no bearing on the question of chronic focal lesions and their metastatic result. Similarly, the experiments indicate that streptococcal toxin, if swallowed, is innocuous; they do not indicate what might happen if manufactured in other parts of the gut.

The positive results may be considered in order:—

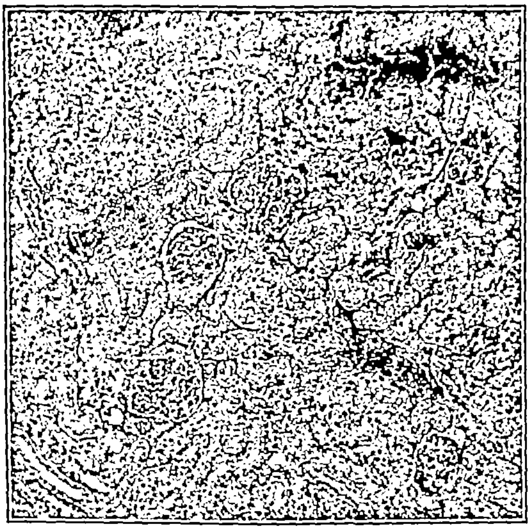
Renal Lesions.—These are not typical of scarlatinal nephritis. There is no interstitial change, even in animals surviving after severe symptoms. Glomeruli are relatively little affected. In fact, the greatest change is the intense engorgement of vessels, even to the extent of widespread hæmorrhage. While much of the parenchymatous degeneration may be secondary to this there is evidence that the proximal portions of the tubular system are specifically injured. The absence of a rise in blood-urea is probably to be neglected, in view of the early deaths. It is surprising that blood is absent from the urine.

The literature on nephritis due to experimental injection of bacterial toxins has been collected by MacNider,[23] and the specific effect on the convoluted tubules is shown to be common to many different toxins.

Gastric Lesions.—Perhaps none of the conditions in which clinical inspiration has postulated focal sepsis as causa causans has been more stressed than gastric ulcer. It is a uniform practice to remove faulty teeth in this condition. Apical cultures give conveniently positive streptococcal findings, and I have yet to meet with a sterile root, using whatever vaunted technique. But, save in acute abscesses, the streptococcus found is non-hæmolytic, and in a few cases investigated by me has failed to yield rabbit-killing toxin.

Bolton collects a long series of acute streptococcal infection associated with acute gastric ulcer. These include puerperal sepsis, scarlet fever, the suppurative stage of small-pox, and erysipelas; and many other conditions are mentioned in which, though the organism is not noted, it is probable that the streptococcus was present. But most authorities agree that such a complication is altogether exceptional. I have only met personally one possible case, where hæmatemesis with gastric erosion complicated cerebral abscess of streptococcal origin. Hæmatemesis, as opposed to frank gastric ulcer, is, however, related in another way to streptococcal infection, and this will be considered below in connexion with purpura.

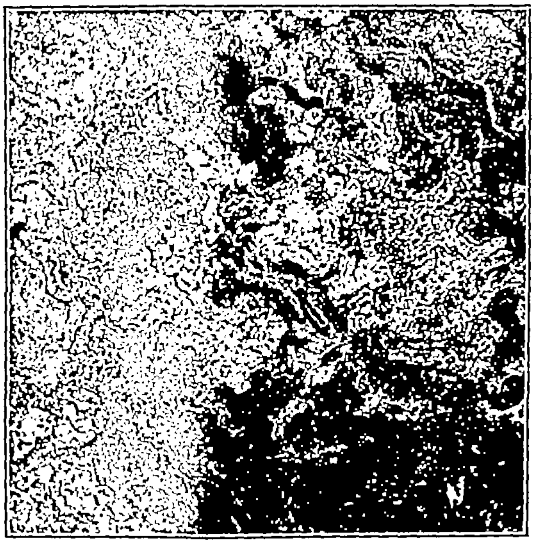
FIG. 7.



Kidney; glomeruli and convoluted tubules; exudate in capsule, and degeneration of convoluted tubules. Death in 24 hours following intravenous injection of 2 c.cm. of toxin. (× 100.)

Reference must nevertheless be made to the work of several authors on the relationship between chronic focal sepsis and chronic gastric ulcer. There is an hypothesis that streptococci localised in certain arbitrary situations may thence be transported in the blood stream, and by ingrained affinity settle down exclusively in new localities. This is particularly the view of Rosenow,[24] and the point must be stressed that gastric ulcer, on this view, is a septicæmic phenomenon, essentially involving localisation of living organisms. New evidence on this point has been produced by Haden [25] and by Nickel and Hufford.[26] These authors, by intravenous injection of living streptococci isolated from human cases of "focal sepsis," produced a high percentage of gastric hæmorrhages and ulcers. The photomicrographs appear to me to resemble the lesions produced by the toxin alone.

FIG. 8.



Kidney; cortex; complete necrosis of convoluted tubules. Death three weeks after the first of three injections of unconcentrated toxin, free from hæmolysin. (× 100.)

Thus elective localisation seems to be unnecessary as an hypothesis for the production of such lesions. It is true that streptococci were present in the lesions produced by the above authors. Prof. Dudgeon pointed out to me large Gram-positive bacilli in the ulcer shown in Fig. 2. I am unable to identify it; *B. subtilis* has been consistently grown from ulcer surfaces in these cases. However, if gastric lesions are produced by the toxin, circulating organisms might then settle there as a secondary event, whether they be streptococci or other organisms.

It is highly questionable how far the rabbit may legitimately be used as an experimental animal for gastric ulcer investigations. There are nearly fifty ways known of giving a rabbit gastric lesions of hæmorrhagic type, and Aschoff[27] states that it suffers from them spontaneously.

While, then, the direct relationship between streptococcal toxin and gastric ulcer is questionable, this series goes to show that elective localisation is not essential to ulcer formation. Finally, chronic or perforating lesions were not produced.

Purpura Fulminans.

In the ultimate analysis, a percentage of human cases of severe and fatal purpura appears to be due to endothelial trauma. An excellent discussion of these cases is given by Frank[28]; the following case, investigated by me, and under the care of Prof. MacLean, may serve as typical.

A girl, aged 8, was admitted to St. Thomas's Hospital with widespread purpura, hæmatemesis, melæna, hæmaturia and epistaxis, and high temperature. Bleeding time, coagulation time, blood count and differential count, and platelet count were normal. There was great abdominal pain and tenderness.

No diagnosis was at first offered. A small abrasion was then noticed on the right thumb; it was of a week's standing. From it a hæmolytic streptococcus was isolated; within 24 hours a culturally similar organism was isolated from a superficial abscess over the left olecranon process (? acute bursitis). Blood culture was not performed. Large volumes of scarlet fever antitoxic serum (Burroughs, Wellcome and Co.) were administered intravenously and intramuscularly, as much as 50 c.cm. per day being given. All the symptoms rapidly improved, and eventually hæmaturia alone remained. Intermittent crops of purpura were controlled by serum. The child was discharged suffering from albuminuria, which has since disappeared.

A second somewhat similar case has been brought to my notice by Prof. Dudgeon, and for the following notes I am indebted to Dr. J. W. Hope-Simpson.

A female child, aged 1 year 7 months, was admitted with history of six weeks' cough and dyspnœa. An operation was performed for empyema and a pneumococcus found. Three months later she was readmitted, and on aspirating the chest a hæmolytic streptococcus was found. Fourteen days later a very large ecchymosis about 8 in. by 2 in. appeared on the left calf, and later on similar patches developed on both elbows, both feet, both wrists, the backs of the hands, and both knees. The patches were firm, slightly raised, and plum-coloured. Further patches appeared in different places until death, which took place one month after readmission.

Post-mortem Examination.—Hæmolytic streptococci were grown from the heart blood. 0·5 c.cm. of agar slope emulsion was injected into the muscles of a rabbit, but without effect. There were numerous bright hæmorrhages on the omentum and visceral peritoneum, but no general peritonitis. The spleen was normal in size, and a film showed streptococci. There were hæmorrhages in the substance of the suprarenal glands and all around them. There were hæmorrhagic spots under the pleura. The blood in the heart had not clotted.

The above cases are admittedly rarities, but many similar ones have been reported and are referred to in the paper by Frank (loc. cit.). In all specific fevers purpuric forms are known. In the case of the meningococcus and pneumococcus an intercellular hæmolysin is found, which may be responsible for the purpura; it has been shown that the intracellular pneumococcal hæmolysin can cause non-fatal purpura in mice.

But the influence of streptococcal toxin may sometimes be the main factor. Ikeda[illegible] has shown that in purpuric small-pox direct blood-films show streptococci during life and that post mortem there are submucous hæmorrhages throughout the gut. He attributes the purpura to the streptococcus. In scarlet fever, the purpuric form is a well-known entity, known to the Germans as *Zweite Krankheit*, and Frank defines scarlatinal nephritis as renal purpura. The association of burns, on the one hand with sepsis, and on the other hand with ulceration of the intestinal tract, is perhaps suggestive in view of the gastric lesions in rabbits. The acute oral sepsis of blood diseases in their terminal stages is associated with purpura, and the bacterial infection may perhaps, in addition to the platelet deficiency, be a cause of the purpura by absorption of toxin.

The rabbit does not appear to get cutaneous hæmorrhages. I have occasionally noted blue marks in the skin, but these appear to be due to the normal pigment of the chinchilla rabbit. On the other hand, the intense mammary hæmorrhages noted by Hartley occur in organs developmentally of cutaneous origin and fall under this category. Elsewhere, all the lesions found may be explained on the basis of specific endothelial damage. The analogy between the deaths in this series of rabbits and purpura fulminans in the second week of scarlet fever appears to me complete. In the rabbits in which estimation of platelets was made there was, in fact, no diminution. But opinion is divided on the diminution of platelets in human purpura fulminans, and in the case recorded by me it was not present.

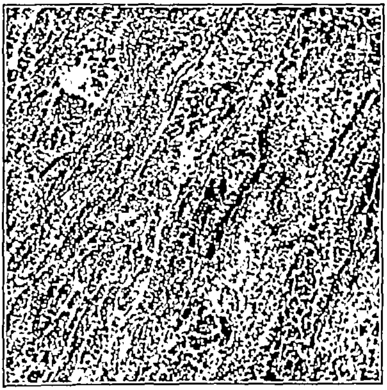
The suggestion arises from these experiments that, wherever purpura is associated, directly or indirectly, with acute streptococcal infection, it is due to the toxin of the streptococcus. In such cases, the use of antitoxic serum is indicated. It is necessary to specify antitoxic sera, since bactericidal sera are still obtainable and are devoid of antitoxic properties.

Hæmolysin.

The fact that, up to the present, analysis has failed to define "toxins" or "hæmolysins" in terms of chemical structure necessarily tends to much confusion of thought and of nomenclature.

The phenomena associated with their presence may be due to the formation by bacterial metabolism of fresh substances; they may equally be due to physical changes on the media, such as changes in the state of colloidal aggregation or of surface tension. Both words refer only to phenomena; the deduced substances have only hypothetical, though very plausible, existence. In writing of them, it is necessary either to beg the question and refer to them as substances of definite structure, or to use clumsy periphrases. I have therefore followed current use, and employed the conventional terminology.

FIG. 9.



Kidney; medulla; hæmorrhagic necrosis of collecting tubules. Death in 12 hours following intravenous injection of 2 c.cm. of toxin. (× 100.)

Kolmer[illegible] defines toxins as follows:—

> "Bacterial toxins may be defined as poisonous products produced by bacteria in both living tissues and artificial culture media. An essential property of a toxin lies in the fact that we can immunise a subject against it, and are able to demonstrate the presence of an antitoxin within the serum of an immunised animal."

If we adopt this definition—and no better one seems available—the alcohol precipitate which I have employed contains toxin.

However, early cultures of certain streptococci have the property of lysing red cells. Is this substance a toxin? And is it the same substance?

By general admission, it does not comply with the second paragraph of Kolmer's definition; antibody formation is never found. I find animals immunised against toxin to be susceptible to hæmolysin; and find antitoxic sera devoid of antihæmolysin "in vitro." Other antitoxic sera, such as diphtheria antitoxin, do contain antihæmolysin, and there are some who suppose the substances to be identical.† But this is not true of the streptococcus, as far as we know. It would be absurd to presume that the mechanism of all hæmolysis is identical in fundamental characteristics. For example, hæmolysis by sera from animals immune to the red cells of other animals requires "complement" for its completion; streptococcal hæmolysins I find unaffected by fresh serum. Streptococcal hæmolysin may be as distinct from other hæmolysins as it is from the immune hæmolysin.

---

† Mason and Glenny[illegible] titrate the toxin of *B. welchii* by estimating its hæmolytic power.

It is unnecessary here to refer in detail to the literature on streptococcal hæmolysin. It is fully collected in a paper by Cesari, Cotoni and Lavalle.[32] To their summary may be added that recent work tends to point to variability in hæmolysin production of a given strain, and to the confinement of hæmolysin production, in certain strains, to anaerobic cultures.

McLeod[33] has suggested that all toxic effects of the streptococcus may be due to the same substance, and with Channon, has recently shown that a filtrate which is hæmolytic also lyses white cells in vitro. These two authors also ascribe both the latter actions *to one substance.* But Frobisher[34] *has found* a tissue-digesting enzyme in streptococcal filtrates, and, since this is present in non-hæmolytic and hæmolytic filtrates, assumes a distinction between the two properties.

The hæmolytic power of streptococcal strains varies greatly, and "Dochez" is rather poor, rarely yielding hæmolytic filtrates capable of lysing 0·5 per cent. red cells at a dilution of over 1 in 100. Channon and McLeod used a very much more powerfully hæmolytic strain, and succeed in killing rabbits by intravenous injection of 10 c.cm. They produce hæmoglobinuria, hæmorrhagic lesions throughout the body, and focal necrosis of the liver. Other authors have used centrifugalised cultures, since hæmolysin does not always pass a filter and, if it does, loses much of its hæmolytic power.

In no case, so far as I can find, has any author used antitoxic sera in the investigation of the effects of hæmolysin. Thus experiments are apt to be confusing since, if a filtrate is used, toxin as well as hæmolysin may be present and, if centrifugalised cultures are used, living organisms are present in addition. In order to obtain high titre hæmolysin, it is essential to add serum to cultures. In the preparation of toxin, serum has never been used by me; and thus I cannot say whether in fact toxins appear, in a strength capable of killing a rabbit in serum cultures at a period when hæmolysin is high in titre.

The effect of intravenous injection of hæmolysin was tested on 20 rabbits. In doses of 10 c.cm. a filtrate hæmolytic up to a dilution of 1 in 80 on 0·5 per cent. cells produced no clinical effects; the rabbits had all been previously immunised against toxin. When killed, no changes were anywhere demonstrated. On intraperitoneal and intramuscular injection, however, local hæmorrhage was found.

The reasons why streptococcal toxin and hæmolysin are not identical may be summarised as follows:—

1. Toxin is absent, using the rabbit as test animal, in precipitated cultures up to the first 24 hours.
2. Hæmolysin is at its strongest at some period between the sixth and twenty-fourth hours.
3. Toxin is found at the seventy-second hour, and may persist till the fourteenth day at least.
4. Hæmolysin, under the conditions of these experiments, is usually absent at the seventy-second hour and always at the fourteenth day.
5. Toxin can be precipitated by alcohol and acetic acid.
6. Hæmolysin cannot be precipitated by such precipitants. The addition of fresh serum to the redissolved precipitate, oxidation by bubbling air through the fluid, or reduction by Neill and Mallory's[36] method, and the adjustment of the reaction to ranges between pH 8 and pH 6 fail to return hæmolytic properties to the solution.‡
7. Toxin, on injection into muscles, produces no local changes, but severe general symptoms and renal changes.
8. Hæmolysin, similarly injected, produces a typical tabby-cat striation of muscles, due to punctate hæmorrhages and hæmorrhage into fascial planes. It produces no *general symptoms.*
9. Toxin, injected intravenously or intramuscularly, *produces extreme leucocytosis.*
10. The injection of hæmolysin causes leucopenia, as is shown below in one series of four rabbits; actually 14 were used at different times. A 24-hour filtrate of 5 per cent. serum broth culture of Dochez (titre 1 in 80 using 0·5 per cent. red cells) was injected in 10 c.cm. doses intravenously. All animals had previously been immunised against toxin and 24 hours before the experiment 1 c.cm. of antitoxin was administered intravenously in addition.

Rabbit.	Before experiment.	4 hours after.	6 hours after.
1	10,500	5,600	8,400
2	11,300	7,700	6,900
3	7,000	4,600	6,400
4	11,900	7,900	Aborted

The leucopenia appears to be due to a diminution in the lymphocytes—e.g., in rabbit 1:—

	Before injection.	4 hours after.
Polymorphs	15	49
Small lymphocytes	82	47
Eosinophils	1	2
Mast cells	2	2

This leucopenia may perhaps be related to the leucocyte destruction shown by Channon and McLeod; it may equally be due to shock following intravascular hæmolysis. The red cells never showed any change after injection of hæmolysin.

In view of the marked differences between streptococcal hæmolysins and other hæmolysins, it was thought possible that it might be a crystalloid in spite of statements that it cannot be dialysed.

Thin collodion sacs were made and sterilised in 75 per cent. alcohol. Thence they were placed in saline. A 24-hour serum broth culture of Dochez was procured, and the titre of its hæmolysins found to be over 1 in 80 using 0·5 per cent. cells. A suspension of 0·5 per cent. human cells was then prepared in the same medium, and 2 c.cm. were placed in a sac; the sac was suspended by a thread in the culture. After 24 hours there was no hæmolysis. Therefore the hæmolysin appears not to be a crystalloid.

Discussion on Above Results.

Parish and Okell[37] have pointed out that, while rabbits can be protected against death within a few days, after injection of living organisms, by antitoxic serum, chronic infections are never prevented. That has been my own experience with rabbits immunised by toxin injections; peritonitis and arthritis were the terminal infections. In human infections with hæmolytic streptococci antitoxic serum is often dramatic in its effect. Infections with α-hæmolytic strains, on the other hand, and with certain β-hæmolytic strains not biologically distinct from the Dochez strain, were completely unaffected by the serum used.

The toxin of the streptococcus therefore seems to be only one of many weapons of the *streptococcus*, and peculiar to some strains, in my experience all β-hæmolytic. All the lesions caused by the toxin may be explained on the basis of endothelial damage, and antitoxin can only protect against that factor in streptococcal infection—a factor only rarely predominant.

---

‡ One experiment on the attempted reduction of the precipitate may be given in full. Neill[35] found that many bacterial hæmolysins became inactive, on being kept, through oxidation. This was true of *B. welchii* and of the streptococcus. Further, the intracellular hæmolysin of the pneumococcus is precipitable by absolute alcohol. It is then, however, inactive, but can be reactivated by reduction. It was therefore possible that the precipitate from my cultures contained inactive hæmolysin. A six-hour culture of the streptococcus, which was hæmolytic up to 1 in 80 against 0·5 per cent. sheep's cells, was precipitated as above described, and redissolved. A 24-hour culture of *B. welchii* was similarly treated. On testing the redissolved streptococcal preparation was non-hæmolytic; the *B. welchii* preparation showed concentration of the hæmolysin. 0·1 g. of $Na_2S_2O_4$ was placed in a tube. Immediately before use 25 c.cm. of 0·1 M. phosphate buffer solution, pH 7·4, was added. 0·2 c.cm. of this solution was taken and added to 1 c.cm. of the redissolved precipitate, and the volume made up to 2·2 c.cm. with the phosphate buffer. The mixture was immediately placed in an anaerobic jar and evacuated; it was then left for 30 minutes. No evidence whatever of hæmolysin was found. In order to control this experiment a filtrate of "Dochez" which had lost hæmolytic power on being kept, and a similar one of *B. welchii*, were treated by Neill's technique. Reactivation was found, but it was incomplete; in neither case was the final titre of the reduced hæmolysin equal to its initial highest titre. This last experiment was kindly carried out for me by Dr. L. S. Penrose. Channon and McLeod (loc. cit.) also failed to reactivate completely streptococcal hæmolysin by that technique.

Hæmolysin, as made by the Dochez strain, appears to be in itself comparatively innocuous. Even 20 c.cm. of an unusually vigorous preparation was devoid of effect in a rabbit immune against toxin on intravenous injection. It does, however, produce peritoneal hæmorrhage on intraperitoneal injection, and petechial hæmorrhage on intramuscular injection into toxin-immune rabbits.

The different results obtained by other writers may be due in part to the use of strains with greater power of hæmolysin production. As, however, in no case were antitoxin controls used, they may also be due to the injection of toxin. It is true that early cultures must be used to obtain hæmolysin, and that early cultures contain little toxin when no serum is used in the medium. The use of serum may conceivably modify toxin production, and the simultaneous injection of toxin and hæmolysin may produce effects not found with the injection of either substance separately in the doses used.

Finally, the action of toxin and hæmolysin in the tissues may well modify the further pathogenic action of the streptococcus itself.

Experiments are being performed to determine the minimum lethal dose of living organisms when injected, with and without hæmolysin, in toxin-immune rabbits.

Summary.

1. Certain strains of streptococcus produce both toxin and hæmolysin. The pathogenic activity of streptococci is not dependent solely on the toxic power, since animals immune to it may yet be killed by living organisms, although surviving longer than controls.

2. Toxin and hæmolysin are different substances, formed in culture at different times, producing different lesions in the rabbit, differing in their behaviour to globulin precipitants and in their power to evoke immune bodies.

3. Toxin, in rabbits, produces leucocytosis, hæmorrhagic nephritis, hæmorrhagic erosion and ulceration of the stomach, and hæmorrhagic lesions in mammæ, lungs, and peritoneum. It produces no changes locally on intramuscular injection.

4. The hæmolysin of "Dochez" produces leucopenia, local hæmorrhage on intramuscular injection and on intraperitoneal injection, in animals immune to toxin. Otherwise it is devoid of effect under the conditions of these experiments.

5. The human conditions best paralleled by the lesions of this toxin in rabbits are those found in purpura fulminans.

My thanks are due to the following: to Sir C. S. Wallace and Prof. H. MacLean for facilities for this work; to Prof. L. S. Dudgeon for advice and criticism; to Dr. A. L. Basham for the photomicrographs, prepared in the Unit Laboratory; to Dr. R. A. O'Brien for the strain of organism and the antisera used; and to my assistant, Mr. P. Carter, for his help and many valuable suggestions.

INTERNAL DERANGEMENTS OF THE KNEE-JOINT.*

By PAUL BERNARD ROTH, F.R.C.S. Eng.,
ORTHOPÆDIC SURGEON TO THE MILLER GENERAL HOSPITAL, GREENWICH.

"Internal derangements of the knee-joint" is an arbitrary term without logical basis. In this paper I shall confine my remarks to injuries to the menisci, injuries to the spine of the tibia, and loose bodies.

In all cases where I suspect one of these three conditions I do a complete exploratory operation, splitting the patella vertically and pulling the two halves widely apart, so as to expose the joint as fully as possible. I believe that this is the only way to be certain of dealing with the particular trouble which may be present. With one minor exception (see later) I have observed no ill-effects from this procedure, and I believe it to be harmless.

Technique of Operation.

The whole limb, having been shaved and painted with iodine, is raised in the air, and a rubber bandage tourniquet is applied to the middle third of the thigh. The limb is lowered on to a sterile towel and a sandbag is placed beneath the buttock to counteract the tendency of the limb to rotate outwards. A second sandbag is put beneath the knee.

A vertical incision through the skin and subcutaneous tissues is made in the mid-line, starting from a point 5 in. above the patella and extending to a point 3 in. below it. The edges of the wound thus made are slightly undercut, and are hidden from the area of operation by sterile towels clipped on with tissue forceps. The patella is split vertically with a chisel and mallet; with a fresh scalpel the split in the patella is continued up between the fibres of the quadriceps tendon and down between the fibres of the ligamentum patellæ, for the full extent of the wound. The two halves of the patella are drawn widely aside with special retractors and at the same instant the knee is fully flexed by a third assistant. The subpatellar pad of fat is divided in the middle line down to the tibia. The whole joint is exposed and the abnormal condition present is dealt with.

---

* Based on a paper read before the Swiss Society of Surgery at Zug on May 28th, 1929.

The two halves of the patella are then allowed to fall together and the whole gap between the split fibres of the quadriceps, the two halves of the patella, and the split fibres of the ligamentum patellæ is closed with one long continuous suture of chromic catgut. The stitches pass actually into the joint in bringing together the fibres of the quadriceps, then into the fibrous tissue covering the front of the patella, and again pass deeply to bring together the divided halves of the sub-patellar pad of fat. The skin wound is closed with interrupted horsehair. White gauze and three layers of cotton-wool are applied to the knee with a 6-in. bandage and the tourniquet removed. I employ no splint. When the patient is back in bed a small pillow is placed beneath the knee, a cradle is placed over the foot, and the end of the bed is raised on blocks. The patient is encouraged to start moving on the third day, to get up with crutches at the beginning of the third week, and to be back at work in six weeks.

In a series of 41 cases operated on at one hospital by this method there were found :—

	Cases.
(1) Mesial meniscus split or detached	17
(2) Lateral meniscus split or detached	4
(3) Loose bodies	10
(4) Spine of tibia fractured	5
(5) Joint normal, though injured meniscus suspected..	4
(6) Joint normal, though loose body suspected ..	1

(1) *Mesial Meniscus Split or Detached* (17 cases).—In every case the loose or torn piece of cartilage was cut cleanly away from the part which remained fixed in place; that is to say, the whole cartilage was not always removed, but only the abnormal portion.

(2) *Lateral Meniscus Split or Detached* (4 cases).—In none of these had a diagnosis been made of injury to the lateral meniscus.

CASE 1, a girl of 22, a restaurant worker, was seen on March 24th, 1927. Four months previously she had stooped to pick up something and felt the left knee click suddenly. This was followed by a great deal of swelling which, however, subsided in a week. Since then she had felt a click whenever she straightened the knee, which jarred her and was uncomfortable; occasionally there was pain and swelling on the outer side of the joint. On examination a definite click was felt just before full extension and a lesser click on beginning flexion. Both clicks appeared to be on the outer side of the knee-joint. A month later the patient stated that several times she had had difficulty in straightening the knee. At operation on July 5th, 1927, the anterior half of the lateral meniscus was found loose and split.

CASE 2, a boy of 10, was said to have broken his right leg four years before, and complained of his right knee letting him down frequently. He said it clicked and hurt whenever he ran and made him fall. On flexion the tibia dislocated inwards; on extension the dislocation reduced audibly.

At operation on July 26th, 1927, the lateral meniscus was found loose, displaced inwards, and enlarged to quite ten times its normal size. It was lying on the articular surface of the tibia and completely interfering with normal movement. On section the enlarged meniscus was solid right through; there was no cyst formation.

CASE 3, a man aged 34, had hurt his right knee three weeks previously when playing football. He had heard something click, felt a sudden great pain, and had to stop playing. The knee was bent and he could not straighten it; it had remained bent ever since. I tried to reduce under gas, but failed. At operation, five days later, the lateral meniscus was found split transversely and the anterior cruciate ligament partly torn through. The loose anterior portion of the meniscus was removed.

CASE 4 is still under treatment. When first seen on March 21st, 1929, he told me he had had a cartilage removed from his right knee at University College Hospital, London, 17 years before. The knee had never been quite sound since. Two months ago he was getting out of bed when his right knee became fixed suddenly in the bent position. This has since happened five or six times.

At operation on April 15th a portion of the lateral meniscus was found loose in the joint, attached by its posterior cornu only. It was enlarged to the size of an irregular pea or orange pip, and had evidently been moving in and out between the bones. The anterior cruciate ligament did not exist; shreds of it were found and were sutured together. The scar of the first operation is on the inner side. I suggest that the surgeon was dealing with a case of ruptured anterior cruciate ligament which had taken up the anterior cornu of the lateral meniscus with it, and that he removed all the lateral meniscus he could reach and the anterior cruciate as well.

(3) *Loose Bodies* (10 cases).—Two of these were remarkable.

CASE 1, a shoeing-smith aged 30, stated that two months earlier he had been shoeing the hind hoof of a horse when it suddenly pulled back while he was stooping and caused him to over-extend his right knee violently. It was frightfully painful for two or three minutes and he hardly knew how to bear it; then the pain eased off and he went on with his work. Next day the knee was twice the size of the other and very painful, but he went to work and remained at work until three weeks before examination, when, in turning round sharply, the knee gave way and became bent and remained so for two or three days. He could feel something loose under the skin on the outer side, which he could move about.

At operation a slice of articular cartilage the size of a shilling was found almost completely detached from the outer and lower aspect of the mesial condyle, and a much smaller portion was completely loose and free in the joint. The cavity in the condyle from which the pieces of cartilage had come was healed over in its whole extent with a thin bluish-white film.

CASE 2 was a man aged 58 with advanced osteo-arthritis of the right knee. The joint was tightly distended, apparently with fluid, and it was for this distension that he sought relief. On opening the knee large masses of bright yellow fat-like material welled up out of the joint. There was quite half a pint of this, and it was present in the joint under considerable pressure. The joint itself showed advanced osteo-arthritis, with erosion of cartilage and hypertrophied synovial fringes. The yellow material was completely free in the joint, and was considered by me to be a lipoma which had somehow become detached. On section and microscopical examination, however, the following report was received :—

"The masses appear to be composed of a fibrinous material. Although in a few places a vessel and a small amount of fibrous tissue can be seen, for the most part there is no organised structure; fat is not present."

(4) *Spine of Tibia Fractured* (5 cases).—Four of these cases have already formed the subject of a communication by me which has appeared in the *Journal of Bone and Joint Surgery*. They were operated upon within a fortnight of the injury. In each of them, when the patella had been split and the two halves drawn widely apart, the knee being fully flexed, the fragment of bone torn out of the top of the tibia was seen lying in the intercondylar notch, attached above and posteriorly to the anterior cruciate ligament and externally to the anterior horn of the lateral meniscus. The place from which it had been torn was represented by a deep hole in the upper surface of the tibia. Attempts to replace the fragment were entirely prevented by the lateral meniscus, which appeared to have become shrunken or contracted. It was therefore divided with a tenotome at a point a quarter of an inch away from its attachment to the fragment. With a pair of dissecting forceps the latter could then be put back exactly in place in the top of the tibia, the anterior cruciate ligament being still attached to it. With the forceps holding the fragment the knee-joint was moved from complete flexion to complete extension, in which position there was no tendency for the fragment to shift when the forceps was removed; in fact, the condyles seemed to ram it home most effectively. So no suture of any kind was used, the limb being enclosed at once in plaster. After a month the plaster was removed and massage and gentle movements started. Three of the cases recovered completely; the fourth, in which the head of the tibia was also fractured, was not able eventually to flex the knee to less than 80 degrees.

The fifth case was not seen until eight months had elapsed, and occurred in a chauffeur, as the result of a motor accident. He spent three months in bed, and the knee had been bent ever since at an angle of 120 degrees. It was impossible to straighten it because of a bony block. The lateral X ray showed a large shadow in the joint anteriorly in the angle between the femur and the tibia. At operation a mass of bone was found here, rising up from the floor of the anterior intercondylic fossa; this was chiselled off, allowing the knee to be straightened. Seen six years later, May 9th, 1929, he was completely cured, except for the last 10 degrees of extension. He had been at work ever since discharge.

(5) *Joint Normal, though Injured Meniscus Suspected* (4 cases).

In one case I used the "internal lateral" route instead of the split patella, and had a very poor view of the joint. As I could see nothing wrong I closed the wound. Now, after six and a half years, he complains that his knee still goes wrong and locks, so there is evidently some derangement which should be attended to.

In the second the menisci were healthy, but a tag of fat was lying in between the tibia and internal femoral condyle, and was removed. I doubt, however, whether this could have been the cause of the symptoms. A year later the patient reported he had been back at his work as a blacksmith for 11 months; his knee was normal.

In a third case, where there was a history of two attacks of locking and the diagnosis had been made by my assistant, nothing abnormal was found. Seen three and a half years later the knee was normal and never troubled the patient at all. He is at work as a slot-gas collector, and has to carry heavy bags full of copper coins.

The fourth case is noteworthy; it occurred in a girl of 18. Her doctor wrote: "to see Mr. Roth for ? dislocation of the semilunar cartilage. The knee is flexed and cannot now be extended." The patient informed me it was her fifth attack of locking. I tried to reduce, but failed, then had gas administered and reduced at once. As she had had so many attacks I advised operation and opened the knee five days later. To my surprise the interior of the knee was normal. Seven months later the knee became locked again, and again two months after that. I advised a knee-cage. When seen for the last time after some months the knee seemed perfectly sound. Was this a case of hysterical knee?

(6) *Joint Normal, though Loose Body Suspected.*—In this case X rays showed a shadow behind joint, but nothing was found at operation.

Remarks.

The small number of meniscus cases is explained by the fact that it is my custom to reduce displacements where possible under gas, and not to advise operation unless the displacement occurs a second time. In a very large number of cases it never does occur again. Where operation is decided on I believe, as already stated, that the surest way to avoid mistakes and obtain complete relief of symptoms is to split the patella and have a clear view of the joint. Sepsis has been entirely absent. In one case superficial sepsis occurred in the lower part of the wound, but there were three unusual factors to consider: there was some delay in the sterilisation of the instruments, it was a fresh theatre sister's first day with me, and my assistant was away ill. I ought not to have operated. Under normal conditions sepsis does not occur.

Fear of non-union between the divided halves of the patella is groundless. Clinically, at least, no damage is done to this bone and no unfavourable effect is produced. Where an X ray has been taken years later slight osteo-arthritic changes have been observed, but they do not seem to be of the slightest importance. I suggest that the *division of the patella* is much less harmful than a horizontal or oblique section of the internal lateral ligament. I believe that the operation for the removal of damaged menisci done by this method gives a 100 per cent. cure. It enables the surgeon to remove accurately and completely the whole of the loose or torn portion and, on the other hand, it ensures that he will not remove undamaged structures.

I have written to all these patients, and of the 21 meniscus cases 10 have come to see me. They are all perfectly well, at intervals of from one to six years after operation. There has never been any return of symptoms and all of them profess and appear to be perfectly recovered. At the worst one or two complain of slight aching in damp weather, or of not being able to kneel on a hard surface with comfort. Yet I have seen statistics published by other surgeons where unsoundness of the joint has persisted in from 30 to 40 per cent. of cases. Such statistics naturally bring discredit upon operative treatment and encourage recourse to unqualified bone-setters.

I can conceive of no other method which will give the perfect view required for reposition of the bone in fracture of the tibial spine and for the removal of loose bodies.

Post Scriptum.—The difficulty of operating through a small lateral incision is recognised by Prof. Fritz Steinmann, of Berne, who has devised a new instrument, the "meniscotome." This is made on the same plan as a tonsillotome. The ring of the instrument is made to encircle the free end of the detached meniscus and is pushed back along it as far as it will go; the knife then slides across the ring and cuts off the meniscus. Prof Steinmann claims that in this way none of the loose part can ever be left behind and that so little damage is done to the knee that the patient may be allowed up to walk on the day after operation.

Clinical and Laboratory Notes.

THE ASSOCIATION OF HUMAN AND CANINE JAUNDICE,

WITH AN ILLUSTRATIVE CASE.

BY C. J. MONTAGU LAWRENCE, L.M.S.S.A. LOND.,
AND
C. C. OKELL, M.C., M.B. CAMB., M.R.C.P. LOND.
(*From the Wellcome Physiological Research Laboratories, Beckenham.*)

It has always been surprising that so few cases of Weil's disease should be reported in this country, considering that as many as 20 to 30 per cent. of adult English wild rats harbour leptospiras which are almost certainly pathogenic to man. At one time it appeared possible that the epidemics of "infectious jaundice," which are by no means rare among school-children, might be ascribed to leptospiral infection, but the more fully these epidemics have been investigated the more unlikely it seems that they are due to this cause (Cockayne, 1912; Morgan and Brown, 1927; Booth and Okell, 1928). The present view, almost universally held, is that the infectious jaundice of children is a disease sui generis. In 1925 (Okell, Dalling, and Pugh) it was shown that the common malignant jaundice (or "yellows") of dogs was due to infection with *Leptospira icterohæmorrhagiæ*. When the close intimacy that exists between human beings and dogs is considered it becomes even more surprising that leptospiral disease, which is *par excellence* a contact infection, does not occur more frequently in man.

Leptospiral disease in dogs is a disease of high mortality; 90–100 per cent. of the affected puppies may die and some foxhound kennels lose as many as half of their annual puppies in this way. The disease affects practically all breeds of dogs, but is most common in kennelled dogs such as foxhounds and beagles. The signs, symptoms, and post-mortem appearances closely resemble leptospiral disease in man and other animals. Jaundice and hæmorrhagic signs are almost constantly present, petechial or even massive hæmorrhages in the lungs being particularly characteristic. In puppies intussusception, the result of hæmorrhagic enteritis, is a frequent terminal complication. For a more detailed description of the disease reference may be made to the paper already referred to (Okell, Dalling, and Pugh, 1925).

Records of the association of human and canine jaundice are very few. The first case we have been able to trace was that reported by Krumbein and Frieling in 1916, where two officers, living in the same room as a dog suffering from jaundice, developed what appeared to be typical Weil's disease. This observation

tion antedated the recognition of the leptospira as the cause of Weil's disease. Uhlenhuth and Fromme (1919), in their classical paper on leptospiral jaundice, mentioned a case of jaundice in the dog which they proved almost conclusively to be leptospiral. They were investigating an area where human cases of Weil's disease occurred, though there was no direct connexion between the canine and any human cases. When it became evident that such a common disease as "yellows" in dogs was of a leptospiral nature inquiries were made with a view to tracing cases of associated human and canine jaundice (Okell, 1925), but only two instances were discovered, one of which was reported to us by Prof. R. D. Passey, the other by Dr. R. Stirling and Mr. Lornie, M.R.C.V.S., of Perth.

The following case has recently come under our notice:—

A. B., aged 52, first whip of a pack of foxhounds, had been nursing several puppies affected with "yellows" and had performed several post-mortem examinations with naked hands during the three to four weeks previous to the onset of his illness. He had also been bitten by a fox about ten days previously, but nothing abnormal had been noted in the fox. On Dec. 11th, 1928, he had been hunting and had been suddenly seized with shivering and intense pains in the back, loins, legs, arms, and neck. He had to go to bed immediately.

On Dec. 12th, when first medically examined, he was flushed and obviously ill. Temp. 101° F., pulse-rate 140. His conjunctivæ were intensely congested and there were definite hæmorrhages beneath the conjunctival membrane. At this stage there were well-marked pulmonary signs and symptoms—patches of bronchial breathing and expectoration of blood-stained sputum. There was little cough and the respiration-rate was not appreciably increased. A provisional diagnosis of mild broncho-pneumonia was made at this stage.

On the fourth day of the illness jaundice became apparent. It quickly deepened to an intense orange yellow colour and with the onset of jaundice the temperature rapidly fell. The fæces were pale and the urine nearly black with bile-pigment. There was no tenderness over the hepatic area. The liver and spleen appeared to be of normal size. During the first week there was intermittent hiccup and on two or three occasions slight epistaxis. The pulmonary signs quickly cleared up and the jaundice deepened almost to a bronzed colour by the tenth day. At this time the posterior cervical glands were noted as enlarged and the lymphatic vessels in the region as thickened.

The diagnosis of Weil's disease was now almost certain. 10 c.cm. of antileptospiral serum of known potency was then given and five days later a further 10 c.cm. By the end of the fourth week albuminuria was detected which persisted for about eight to nine weeks; the patient made an uneventful recovery except for a slight exacerbation of temperature at the end of the third week of illness. Examination of the urine during the fourth week proved negative for leptospiras both on direct examination and by guinea-pig inoculation. The distance of the case from the laboratory made it impossible to investigate the pathology of the case in detail. From the clinical course of the disease alone, however, an almost certain diagnosis could be made of Weil's disease.

It should not be overlooked that the possibility of human beings contracting Weil's disease from affected dogs appears on theoretical grounds to be no slight one. So far as is known the pathogenic leptospiras consist of one species of micro-organism and infection from one animal's species to another is experimentally easy. The greatest risk is no doubt in the handling of internal organs—e.g., at post-mortem examination—since these usually contain the leptospira. The virus is easily transmissible by skin contact, and though we have never been able to infect guinea-pigs by placing virus on the intact skin we have been able to transmit the disease with regularity by placing a drop of virus-containing organ extract on a slightly scarified area.

Possibly the association of human with canine jaundice is not so uncommon as the recorded cases would suggest, and it is in the hope of attracting the attention of medical and veterinary practitioners, particularly in rural areas that we have thought it worth while to report this case.

ON THE MODE OF ACTION OF IRRADIATED ERGOSTEROL

UPON THE MYELIN FORMS OF LECITHIN.

BY C. J. BOND, C.M.G., F.R.C.S. ENG.,
CONSULTING SURGEON TO THE LEICESTER ROYAL INFIRMARY.

DURING an inquiry into the factors which initiate and promote the formation of myelin threads and droplets by lecithin when in contact with water, it was found that irradiated ergosterol (vitamin D) exercises a marked effect.

A solution was made in chloroform of approximately equal parts of ergosterol and pure lecithin. The lecithin used was prepared by Levene's process, and was kindly obtained for me from America by Prof. H. McLean.

The solution was divided into two portions. Portion A was exposed in a quartz tube to the rays from a mercury-vapour lamp for half an hour at a distance of 18 inches. Portion B was kept as a control. A drop from each portion was then allowed to evaporate on a slide. The film deposited from A appeared to the naked eye more translucent and homogeneous than the more opaque granular deposit from the non-irradiated B. On adding a drop of normal saline to each film and covering with a cover-slip, examination under the microscope showed a marked activation of the lecithin (by hydration or water absorption) in the radiated portion A. The lecithin begins almost immediately to form droplets and throw out myelin threads, especially in the thinner areas of the film. The rosettes of needle crystals formed by the irradiated sterol deposited from the chloroform solution also show lecithin droplets and threads round their edges.

The non-irradiated film is considerably slower in showing activity. Under dark-ground illumination the difference between the irradiated and the non-irradiated film is more easily appreciated.

It is important to examine the films at once, and at short intervals, because the active phase, during which the protrusion of myelin threads and the formation of droplets takes place, is a transitory one, and ceases sooner in the more fully hydrated and irradiated than in the non-irradiated film. Examination of the two films with polarised light shows that the myelin threads or projecting worm-like processes, which grow from the surface and edges of the deposited lecithin (as hydration proceeds) polarise well, while the isolated droplets which bud from the ends of these myelin stalks give a bright appearance with a terminal dark Maltese cross. The arms of this black cross correspond to the vibration planes of the polarising prisms (like a starch grain). The polarising capacity, which expresses the physical and not the chemical character of the material, is most marked along the edge or skin of the droplet or thread where the pellicle is thickest. As the threads grow in size the wall becomes thinner and the polarising capacity less marked. Thus, the film which contains the irradiated ergosterol undergoes hydration sooner, and passes more rapidly into the expanded thin-walled phase, than the more slowly reacting non-irradiated film.

A careful study is being made of the staining reactions of lecithin under different conditions, irradiated and not irradiated. Much has been learned, but the problem is so large and so complex that much more investigation is necessary before final or useful results can be arrived at. I have confirmed Prof. J. B. Leathes's observations[1] that the presence of cholesterol in the proportion of one part of cholesterol to four parts of lecithin does not inhibit—in our experience it actually increases—activity in lecithin when covered with water. Neither does cholesterol, in this concentration, inhibit the activating effect of vitamin D on lecithin, though it is possible that it might do so when present in larger proportions.[1]

It is necessary to inquire whether the activating effect is still present when the concentrations used more nearly resemble those present in the body during life. If we assume (see Leathes[2]) that in 100 g. of wet body-weight the amount of lecithin will be about 2 g., and if we regard the effective dose of vitamin D as 2 mg. in rickets (K. H. Coward[3]) then we have some indication of the relative proportions of ergosterol and lecithin to use outside the body in order to make these in vitro and in vivo experiments comparable.

---

[1] THE LANCET, 1925, i., 958.

For convenience of experiment we worked with an 8 per cent. solution of lecithin in chloroform, a 2 per cent. solution of cholesterol in chloroform, and a 0·0001 solution of ergosterol in chloroform. To exclude any possible effect of radiation on the lecithin itself when irradiated in solution with ergosterol, we irradiated the ergosterol in a quartz tube and then added the unradiated lecithin solution in equal volume. After evaporation, a drop of distilled, recently boiled, water, or normal saline. was placed on the film, which was then examined, covered or uncovered, under the microscope.

At this low percentage, in which the ergosterol lecithin ratio presumably corresponds with that existing in the living body, the effect of the irradiated as compared with the non-irradiated sterol is slight. The difference becomes easily recognisable when the strength of the ergosterol is raised to 0·001 per cent. and becomes very marked when the strength of 0·01 per cent. is reached.

The following experiment shows that the effect on the lecithin is due to vitamin D, and not to any peroxide of ergosterol which forms on the irradiation of the sterol in contact with the air.

If two films or smears of ergosterol are made on a glass slide and irradiated, one in the air and one through a film of water covered by a quartz slip, the air being thus excluded, only the irradiated sterol from the film protected against contact with the air activates the lecithin. The sterol irradiated in contact with air fails to do so.

The question arises whether we can associate these findings with the changes which can be observed in living cells as the result of exposure to the action of irradiated sterol. I have shown[4] that living leucocytes, when incubated in blood or in blood serum on a thin film of irradiated ergosterol in a closed cell, respond sooner and more strongly than corresponding cells incubated on an ergosterol film which has not been previously irradiated. The cells in the irradiated film show increased pseudopodial activity, and they elaborate droplets of iodophil substance sooner and in larger quantity than *the cells* in the non-irradiated film. I have also shown in earlier papers that this formation of iodophil substance depends on nuclear and cytoplasmic changes, especially in the perinuclear lipoid-protein membrane. The significance of this observation lies in the observed influence of certain fat-soluble substances on this perinuclear membrane, which is now believed to be composed, in part at any rate, of lecithin, possibly in combination with cholesterol and other proteid substances.

Thus we have some evidence, based on experimental and direct observation, which suggests that irradiated ergosterol (vitamin D) exerts its influence primarily on the lipoid rather than on the protein elements in the cell. In this way it renders the cytoplasmic and perinuclear lipoid membranes more permeable, and increases nuclear cytoplasmic interchange.

Does the irradiated sterol produce this change in the cell membranes as the result of an inversion of phase of the constituents in a fat-water emulsion, or does it reverse the orientation of the lecithin molecules, thus directing the hydrophil chemically active pole towards the exterior?

My observations, if applied to rickets, suggest that the vitamin D acts on the bone cells concerned in calcification and speeds up their calcium-phosphorus metabolism by acting on the lipin constituents (especially the lecithin moiety) of the cells, and by facilitating interchange through the pericellular and perinuclear membranes, enables these cells to extract the calcium phosphate from the blood.

If, as I hope, they can be confirmed, a further step will, I think, have been taken in the fuller understanding of the mode of action of one of the fat-soluble vitamins on the organism.

I desire to acknowledge the great help I have received from Mr. Frank Young in this investigation, and also from Prof. Leathes's Croonian Lectures, published in THE LANCET in 1925.

A CASE OF

ILEOCÆCAL INTUSSUSCEPTION WITH SPONTANEOUS REDUCTION.

By S. M. POWER, M.B. LOND., F.R.C.S. ENG.,
RESIDENT SURGICAL OFFICER, ANCOATS HOSPITAL, MANCHESTER.

A SOMEWHAT unusual case of intussusception was recently admitted to Ancoats Hospital, under the care of Mr. E. E. Hughes, with whose permission the following notes have been written.

A male child, aged 11 months, was seized with collicky abdominal pain at midday and vomited twice. He was taken to Dr. J. Scanlan, who found blood on his finger-tip after doing a rectal examination and diagnosed the case as one of intussusception. On arrival in hospital, examination revealed a quite definite tumour, of typical shape, to the right of and above the umbilicus, and also an emptiness in the right iliac fossa. This was at or about 6 P.M. The child at the time seemed very ill with intermittent abdominal colic, but subsequently quietened down considerably and did not vomit again.

Before going to the operating theatre I examined the abdomen and could find no tumour of any kind. The rectum contained fæces. The advisability of operation seemed doubtful, for I had not personally found any evidence in support of the diagnosis, save a definite history and the report of previous examinations. An enema was given, which produced a good result stained with blood and mucus. Laparotomy was decided upon, the possibility of spontaneous reduction being mooted but dismissed as highly unlikely. I may add that there were no purpuric or arthritic symptoms at this or any other stage of the illness.

On opening the abdomen I found the cæcum in its normal position, but both it and the last six inches of the ileum and appendix were deeply congested and œdematous. So altered was the appendix, that it seemed advisable to remove it.

The most curious feature of the case was that on taking a final review of the abdominal contents I discovered another, and obviously early, intussusception in the small intestine, about two inches long. There was no blueness or turgidity, so that this could not possibly have been the apex of the original one. It was reduced and the abdomen closed. At the time it did not seem justifiable to take out enough small intestine to make sure whether the second intussusception was the result of normal or retro-peristalsis. At the end of the operation 5 c.cm. of normal saline were injected into either flank and the baby was put back to bed with radiant heat and rectal salines. Recovery was uneventful.

I conclude with, I think, sufficient justification that this was a case of spontaneous reduction of an ileocæcal intussusception. Whether the second condition would have progressed or not it is hard to say. It is conceivable that, if retrograde, it may have been caused by the same retroperistaltic waves that produced the self-reduction. In any case, the tale seems worth telling; H. W. Carson[1] says that the spontaneous cure of intussusception is so rare that very few surgeons have seen a case and that the few recorded examples are almost legendary.

---

LIVERPOOL OPEN-AIR HOSPITAL FOR CHILDREN.—The annual report of this hospital, at Leasowe, Cheshire, states that an important advance in the treatment of crippling disease in childhood has been made by the opening of the new treatment block. The chief feature of the building is the artificial light department in which carbon-arc and mercury-vapour lamps of the latest pattern are installed to provide general light treatment for 12 lying or 50 sitting cases per hour; as it is possible to work these lamps for five hours a day, the needs of the 200 children in the hospital can be met adequately. The patients stay for periods varying from three months to nine years.

BRITISH MEDICAL ASSOCIATION.

ANNUAL MEETING IN MANCHESTER.

(Continued from p. 284.)

SECTION OF MEDICINE.

CARDIO-AORTIC SYPHILIS.

Prof. GEORGE MURRAY (Manchester) presiding, Dr. JOHN COWAN and Dr. J. STEVEN FAULDS (Glasgow) opened a discussion on Syphilis of the Heart and Aorta. They began by quoting estimates of the incidence of syphilis in the general population. Osler and McCrae had long ago estimated an incidence of 12 per cent. for Berlin and 15 per cent. for Paris. The speakers gave an estimate, based upon Wassermann reactions among their own ward cases, of 8·6 per cent. in males and 7·2 per cent. in females. Carey Coombs's figures were 9 per cent. in hospital and 4 per cent. in private patients. The incidence of syphilis among patients with defective hearts was estimated by Allen at 19·7 per cent.; Dr. Cowan and Dr. Faulds found it to be 17·7 per cent. when based upon Wassermann reactions of their patients, while if the diagnosis was based upon naked-eye pathological findings the incidence was 15·3 per cent. All these estimates probably erred upon the conservative side.

Pathological Lesions.

The pathological lesions recorded were those observed in a thousand consecutive necropsies; of these, 390 presented some disease of the heart or aorta, 60 of which were considered to be due to syphilis. The lesions found were endarteritis obliterans, aortitis, aortic valve disease, gumma, and myocardial fibrosis.

Endarteritis obliterans affected short lengths of vessel, but in their whole circumference, always narrowing the lumen and frequently accompanied by thrombosis. The interna and adventitia were always thickened and showed new-formed elastic tissue, the media being either thinned or little altered. Gross calcareous or fatty changes were rare. Prof. R. Muir held the opinion that the lesion represented the reaction to an irritant approaching the arterial wall from without. Endarteritis obliterans was characteristic of syphilis in all its stages, and was the important primary change in aneurysm and myocardial ischæmic fibrosis.

Specific Aortitis.—These lesions occurred as soft, gelatinous, greyish elevated plaques of considerable thickness, which might coalesce and later become contracted, thinned, and pearly white. The first part of the thoracic aorta was the site of election. The early lesions started in the adventitia and involved the nutrient arteries of the aortic wall, giving rise to weakening and resorption of the media with consequent weakening of the aortic wall. This process led to potential or actual aneurysm. The aortic cusps and the coronary vessels might be involved, but lesions of the mitral valve segments were insignificant and played no proportionate parts in the production of chronic mitral disease.

Aneurysm might possibly be produced by weakening of the aortic wall by ulcerative processes other than those of syphilis, but was most commonly of specific origin.

Chronic Aortic Valvular Disease.—The pathological lesions were admittedly very varied, the causes multiple, and the results upon the valve more dependent upon the site of the injury than on the cause. Valve lesions could take various forms, and their ætiology could not easily be determined.

Atheroma was by far the most common vascular lesion, peculiarly liable to attack vessels of the heart, brain, and limbs with the aorta. The causes were general, arising in the battle of life and accompanying increasing years. Atheroma is often present in addition to rheumatic and specific infections, making the resultant lesion impossible to classify.

Myocardial disease was mostly only a side issue. The occurrence of a true syphilitic myocarditis, or of localised gummata, was rare, the myocardial changes being for the most part the secondary effects of coronary occlusion and, therefore, not in themselves specific, but dependent upon the degree of occlusion.

Pericarditis of syphilitic origin was hardly ever seen, though cases of proliferative mediastino-pericarditis, taking origin beneath the diaphragm, might occur.

The Clinical Data.

Aortitis of the infective type was chiefly caused by syphilis; the lesion per se produced no symptoms even when extensive in area and advanced in degree. Patients suffering from large aneurysms, extensive aortic valve lesions, and coronary infarcts were able still to carry on their employment. Although the symptoms of specific heart lesions were similar to those arising from any other cause, paroxysmal attacks of pain and dyspnœa at night were more common in the specific than the rheumatic group, owing to the coronary involvement. In the syphilitic group continued pain was suggestive of aneurysm rather than pericarditis; palpitation was due to throbbing vessels rather than to abnormal rhythm, and œdema to local pressure rather than the effects of gravity. The appearance of the patients was thin, emaciated, and sallow, abnormal pulsation sometimes appearing above or below the clavicles. A systolic aortic murmur often preceded a diastolic one, although aortic stenosis was rare; the second aortic sound was increased and the radiogram showed an increase in the aortic shadow.

The association of aneurysm with syphilis was stressed by Dr. Cowan and his collaborator; in a series of 66 cases of chronic aneurysm 49 were found to be syphilitic. The age-incidence both of syphilitic heart disease and of aneurysm was from 40 to 60; both tended to occur 10 to 20 years after infection, although cases had been recorded within 12 months of primary infection.

Chronic aortic valve disease was regarded as due to syphilis in 30 per cent. of a series of 274 cases; but there was a sex difference, the incidence being over 30 per cent. in males and under 20 per cent. in females, and also an age difference, the percentage rising to 50 between the ages of 40 and 60 in males. The incidence of syphilis and rheumatism in the series was the same, but the incidence of aortic disease in men between 40 and 60 with no antecedent history was very suggestive of a specific origin.

The physical signs differed little in the two groups, but accentuation of the pulmonary second sound, common in rheumatic cases, was rare in the syphilitic group, since rheumatism commonly, and syphilis rarely, affected the mitral cusps. Evidence of aortic aneurysm or dilatation of the aorta suggested a specific origin of the lesion, but the final diagnosis might frequently depend upon the recognition of stigmata elsewhere or a positive Wassermann reaction. Not only mitral valvular disease but acute endocarditis was rare in syphilis, while in the rheumatic group reinfection from acute endocarditis may occur and leave unmistakable signs at necropsy.

Myocardial Disease.—Examination of the series of cases failed to give any estimate of the frequency of syphilis as a causative factor in myocardial disease; the age-incidence was a decade later than that usual for syphilis. The conclusion arrived at was that the degree of coronary damage was a much more important factor than the original cause of the disease.

Angina.—The relation of syphilis to angina was discussed. The speakers considered the physiological basis of the pain to be the relative anoxæmia of the cardiac muscle. Seven necropsies were recorded in three of which specific aortitis was found. They pointed out, however, that the average age of incidence was a decade later than that for specific aortitis.

Diagnosis.

Dr. Cowan and Dr. Faulds said that the four great causes of cardiac lesions were rheumatism and bacterial endocarditis in the earlier years of life, involving the valves and pericardium, and syphilis and atheroma in later life, involving the valves and arteries. Syphilis must be recognised as an important cause of heart disease, occurring most frequently in males between 40 and 60, the symptoms being entirely cardiac. Aortitis and aneurysm were usually, aortic disease, myocardial disease, and angina frequently, syphilitic; mitral disease and pericarditis were never syphilitic.

The clinical history might mislead; the Wassermann reaction, if positive, was important, but if negative might mislead, since 25 per cent. of cases of syphilis might give a negative reaction in the tertiary stage, though a full routine examination might reveal other definitely specific stigmata to complete the diagnosis.

Treatment.

Treatment of cardiac lesions as such differed in no way from that of similar lesions of other origin. From the constitutional point of view, the disease was still active and required active treatment. The choice between the sterilisation by arsenical compounds and the older method of administering a long course of mercury and iodides must be made.

The speakers held that the older long-continued method was much to be preferred, except in those patients who showed no signs of cardiac deficiency; but they stated with emphasis that the true treatment of cardio-aortic syphilis was preventive, every case which occurred nowadays being due to error, either on the part of the patient or on that of his medical adviser.

Discussion.

Dr. S. Boyd Campbell (Belfast) confined his remarks to the serum reactions in the blood in cases of cardio-aortic syphilis, with the changes resulting from treatment. Among 55 cases of aneurysm the Wassermann reaction was found negative in 11. Variations in the results were found by various techniques. The degree of positiveness was usually slight, while provocative N.A.B. injections rarely produced any change. A series of graphs were shown recording the positive units by the Dreyer method before, and during, treatment; several showed a considerable fall, in some cases to negative, followed by a slight rise. The records extended over varying periods up to four years. The method of dosage remained constant, small amounts of N.A.B. up to 0·4 g. were given, accompanied by the continued exhibition of mercury and iodides. Another series of graphs showed a marked rise in the serum reaction as the result of the first course of treatment, followed subsequently by a fall almost to normal. Two cases were recorded where a superimposed bacterial infection in a treated case occasioned a sudden rise in reaction with death. Treatment had originally been undertaken in those cardiac patients who responded badly to treatment on general principles. They showed material improvement under antispecific treatment, but only if the first part of the treatment was carried out while the patient was confined to bed. Dr. Boyd Campbell believed that once treatment had begun it must be maintained for the rest of life, and that probably two courses per year would always be required.

Dr. J. Crighton Bramwell (Manchester) confined his remarks to the disturbances of the cardiac mechanism. He said that it was difficult to find an adequate criterion of the syphilitic origin of a lesion. In premature ventricular contractions, for example, tea, coffee, tobacco were known to be capable of producing the arrhythmia in susceptible subjects. The presence of a positive Wassermann reaction proved nothing. Where groups of ventricular extrasystoles occurred and disappeared under antispecific treatment, the possibility of a syphilitic origin had to be considered. Paroxysmal tachycardia was known to be rare in cardio-aortic syphilis. Dr. Bramwell said that in 26 of his own cases where the nature of the arrhythmia had been established by the electrocardiogram no clinical evidence of syphilis had been obtained, and similar findings had been reported by other workers. Heart-block had in the past been regarded as most frequently due to syphilis, but increased knowledge had shown this to be wrong. In his own series of 23 cases clinical evidence of syphilis was found only three times, and these summed with other records in the literature gave 105 cases, with syphilis as a cause in 20. Heart-block of high grade, even causing Stokes-Adams attacks, might occur in paroxysms. There was on record a case where the heart was observed to change from normal rhythm to complete heart-block with convulsive seizures on two days out of eight, and then to return to normal rhythm. These attacks were attributed to a pyrexia with joint pains which occurred almost simultaneously. Auricular fibrillation arose from three main causes: (*a*) rheumatic infection of long standing; (*b*) degenerative myocardial fibrosis; (*c*) toxæmia as in thyroid disease. There was no evidence that syphilis was likely to be a common cause. Dr. Bramwell had come to the conclusion that heart-block was the only disturbance of cardiac mechanism which was frequently due to syphilis, the condition of pulsus alternans being common to all degenerative cardiac changes.

Prof. A. S. Warthin (Michigan) spoke of the histological findings in syphilis, particularly those in the heart muscle. He recalled the fact that cardiac myxo-gumma was first referred to in 1826, the observation remaining unnoticed until his own corroborative work many years later, when a similar condition was found in a congenitally syphilitic heart, and he was able to demonstrate large numbers of spirochætæ in the gelatinous areas scattered throughout the ventricular wall. Prof. Warthin showed a series of microphotographic lantern slides to demonstrate the histological changes of acute exacerbations of syphilis in the ventricular myocardium of two patients who died with dramatic suddenness; death in early life was due to congenital syphilis, and that in later life to the acquired disease—in both cases when the disease had existed for 20 years. Each series of slides was introduced by a short résumé of the clinical history; then slides of the macroscopic appearance were followed by those illustrating microscopical changes under progressive degrees of magnification up to the tissue reactions around the individual spirochæte. The yellowish, semitranslucent, gelatinous patches of the macroscopic lesion, the proliferation of all nuclei in the affected area, the multiplication of the single nuclear tissue cells, the intercellular œdema, the want of change in the majority of the muscle-fibres, the vacuolation and œdema of the connective tissue with proliferative thickening of the endocardium were clearly represented. Prof. Warthin stated that 20 to 60 per cent. of all post-mortem material at his hospital showed definite evidence of latent syphilis in which the spirochæte could be demonstrated. He pointed out that such lesions as had been shown could be found in the wall of the left ventricle at its junction with the septum in every male case of syphilis, but that this was not true of the female.

Dr. F. Parkes Weber (London) asked Prof. Warthin what were the Wassermann reactions in his cases of syphilitic myocarditis, and also whether cases of thoracic aneurysm had been found due to any disease other than syphilis, particularly in young people. Aneurysms of cerebral vessels were known to give rise to sudden severe cerebral hæmorrhage before the age of 30.

Dr. J. Speares (Dublin) reported a high frequency of positive findings of aortic aneurysm by routine X ray examination of heart cases, having found thoracic aneurysm in 42 instances among 600 cardiacs, with vocal cord palsy in 13 instances. Among this group the Wassermann reaction was found to be negative 15 times. Tracheal tug as a physical sign was criticised, the speaker only having found it present once in 61 cases of thoracic aneurysm. He considered the value of the Wassermann reaction in cases of myocardial damage to be very doubtful owing to the total want of correspondence between the clinical and pathological findings.

Dr. D. NABARRO (London) reported the occurrence of chorea and rheumatic heart disease in a child aged 8 at the Hospital for Sick Children, Great Ormond-street, who developed keratitis while under treatment. He was found to have Hutchinson teeth and a strongly positive Wassermann reaction, and under adequate antisyphilitic treatment made an almost complete recovery, including a negative Wassermann reaction.

Sir HUMPHRY ROLLESTON pointed out that the lesions found in the acute exacerbations of visceral syphilis were in their nature secondary rather than tertiary syphilitic phenomena. He asked how far to-day syphilis might be regarded as actually cured by modern treatment, in view of the continued record of reinfections.

Dr. H. J. STARLING (Norwich) discussed the indications for Wassermann test in heart disease. He considered that aortic valve lesions, pallor, wasting, and a grade of illness disproportionate to the lesions found, or a reluctance to recover, all called for this investigation. He reviewed the coexistence of syphilis with other infections, and the possibility of exacerbation from any active sepsis in the course of active antisyphilitic treatment.

Prof. JOHN HAY (Liverpool) criticised the discussion on the grounds that although syphilis might be the original cause of a cardiac lesion, yet the illness from which the patient suffered and for which treatment was sought was cardiac failure. It followed that to treat the antecedent syphilis might do harm rather than good, while to deal with the essential symptoms of circulatory insufficiency was the essential clinical demand. He suggested that a percentage of 30–60 of all hospital autopsies showing definite signs of syphilis was one three or four times greater than anything accepted as probable in this country. He asked Prof. Warthin for any possible explanation of this discrepancy and also for any data to estimate the cardiac reserve in that series of cases reported by him in which dramatically sudden death occurred and revealed at autopsy a widespread generalised syphilitic myocarditis.

Dr. G. J. LANGLEY (Manchester) reported the Wassermann results from cases in his own cardiac clinic. The only case of thoracic aneurysm occurring in the past ten years which gave a negative Wassermann test was found at post-mortem to have no aneurysm. Aortic disease constituted 12½ per cent. of all cardiac lesions. 42 per cent. were rheumatic and 35 per cent. syphilitic; 18 per cent. showed thoracic aneurysm. Myocardial degeneration, as shown by a form of electrocardiogram differing widely and grossly from normal, occurred 43 times, of which the Wassermann reaction was positive three times in 16 cases. In nine cases of complete bundle-branch block the Wassermann reaction was only partially positive in one, being negative in all the others. Dr. Langley did not, therefore, regard syphilis as being the usual cause of gross myocardial disease.

Prof. WARTHIN, in reply to various inquiries, stated that 40 years ago the State of Michigan as a lumber camp was infected with a peculiarly virulent type of syphilis, which might explain the very high percentage of findings at the autopsies of to-day. He reiterated his figures of 30–60 per cent. of syphilis for all hospital autopsies. He stated that even with the special Kahn test, much less with the ordinary Wassermann test, many results were negative in cases which later were proved histologically to be syphilitic; even in such diseases as thoracic aneurysm the Wassermann reaction and Kahn test were not unc[illegible]nly both quite negative. He discussed the [illegible]in of syphilitic histological changes in the [illegible]lis was common in the testis, but was never found in the ovary; it was common in the heart, central nervous system, and aorta of man, but rare in woman. He further stated that syphilis tended to remain entirely latent in women till after the menopause, when acute exacerbations were common. His experience of actual cure was that it never occurred. Treatment must be maintained certainly for five years, and probably longer; immunity might be established, but probably not for all strains of the spirochæte. Reinfection so-called could be explained on two heads: (1) The second chancre was not a true chancre; in some cases he had demonstrated the absence of spirochætes, the lesion being septic in origin. (2) In other cases, the reinfection was due to another strain of the organism. He knew of only two causes for thoracic aneurysm: syphilis, and the *Streptococcus viridans* of bacterial endocarditis.

SECTION OF NEUROLOGY AND PSYCHOLOGICAL MEDICINE.

THE VOLUNTARY BOARDER.

Prof. JUDSON S. BURY (Manchester) presided over this Section.

Dr. HENRY YELLOWLEES (London) opened a discussion on the present position of the voluntary boarder. He said that there were three classes of "mental" institutions in this country: the county or borough establishments for rate-supported patients, the privately owned "licensed houses," and the registered mental hospitals. In addition to rate-aided patients, many of the county asylums could, and did, admit paying patients at a low figure, but no patient could be admitted to these institutions unless he had been certified and a magistrate's order for his "detention" obtained. This was probably the greatest blot on our present lunacy administration. Only the licensed houses and the registered hospitals received voluntary boarders. A voluntary boarder was a person who entered the institution on his own request, and was free to leave it at 24 hours' notice, should he desire to do so. The all-important statement must be added that a voluntary boarder might only remain under care so long as he was definitely desirous of doing so and capable of expressing his desire. In other words, expressed willingness to remain was the sole criterion of a patient's suitability to stay in a mental hospital on a voluntary basis. A very profound degree of mental disturbance was quite compatible with a wish to remain under care, but in practice this was not considered. So long as the patient wished to stay in hospital he remained a voluntary boarder, and therefore a legally sane man, whatever his symptoms might be. Once let this willingness to remain falter, disappear, or fail to be expressed, and the patient must be certified as of unsound mind. There was no more pitiable *reductio ad absurdum* than this, that the deciding factor as to a person's legal sanity or insanity was simply whether or not he could express a desire to remain in hospital. It took for granted that the patient meant what he said, and would not say what he did not mean.

A more important question was that of the patient who, having entered a mental hospital of his own accord, became, owing to illness, incapable of expressing his wishes one way or another. It was this problem of the non-volitional case which had always been the centre of controversy, and had led to the familiar criticism that if a patient, fearing an acute mental attack, entered a mental hospital, he would not be permitted to remain when the very illness for which he sought care supervened, should it render him incapable of expressing his wishes. Also, it must be noted, that the cause of the patient's lack of volition had nothing whatever to do with the case. Should a patient suffering from the nervous and mental after-effects of, say, concussion, seek admission, and subsequently lapse into unconsciousness, there was not the faintest doubt that, as the law stood, he ought to be either certified or removed. And if this was so, how much more was it true of confused patients, of irritable, excited patients, of patients who were swayed hither and thither by constantly varying delusional fancies, and of melancholics whose entire loss of volition and querulous objection to deciding anything were among their fundamental symptoms? All such patients, and many others, said the law, must be removed or certified.

The Interpretation of the Law.

Our Lunacy Act said very little indeed about voluntary boarders. So far as it concerned itself with them at all, it regarded them purely from the point of view of the liberty of the subject. It looked on them as people who had taken the risk of jeopardising their personal liberty and must be safeguarded from any unscrupulous persons who might attempt to take advantage of this fact. The conception of a voluntary boarder as a sick person seeking advice, treatment, and care in a medical establishment was utterly foreign to the Act. The unenviable task of interpreting and administering the law as to voluntary boarders fell on the Board of Control, and, taking it all over, the result was such a reasonably broad and common-sense interpretation that all concerned had cause for thankfulness. The voluntary boarder had particular cause for gratitude. Among many other things, the Board of Control did all it properly could to avoid or postpone the certification or removal of the non-volitional case. When there was any ground for expecting return of volition in a reasonable period a week or two's grace was usually granted, particularly when, as almost always happened, the relatives urgently desired it. Nevertheless, the non-volitional patient could not legally remain in a mental hospital. That was the crux of the whole matter; it was the problem which had so far proved insoluble, and seemed likely to remain so until the public view of mental illness and its treatment had been completely re-educated and the law entirely recast.

Alternatives to Certification.

Assuming that care and treatment at home were impracticable, as they were in a majority of cases, there was no alternative to certification. There were, however, two other possibilities which might be legalised. First, it might be made legal to retain such a patient in a nursing home, "free from the taint of lunacy." Dr. Yellowlees mentioned this only to condemn it. To begin with, he said, why should the nursing home be given authority to retain certifiable patients without certificate when such authority was withheld from the mental hospital? Further, such a course would deprive the patient of what was incomparably the best means of treatment for him. There was no form of disposal for mild or severe mental cases to compare for one moment, as regards efficiency, economy, and results with residence in a modern mental hospital. The speaker had held that view when he was a medical superintendent. He held it equally firmly and expressed it more readily now that he was no longer engaged in institutional work. Secondly, it might be made legal to retain uncertified in the mental hospital a voluntary boarder who had become non-volitional. This was the ideal, but how it was to be contrived was hard to see. In the present state of public opinion, Dr. Yellowlees confessed he could imagine no workable system of "safeguards" which would be likely to meet with general acceptance. The best that the Royal Commission could suggest was an elaborate process of provisional certification. It was a clumsy sort of compromise which would have been unworkable, and in any case did not meet the difficulty. As things were, however, there was no alternative to certification if the voluntary boarder who had become non-volitional was to remain. One practical difficulty immediately presented itself. If the patient was certifiable, and his relatives wished him to remain where he was and were content that he be certified, was it fair to proceed with this and retain him as a certified patient? A majority of the public regarded it as a gross breach of faith in the case of a patient who wished to leave. Many mental hospitals went the length of refusing to keep as certified those who had been with them as voluntary boarders, and there was something in this as a gesture, though it was hard to see what principle was involved.

The process of certification should not be necessary, but it would remain so until we had provided a more satisfactory alternative, and, in particular, until we had solved the problem of the non-volitional case. That it was utterly distasteful to both the lay and medical public there was not the slightest doubt. A large majority of the public regarded avoidance of certification as the first and greatest consideration in mental illness. This was in many ways a pity. There was much to be said in favour of certification in many cases, even under the existing law, and most of the public horror of it was the result of ignorance and prejudice.

The Grading of Patients.

The dread of "asylums," as apart from the mere process of certification, was of course what affected the intending voluntary boarder, though to a much less degree, strangely enough, than it did the relatives of the certified patient. It was the old question of "grading" which was at the bottom of it all. The extraordinary variety in the symptoms and needs of the patients admitted to a central hospital of any size, along with the constant dead weight of irrecoverable chronic cases, presented a problem which needed—among many other things—almost unlimited space, staff, and money for its solution. For some years he had been convinced that this difficulty was being met in the wrong way—namely, by keeping mild cases away from the mental hospital, which, with all its drawbacks, was infinitely the best place for them. Dr. Yellowlees had long thought that we should begin at the other end, and remove to completely separate and independent branches of the mental hospital the chronic, unpleasant, and noisy cases. It would need more than two separate establishments to do the thing ideally, and, of course, the branches, though entirely separate, would have to be near enough for quick and easy interchange of patients. A scheme of the kind was actually in preparation in London just now, the pioneers being the Governors of St. Luke's Hospital. When completed, the reorganised St. Luke's would consist of three separate establishments, one in London and two near it—one of them for quiet, recent, coöperating patients; the second for noisy and troublesome acute cases and irrecoverable chronic ones; and the third for convalescents. He mentioned this scheme, not to discuss it, but to show what could be done and was being done in the face of quite extraordinary difficulties. It was to the general body of the profession that we might fairly look for help. There could be no better outlet for the organised activity of the profession and of the B.M.A. than a combined effort to bring just a little more science, broadened humanity, a little more practical good sense, into our dealings with sufferers from the saddest of all human ills.

Conditions in Scotland.

Prof. G. M. ROBERTSON (Edinburgh) said that while Dr. Yellowlees had restricted his observations on laws and practice to those prevailing in England, he (Prof. Robertson) proposed to supplement his remarks by an account of the laws and practice in Scotland. The experiment of treating patients suffering from mental disorders voluntarily was first tried in Scotland in 1862. The voluntary patients who were admitted to mental hospitals in Scotland under the 1862 Act were all of unsound mind, and any person could be admitted as a voluntary patient provided he made a written application to that effect. After admission to a mental hospital he might continue to enjoy the status of a voluntary results in later childhood and puberty could be prevented. Whilst the diagnosis of adenoids might be easy in the hands of the expert there were a large number of cases where the mass of adenoid tissue removed at operation was out of all proportion to the symptoms present. Hence their removal was important in every suspected case. The conditions in the patient calling for the services of the expert were: mouth-breathing, respiratory catarrhs, all aural conditions from deafness to otitis media, recurrent and persistent febrile attacks with no other cause, and a familial tendency to adenoids which was notable especially among Jews. The diagnosis of tonsillar enlargement was usually easy; the difficulty was to know when to operate and when not to operate. Local medicinal treatment could do much good in some cases; it might lead to a fibrosis of the tonsillar tissue analogous to that occurring normally at 14 to 16 years of age. If, after one attack treated medically, there was one relapse, then the tonsils should be removed. In conclusion, Dr. Goodfellow spoke strongly against the (in his opinion) almost unjustifiable removal of tonsils and adenoids in the out-patient departments of hospitals, and condemned the practice of allowing children to go home a few hours after operation.

Miss **GERTRUDE HERZFELD** (Edinburgh), speaking as a general surgeon, said she was interested in the relationship of tuberculous cervical glands to tonsils and adenoids. During the last five years 646 cases of cervical gland tuberculosis had been dealt with by radical operation at the Edinburgh Children's Hospital. In a large number of these the tonsils appeared healthy and not enlarged, and therefore they must have failed in their protective function. The tonsils had been examined histologically in her last 17 cases, and in 9 of them signs of early tuberculous infection were present. Cervical tuberculous glands, she said, very rarely appeared after tonsillectomy for simple hypertrophy, so that this operation at an early age might prevent the development of such infection in later childhood. Other children who required tonsillectomy were those with simple enlargement of the cervical glands, those who had had pneumococcal or other infections which might reach the blood stream through the tonsils, and those who suffered from general weakness and hypotonia, as shown, for instance, by flat-feet. The diagnosis of adenoids was not always simple. The possibility of a retropharyngeal abscess should always be borne in mind, and digital examination carried out in all doubtful cases, especially those of short duration. In Miss Herzfeld's opinion skilful removal of the tonsils with the guillotine was the best method of tonsillectomy.

Dr. **DAVID NABARRO** (London) gave the result of some investigations carried out by Dr. R. A. Macdonald and himself. The organism of rheumatism was often said to be found in the tonsils. They examined bacteriologically the streptococcal flora in 50 tonsils removed from rheumatic children and 48 from non-rheumatic patients. Whilst admitting that the classification of streptococci was not yet very satisfactory they did not find any marked difference in the streptococcal flora of the two groups; in other words, the rheumatic cases could not be told from the non-rheumatic ones. Although tonsillectomy was of value in acute rheumatism the causal streptococcus had not yet been established. The considerable difference of opinion amongst investigators made it very difficult to correlate their findings. It was probable that the soil was more important than the seed and hypersensitiveness to streptococci might be the cause. The tonsils might well be the place where repeated small doses of infection occurred giving rise to this hypersensitiveness. Thus tonsillectomy in rheumatic cases was probably a valuable therapeutic and prophylactic measure.

Dr. **JEFFREY RAMSAY** (Blackburn) said that infected tonsils were a potential or actual source of danger to their owners. Sometimes it was hard to say whether the tonsils were infected or not, and it was in such cases that tonsil puncture, devised by Dr. C. M. Pearce and himself, was most useful. He described the details of his method and pointed out that both tonsils should be examined, since one might be healthy and the other diseased. In over 60 per cent. of cases he was able to obtain streptococci in culture. Hence the method was of value for the detection of these cases, and by the removal of these tonsils rheumatism could be prevented. Tonsil puncture was valuable, too, in the detection of cases of diphtheria "carriers." He quoted one case where a swab from the surface of the tonsil yielded but a feeble growth of diphtheria bacilli, yet tonsil puncture showed the presence of very virulent organisms.

Dr. **F. C. EVE** (Hull) demonstrated his method of tonsil suction by means of his simple instrument. By suction the tonsil could be turned inside out and the pus obtained could be shown to the patient. He also showed another instrument, for therapeutic use, by means of which, he claimed, the tonsillar crypts could be cleared out and disinfected. Tonsillectomy was admittedly the better treatment, but was often out of the question, especially in adults. If septic tonsils were cleaned out by a course of suction before enucleation the danger of hæmorrhage could be minimised. His simple instruments afforded the general practitioner an opportunity, diagnostic and therapeutic, which was not available to him before.

Mr. **DENNIS BROWNE** (London) doubted if the tonsil had any defensive mechanism. Further, it was not possible to say whether nasal catarrh was due to adenoids or caused the adenoids, or whether both were due to a common cause. Turning to the choice of operation for the removal of tonsils he insisted most strenuously that the method of dissection was superior in every way to the guillotine.

Mr. **F. H. DIGGLE** (Manchester) advised against digital examination of adenoids because it frightened the children, and said that in his experience, too, adenoids did recur after efficient operation. Tonsils and adenoids might subside with efficient nasal hygiene and never recur, though nasal drill and hygiene in his hospital practice had not had beneficial results. Mr. Diggle used both the method of dissection and the guillotine. Even after complete removal of the tonsils freedom from further sore-throats could not be guaranteed.

Dr. **H. BRACEY** (Warwick) spoke from the point of view of the school medical officer. Slight rickets, a bad stance, flat feet, and a general flabbiness of the body and even some flabbiness of the mind might result from diseased tonsils and adenoids. He asked Mr. Jones if he had met with cases of adenoids in which the only symptom was headache.

Dr. **ESTHER CARLING** (Berkshire) said that she had charge of a small sanatorium for potentially tuberculous children. Many of them suffered from diseased tonsils, and in her experience the improvement obtained after removal of the tonsils and adenoids was very gratifying. There was no doubt that many children were labelled as suffering from suspected tuberculosis when they were really suffering from tonsils and adenoids. Dr. Carling joined with Dr. Goodfellow in declaiming against the practice of removing tonsils and adenoids in the out-patient departments of the hospital, with early despatch home.

Dr. **C. P. LAPAGE** (Manchester) expressed his belief that tonsils and flat feet were associated, the flat feet resulting from the hypotonicity consequent upon the toxæmia occasioned by the tonsillar sepsis. In heart disease, too, there was a condition of toxæmia, and it was not wise to refer to such cases under the term of chronic rheumatism. Post-operative general medical measures and nasal hygiene were matters of considerable importance.

Dr. **H. T. ASHLEY** (Manchester) said that all tonsils and adenoids did not require removal, though in suitable cases there was no more important operation. The incidence of sore-throats in a small rheumatic clinic under his charge was very high, although nearly all the children had had their tonsils removed.

Prof. C. W. Vining (Leeds) after enumerating the diseases in which he considered removal of tonsils beneficial, said that in rheumatism the operation had no considerable value. Removal of the adenoids did not prevent chorea. In asthma, enuresis, glandular fever, tuberculous glands, or recurrent pneumonia he had not seen benefit from tonsillectomy. He decried the present tendency for the wholesale removal of tonsils and adenoids in school-children.

Dr. S. Stephenson *put in a strong plea against* children going home soon after operation at the hospital out-patient department, and after Mr. Arnold Jones had briefly replied to the discussion, a resolution was passed by the meeting to the effect that removal of tonsils and adenoids in children should not be done as an out-patient operation, and that provision should be made for them to be kept under observation for at least 48 hours.

Reviews and Notices of Books.

Causes and Prevention of Maternal Mortality.

By Henry Jellett, B.A., M.D. Dub., F.R.C.P.I., Consulting Obstetrician to the Ministry of Health, New Zealand; Consulting Gynæcologist, Rotunda Hospital, Dublin; late Master, Rotunda Hospital. London: J. and A. Churchill. 1929. Pp. 300. 15s.

This book is a contribution towards the reduction of the rate of maternal mortality. The views expressed are based upon the author's experience as Master of Rotunda Hospital and in the practice and teaching of obstetrics and gynæcology in Dublin as well as on that gained in his present position of consulting obstetrician to the Department of Health, New Zealand, where he is attempting to tackle the problem of the high maternal mortality-rate in New Zealand.

In this volume Dr. Jellett deals amongst other related subjects with the care of the pregnant woman, the education of the maternity nurse and midwife and of the medical adviser, the equipment of the private maternity hospital, and the general management of labour and the puerperium. Interesting, and to British readers, unflattering comparisons are made between the training of medical students in certain continental countries, especially Holland, and that in the medical schools of Great Britain and Ireland. In the University of Utrecht, for example, where the length of the medical course is six years, instruction in theoretical midwifery begins in the second year and continues during the third, fourth, fifth, and sixth. By the end of the fourth year the student has already had over 500 hours teaching in theoretical midwifery! In the fifth and sixth years the teaching is mainly clinical, but still eight hours weekly are, in addition, devoted to special instruction in practical obstetrics. In Amsterdam University "the number of teaching hours in obstetrics is equal to that in general surgery." Is it a coincidence that the maternal mortality-rate in the British Empire, including New Zealand and Australia, is 4·22, whereas in the Scandinavian countries and Holland it is only 2·53 per 1000 live births? Dr. Jellett believes that no scheme will go far towards reducing maternal mortality in this country until midwifery is allotted in the medical curriculum a place at least equal to that of surgery, but that when the training of the doctor is adequate, a scheme in which antenatal supervision is carried out by the doctor and normal labours are conducted by the midwife, with the medical practitioner, specialist, and hospital facilities available when necessary, will go far to solve our high maternal mortality-rate. The doctor he considers an unsafe accoucheur for normal cases, first, because he is liable to carry infection, and secondly because he is liable to be in a hurry, and therefore the two essentials of midwifery—asepsis and the avoidance of interference—are crowded out. The reader may well ask how the general practitioner is to acquire special skill if he only sees abnormal cases, or how he is to be rendered safe for abnormal cases if his contact with infected wounds in practice is liable to cause him to infect cases that are normal. Clearly the patient whose labour turns out to be abnormal is doubly unfortunate.

Referring to the methods of Dr. I. W. Potter (of *Buffalo, not of New York) à propos of* unnecessary interference with labour, Dr. Jellett states that in every case he "dilates the cervix manually shortly after labour begins, turns the normal vertex presentation into an abnormal foot or feet presentation, and extracts the child." In fairness to Dr. Potter it should be stated that he does not interfere until the os is fully dilated. In a final chapter on the causes and prevention of maternal mortality Dr. Jellett sums up what he believes to be the essential points to which future effect must be directed—viz., efficient medical education in obstetrics, efficient training of midwives and maternity nurses, the improvement of maternity hospitals, the general recognition of the facts that labour must be carried out under aseptic conditions, and that it is not permissible to interfere with normal labour, and, finally, antenatal supervision and care. In the latter it is essential that "the patient should find a sympathetic atmosphere in order that she may learn to view the clinic as an advisory centre where her various troubles are always willingly considered."

The book is written in vigorous style, and deserves to be read by all who are interested in an improved midwifery service.

Epidemiology Old and New.

By Sir William Hamer, M.A., M.D., F.R.C.P., formerly Medical Officer of Health and School Medical Officer, County of London. London: Kegan Paul, Trench, Trübner and Co., Ltd. Pp. 180. 9s.

In this book Sir William Hamer has brought together the views on epidemiology which he has so often expressed in the annual reports of the L.C.C. and in contributions to the proceedings of learned societies. Those who are familiar with the work will probably agree that the title might well have been "Old Epidemiology Rediscovered," for, although the author reveals by casual reference his familiarity with the work of the newer epidemiologists, the main trend of the argument is toward showing that Sydenham had got hold of most of the truth and that the particularism of the nineteenth century closed our eyes to the fundamental immutability of the laws governing the rise and fall of epidemics. Repeatedly, therefore, attention is directed to the remarkable similarity of the "epidemic constitutions" at the end of the seventeenth century and the "settings" of influenza in our own times.

The book opens with a review of epidemiological thought from Sydenham to to-day. Chapters follow upon the recent influenzas, contrasts and resemblances between the epidemics in London of Sydenham's *time and the present day, the germ theory, and* a plea for return to the Hippocratic method. Historically, influenza is shown to be an endemic disease with periods of violent epidemic exacerbation preceded and followed by outbreaks of fever with local manifestations in the cerebro-spinal system. It is maintained that these "settings" are so constant that the variants, influenza, cerebro-spinal fever, polio-encephalitis, and poliomyelitis and lethargic encephalitis ought not to be regarded as separate, specific diseases. Sir William seems to have little faith in the theory that the micro-organisms hitherto identified are the main cause of the communicable diseases, preferring to describe them rather as "associated organisms," but he gives no valid explanation of the constant relation of a definitely recognisable micro-organism such as the meningococcus with a definite clinical entity such as cerebro-spinal fever. While his broad generalisations will be hard to refute, his attitude to bacteriology is surely too iconoclastic. There may be a middle view. It is conceivable that, just as vaccinia may predispose to an infection causing encephalitis, the diseases known as cerebro-spinal fever, poliomyelitis, and epidemic encephalitis may become prevalent as the result of a symbiotic association of the micro-organism concerned with the virus of influenza in some particular phase of its life-history. Moreover, the modern theory of the epidemic could not have been formulated without investigation which depended upon knowledge arrived at primarily by laboratory methods. It is true, however, that the obsession of the professional mind with micro-organisms made it difficult for a small band of epidemiologists in the latter half of the nineteenth century to keep their confrères alive to broad epidemiological conceptions such as those of Sydenham, and we owe a debt of gratitude to men like Creighton and Hamer for reminding us of the things which had been noted about the behaviour of "fevers" before recognition of their specificity had blinded us to their temporal and local associations with one another.

This book, packed with references as it is, is indispensable to everyone whose interest in epidemics, and especially those of influenza, extends beyond their immediate clinical manifestations.

ULTRA-VIOLET THERAPY.

Les rayons ultra-violets en thérapeutique. Second edition. Par Dr. J. SAIDMAN *et associés.* Paris: Gaston Doin. 1929. Pp. 840. Fr.100.

Dr. J. Saidman has entirely rewritten his original text-book on actinotherapy, greatly enlarged it and brought every section well up to date. The book is divided into technical, physiological (including physical and chemical) and therapeutic sections. All are well documented and clearly written and contain summaries of the most important work in every field of the subject. The vague theories and assumptions frequently found in text-books on actinotherapy are fortunately absent. The author's own experiments are quoted, especially his researches with monochromatic light at the Institute of Actinology in Paris, and recent English and German work is reviewed very fairly. The therapeutic section is distinguished by a sanity of outlook rare among enthusiastic exponents of ray therapy. There are few statements at which one could cavil. The section on pulmonary tuberculosis is perhaps the least satisfactory, since the dangers of irradiating patients with early spreading lesions is not sufficiently stressed. This is one of the few conditions with which we are acquainted in which light treatment can do serious harm and if it is used at all it should be only by those who combine sound knowledge of actinotherapeutic technique with wide clinical experience of phthisical patients. Dr. Saidman's book would gain in value if some of the sections were further condensed, for the reader with little leisure is liable to be put off by verbosity.

JOURNALS.

JOURNAL OF PATHOLOGY AND BACTERIOLOGY. Vol. XXXII., No. 3. Pp. 349–716. July, 1929.—Further observations on the nature of bacterial resistance to bacteriophage, by F. M. Burnet (Melbourne). Bacteriophage resistant strains do not necessarily change their phase (smooth or rough) in becoming resistant; they may be serologically identical with the parent strain.—An investigation of the serological relationships of 26 strains of pasteurella, by J. T. Cornelius (London). The serological groups into which a majority of the strains fall show no relationship to the animals from which they were derived.—The histogeny of teratomata, by G. W. de P. Nicholson (London). A teratoma is not homologous with an embryo; it is the result of self-differentiation of totipotent cells with the coördinating influences of an individual.—The pathological action of light, by A. G. Levy (London). On the mouse's skin, the actions of visible light in mice sensitised with hæmatoporphyrin are the same as those of ultra-violet light on ordinary animals. Stasis is produced in the vessels with exudation of plasma and subsequent necrosis; there is also hypertrophy of the epidermis.—Animal strains of hæmolytic streptococci, by J. Smith (Aberdeen). Strains from cows, horses, and guinea-pigs cannot be distinguished from human strains.—Æsculin fermentation and hæmolysis by enterococci, by O. Weatherall and J. H. Dible (London). Ability to grow in bile media and ferment æsculin are useful characters.—The influence of dilution on the carcinogenic effect of tar, by I. Hieger (London). Undiluted tar was not more effective than a 10 per cent. solution in benzene; 1 per cent. was much less active than 10 per cent.—The modifying influence of dichlorethylsulphide on the induction of tumours in mice by tar, by I. Berenblum (Leeds). A trace of mustard gas prevents tar from producing tumours by its action on the skin.—The significance of coccal organisms in experimental poliomyelitis, by R. W. Fairbrother (London). The cocci found by various observers in infantile paralysis are either air contaminations of cultures or terminal invaders.—The histology of experimental poliomyelitis, by E. W. Hurst (London). The disease is an inflammation of the whole nervous system with special involvement of the anterior horn cells which are directly poisoned by the virus. Microglia plays an important part in the cellular reaction.—Red cell diameters in 100 healthy persons and in pernicious anæmia: the effect of liver treatment, by C. Price-Jones (London). The healthy mean diameter ranges from 6·7 to 7·7 μ with a mean of 7·2. An excessive variability of diameter is even more characteristic of pernicious anæmia than a high mean diameter. Liver treatment, effective in curing the anæmia, brings the red cells towards, but not always quite up to, the normal level.—A statistical study of cholelithiasis, by D. M. B. Gross (Leeds). Local disturbances of an inflammatory kind are mainly responsible for facted stones, general metabolic factors (diabetes, atheroma) for the solitary cholesterol stone.—The action of a cytotoxic antiserum on tissue cultures, by J. S. F. Niven (Glasgow). An anti-embryo serum kills normal kidney, liver, or intestine, mouse cancer and fibroblasts, macrophages, &c. When powerful, it inhibits subsequent autolysis.—The nature of the lesions in generalised vaccinia in rabbits, by J. McIntosh and R. W. Scarff (London). The yare due to the specific virus and not to the activation of a latent infection with—e.g., pasteurella.—Innervation of human cancers, by H. Oertel (Montreal). By a modified silver method the author finds appearances which he interprets as a nervous organisation forming an integral part of cancers.—The effect of inhibition of connective tissue growth by means of substances present in tissue extracts, by T. B. Heaton (Oxford). This paper receives comment on p. 342.—Intravitam and supravital staining, by D. F. Cappell (Glasgow). A comprehensive account of the dyes used and their effects; just how cells stain depends on their state of functional activity at the moment. The reticulo-endothelial apparatus is considered in detail and the author concludes that the dust cells of the lung are epithelial in origin.—Books received.—Proceedings of the Society.—The fragility test in cases of jaundice, by W. T. Hillier (Birmingham). Best applied quantitatively.—Growth and reproduction of *B. tuberculosis*, by A. D. Gardner (Oxford). Follows ordinary lines; no evidence of any complex life-cycle.

NEW WARD OF EVESHAM HOSPITAL.—A 14-bed ward for men has just been added to Evesham Hospital and named "The Burlingham Ward" in recognition of the services rendered to the institution by the family of that name during the 50 years of its existence. Mr. Charles Burlingham, who was present at the opening ceremony, became secretary when the hospital was opened.

THE LANCET.

LONDON: SATURDAY, AUGUST 17, 1929.

A YEAR'S WORK IN THE MINISTRY OF HEALTH.

THE annual report of the Ministry of Health (1928-29) contains as usual an account of activities, many of which have a distinct medical bearing, although the report of the Chief Medical Officer of the Department is published in a separate volume. The record of the Ministry was, of course, prepared before the present Government had taken office. It deals with the more important business transacted by the Department during the twelve months, but does not cover matters of routine or detail, while the reports by the general inspectors on the administration of the poor-law during the year are omitted, because these are published separately with a reprint of the section in the main Report which deals with the subject.

A policy of continuity has been recently the marked feature of the health and sanitary legislation of this country, and the fact emerges immediately from this Report. Ten years ago, during the passage through Parliament of the Ministry of Health Act, it became obvious that there should be an overhaul of the system responsible for any direct health service to the country. The Local Government Act of 1929 is directed to the provision of remedies which have been found necessary during the ten years which have elapsed since the establishment of a single department of Government responsible for the supervision of the public health—i.e., the Ministry of Health. A prominent defect in the older pattern of organisation was constituted by the special areas which fell to the control of boards of guardians, whose duties as separate and independent authorities overlapped the duties of public health authorities in many directions. As far as medicine is concerned the responsibility placed upon the guardians to supply medical and surgical relief for the destitute was in many ways a reduplication of effort and a source of endless inefficiency. Before the Ministry of Health came into existence this anomaly had been pointed out and definitely recognised by successive Governments since 1917, and at last the administrative and financial arguments for the change have prevailed—in the words of the Report "what was then desirable has since become necessary and inevitable by the narrowing of rateable resources." The National Health Insurance Act, 1928, based on the recommendations of the Majority Report of the Royal Commission, has made many improvements of detail which have necessitated a considerable number of orders and regulations. But the essential scheme remains as at first laid down, when it represented the policy of continuity by its recognition, as a State measure, of the efforts previously made by individual members of the medical profession to furnish medical attendance on a coöperative basis for those of the public whose means did not allow of their undertaking the separate responsibility of payment. How the medical efforts were exploited by lay companies is an old story, but the National Insurance Act, in its original shape, killed the gross abuses. For the most part the new provisions came into operation on Jan. 1st, 1929, and are referred to in many parts of the Report, which makes valuable reading for all who would understand the working of the Insurance Medical Service.

The extent of that Service in 1928 gives figures to be noted. In England alone 14,300 doctors were during last year in insurance practice, while medicines and appliances were being supplied as part of medical benefit at some 9000 shops of pharmaceutical chemists. As the number of insured persons entitled to medical benefit, an analysis of whose claims appears in an earlier section of the Report, was about 13,900,000, we find the old ratio of doctor to population preserved in the latest development of coöperative practice, and the large figures we are dealing with must be remembered when we come to consider the price. Medical benefit for this community cost £8,500,000, of which sum insurance doctors received nearly £6,200,000 for discharging their normal responsibilities in attending and treating insured persons; and about £1,840,000 of the balance was paid to insurance pharmaceutical chemists for the supply of drugs and appliances. The residue was expended, in sums small by comparison with the amounts already stated, in financial adjustments necessitated by the granting of medical benefit in special conditions or circumstances. For example, about £200,000 was paid to country doctors on account of mileage, a figure that will not appear in the least excessive to those who know the demands made by a practice where the activities ramify rather than concentrate. Assistance was also rendered in such matters as the maintenance of telephones, motor cars, and branch surgeries, while about £100,000 was paid to practitioners for medicines and appliances supplied by them as part of emergency treatment, for medicines administered by them personally, and for medicines dispensed by them in country districts where no pharmaceutical chemists could be reached by the patients. Further sums of about £66,000 and £15,000 were paid on account of insured persons who exercise their option to make their own arrangements for treatment. The number of these is small, a fact which suggests that the depreciating view of the panel practitioner, which not so long ago could always be expected from a certain type of critic, has found no public reflection. In which connexion we may refer to the sections in this Report dealing with the investigation on the one hand with alleged excessive prescribing, and on the other with falling away from the standard of treatment. These abuses are practically absent when the bulk of the work is considered.

THE CONCEPTION OF NEPHROSIS.

THE label "chronic parenchymatous nephritis" has long been regarded as unsatisfactory, since patients suffering from albuminuria with œdema show great variation in the clinical course of their disorder and in response to treatment. A school of observers in America and Germany, of which A. EPSTEIN, F. MUNK, F. VOLHARD, and T. FAHR are perhaps the principal exponents, have attempted to separate off a group of patients in whom vascular lesions are completely absent, and for whom the prognosis is believed to be good, provided that a high protein diet, often coupled with thyroid medication, is instituted. The term nephrosis, as distinct from nephritis, given to this syndrome has not been generally accepted by physicians and pathologists in

Great Britain, and the views of the champions of the new classification have been frequently misunderstood or imperfectly appreciated. Most of them have been inclined to regard the syndrome as a disorder of general metabolism rather than as a disease of the kidney. Certain clinical features are essential if a case is to be placed in the category of pure nephrosis, as the term is understood by those who have supported its adoption. These clinical features are: (1) A generalised œdema with an intense albuminuria. (2) A urine of good concentration, of which the daily output is inclined to be diminished, containing no blood or any abnormal elements except albumin, fatty and hyaline casts, and doubly refractile lipoid droplets. (3) Complete absence of signs of cardiovascular involvement—i.e., a normal blood pressure, absence of cardiac hypertrophy, and a normal fundus oculi, except possibly for signs of œdema. (4) A blood picture which shows no abnormality in its chemical constituents other than increase in cholesterol and in the ratio of globulin to albumin. L. Aschoff has justly emphasised the absence of evidence of vascular involvement as the essential feature of this group of patients, distinguishing them from those suffering from severe and progressive "mixed nephritis" with a bad prognosis. Epstein and others contend that cases of true nephrosis are relatively common and are so benign that the absence of data on their morbid anatomy is readily explicable. This view is challenged by many pathologists, who contend that cases of so-called nephrosis are merely cases of Bright's disease in which the glomerular lesion has been so slight as to escape observation for a time; but that if they are watched over a proper period the usual downward course of inflammatory disease of the kidney will become apparent.

This criticism is supported in a brief but admirably written review [1] by Dr. H. A. Christian. He refers to interesting experiments, still unpublished, in which the blood protein of dogs was kept low for a long time by means of venesection, anæmia being prevented by the reinjection of the washed red blood cells. These dogs were found to develop œdema and a general picture indistinguishable from that of nephrosis. He goes on to express his belief that a primary renal lesion is probably always the initial disease in cases of human nephrosis, and that it is the leakage of albumin consequent on this lesion which is responsible for the whole of the remaining picture. It is certain, as Dr. Christian points out, that autopsies on patients with a history of œdema and albuminuria showing no lesion of the renal glomeruli or, indeed, any renal disease beyond some degeneration of the tubules, are rare. When such cases are discovered the cause of death is usually a pneumococcal infection of the ascitic fluid. Summarising the investigation, Dr. Christian concludes that, after all, not much more is known to-day than was understood by the older clinicians by the terms parenchymatous nephritis, amyloid disease of the kidney, syphilis of the kidney, the lipæmia of certain cases of nephritis, and the pasty pallor, œdema, and languor of some forms of nephritis. Extensive tubular degeneration in certain types of large white kidney has been known for a long time. Older descriptions of amyloid kidney and syphilitic nephritis, allowing for differences in terminology and lack of some new laboratory methods, correspond extremely closely with those of "lipoid" nephrosis. Diminution of concentration of plasma protein was noted by Bright in 1836, as was the milkiness of the serum; he says, "if the blood is drawn it is often buffed or the serum is milky and opaque; and nice analysis will frequently detect a great deficiency of albumin." Changes in the albumin-globulin ratio have been the subject of study for many years, and opalescent serous effusions were also demonstrated long ago. Lower basal metabolism had to await clinical methods for its determination, and this, according to Christian, is about the only new feature that recent investigations have added to our knowledge of the group of patients with extensive œdema of renal origin. Many British physicians will endorse this opinion.

Those interested in this abstruse problem will welcome a new publication[2] by another American observer, H. Elwyn, whose previous book on nephritis was read with interest in this country. His new work, which is devoted almost entirely to a discussion of the mechanism of production of œdema in various conditions, appears to be largely a compilation from the German and American literature, and students of the subject will regret the entire omission of reference to the work of A. Osman, F. Widal, C. Achard, G. A. Harrison, T. Izod Bennett, and other English and French workers in this field. The book is stimulating in the emphasis which it lays on the aspect of œdema as a compensatory mechanism designed to maintain the equilibrium of the circulating and tissue fluids of the body. The author belongs to the school which regards nephrosis as a condition in which there is an initial primary renal lesion, but he differs from Christian in that he accepts the possibility of distinguishing these cases for purposes of prognosis. In the section on treatment Dr. Elwyn gives a practical account of the employment of ammonium chloride, calcium chloride, and the new mercurial substances, such as novasurol and salyrgan, without laying much emphasis on the occasional untoward effects from these substances which have been reported.

◆

THE TREATMENT OF PNEUMONIA.

Contradictory instructions on the proper way to treat pneumonia still abound in the literature. Specific treatment has certainly advanced in recent years, but though potent polyvalent serums are now available reports show their virtue to depend mainly on the type of infecting organism. In those fortunate districts where type I. is the most common infection serum treatment has given surprisingly good results when injected early and in large doses. Two years ago Prof. Ludolph Krehl spoke enthusiastically of its merits from his experience in Heidelberg at the meeting of the Deutsche Gesellschaft für Innere Medizin held at Wiesbaden in April, 1927, and reports from other European sources have confirmed his conclusions. According to many American workers specific therapy is also successful against type II. when a highly potent serum is given in large quantities early in the course of the disease.

In a controlled series of cases R. L. Cecil and W. D. Sutliff[3] found that the death-rates of infections with type I. treated with and without serum were 32 and 18 per cent. respectively; for infections with type II. the corresponding figures were 52 and 39 per cent. Unfortunately, patients infected with types III. and IV. are not helped by the serum, and since in different countries and in different epidemics the proportion of the types varies considerably serum treatment is not yet of universal application. Other forms of specific treatment are legion, which is only another way of saying that none is really specific. Optochin, introduced by **MORGENROTH** in 1911, has never been widely employed because the difference between the therapeutic and toxic doses is so very small. Vaccines are not generally popular, though **W. H. WYNN** and others have reported their successful use when given very early. To assess the value of any form of therapy is difficult in such a variable and self-limiting disease, and the practitioner must fall back, therefore, on general principles. But these are not yet really established, even in respect to important decision whether the patient is to be protected from all draughts or nursed as far as possible out of doors. The courage needed for enjoining the open-air régime in inclement weather is considerable and family doctors will be relieved to hear that the fashion is not unchallenged. There is some support in recent literature even for the practitioner who would nurse his pneumonias with closed windows. Prof. **YANDELL HENDERSON**,[4] asserts that closure of a bronchus or bronchioles is a determining factor in the development of pneumonia. He claims that the deep breathing induced by carbon dioxide has proved capable of preventing such closure and of keeping the lungs open, and that therefore inhalation of carbon dioxide not only offers prophylaxis in the early stages of pneumonic infection, but may be of therapeutic value even in advanced stages of the disease. Even more unconventional are the views recently advanced by Dr. G. G. **CORNWALL**[5] who regards "cold air treatment" as definitely dangerous. He puts the safeguarding of the patient from chills as second in importance only to the avoidance of unnecessary examinations. British physicians will endorse this piece of advice, for it is an accepted canon in most of our schools that, once a diagnosis of lobar pneumonia has been made, it is unnecessary to examine the patient's back for at least seven days. The temperature chart, the pulse, the quality of the heart sounds, and the data available by percussion over the front of the chest will be amply sufficient to tell the doctor all he needs to know. The drugs valued by Dr. **CORNWALL** are those stimulants and sedatives which are used with nice judgment in all countries by keen physicians. With some of his precepts few will agree, for Dr. **CORNWALL** aims at underfeeding (the maximum allowed is 1200 calories), and he holds moderate constipation to be not undesirable. He looks upon many of the symptoms of pneumonia as mere manifestations of ameliorative and reparative processes calling for no meddling. Views based on a considerable experience should not, however, be overlooked. Dr. **CORNWALL** supplies a review of several hundred patients in two groups. The first group were not treated strictly in accordance with his ideas and showed a mortality of 30·6 per cent.; a second similar group on whom the treatment which he calls "physiological support" was practised showed a mortality of 17·6 per cent. The only form of treatment common to all methods of treating pneumonia seems to be that enjoining rest in bed, and the only lesson emerging at present is that unless this is insisted on the prognosis is bad.

Annotations.

"Ne quid nimis."

HEALTH IN BRITISH INDUSTRIES.

YEAR by year the annual reports of the Chief Inspector of Factories recount the activities of a health service which has done and is doing an immense amount to ensure the well-being of our industrial workers. Dr. J. C. Bridge's report[1] for 1928 tells of a combination of depression in many industries with activity in such luxury trades as motor cars, tobacco, wireless, artificial silk, chocolates, and gloves. Industry continues to grow rapidly round London, attracted by a great market and port. The small workshop is rapidly disappearing before the large factory, as labour-saving devices replace manual work, and this is a change for the better when a modern machine bakery displaces an underground bakehouse, or a "ready made" factory gets rid of tailors' and dressmakers' dens. Much attention is being paid to accident prevention, particularly by safety-first methods. Over 70 per cent. of industrial accidents are unconnected with machinery, and about a quarter are due to persons either falling or being struck by falling bodies. About one accident in ten becomes septic through infection—a high proportion when all accidents do not result in wounds. An account is given of the spread of safety organisations in various industries and of the consequent reduction in accidents which fell in our engineering works from 18·0 per 100 persons in 1924 to 6·8 in 1928; apart *from humane considerations such reduction is, of* course, a sound economic proposition. The welfare order for bakehouses, which calls for the provision of wholesome drinking-water, has disclosed the absence of such water in a number of districts of twentieth century Britain. Extension of welfare departments in works, large and small, is reported, with organised supervision by doctors and others of the health of operatives. Gradually employers are perceiving that money is saved by preventing sickness. Here an important development is occurring in the elimination of silica dust, and with it silicosis, from grinding metals. The grindstone has been almost entirely superseded by the abrasive wheel, which originates far less dust and liberates little or no free silica. The new wheels work better and quicker, and even the Sheffield "little mesters," with their almost passionate devotion to their sandstones, are ceasing to demand the right to have "tuberculosis if they wanted to." Many will read with delight the historical account of the cutlery trade to which a chapter is devoted; it will often be quoted. Of particular interest is the account given of two fatal cases of "acute" silicosis, due to inhaling dust of silica with an alkali generated in making scouring powders composed of soda ash, soap powder, and ground silica. They occurred in women after two and four years' exposure respectively. Hitherto, silicosis has been regarded as a disease of *middle-aged* men who have had many years' exposure to the dangerous dust. Another pulmonary trouble has also been recognised, due to inhaling asbestos dust generated while weaving this inorganic fibre; it produces a fibrosis which tends to be fatal. Lead poisoning continues to decline; there were 1058 cases in factories in 1900, 505 in 1910, and only 230 in 1928. In addition, 87 cases occurred from painting buildings which to-day causes far more cases of lead poisoning and fatalities than any other occupation. Anthrax has diminished in the woollen trade, but infection through hides and skins has increased. Cancer of the skin, with 175 cases, remained steady and undiminished; oil contributed 105 of these cases, nearly all in mule-spinning, with the scrotum as the site affected in 60 per cent. Dermatitis claimed considerable attention, due often to substances, notably alkalis, used to clean the skin after work; they dissolve the grease which holds the superficial skin cells together, leaving the ubiquitous germ to penetrate to the relatively unprotected deeper layers. Other cases originated from oil and "suds" in engineering. A clean skin and an emollient application prevent these troubles. The general impression to be gained from reading the report is that health depends far more than is often thought upon the way life is lived, and that sickness and disease are earned by exposure to faulty environment.

THE JAW-WINKING PHENOMENON.

THERE is an anomaly, first noticed in 1883 by the late Mr. Marcus Gunn, which affects certain people, most of whom have a partial congenital ptosis, generally unilateral. It is noticed that in these people, when the mouth is opened, and especially when the lower jaw is turned to the same side as the eye with ptosis, that eye is opened; when the mouth is closed the lid falls again. A. Léri and J. Weill[1] have lately reported this anomaly in two patients—a mother and son—and this is interesting because a familial incidence has rarely been noted before. In the mother the affection was bilateral, which is also very exceptional. The son had facial asymmetry, with partial atrophy of the side affected with ptosis. A similar facial asymmetry was seen in a daughter also (third generation) but she did *not* show the jaw-winking phenomenon. As regards causation, the explanation which has obtained most acceptance is that of Mr. Bishop Harman,[2] who attributes the condition to atavism. He points out that the first gill-slit or "spiracle" of fishes, which is homologous with the human external auditory meatus, is surrounded by a deep and also by a superficial muscle. The deep muscle extends to the lower jaw which it depresses, and is homologous with the external pterygoid in man. The superficial one closes the orifice of the spiracle and also extends to the upper eye-lid which it closes. These two muscles are antagonistic. Anyone who watches fishes in an aquarium will see that when a fish opens its mouth the operculum covering its gills swings open too. In the same way when one of the subjects of this anomaly opens his mouth the orbiculus palpebrarum ceases to act, and the levator, though generally weak in these cases, has it all its own way. This is the explanation which finds favour in England, but the French authors we have mentioned are not satisfied with it, and prefer to regard the phenomenon as a "functional association" analogous to those seen in some cases of hemiplegia.

GROWTH-INHIBITING SUBSTANCES.

SUBSTANCES—or supposed substances—which encourage growth have become very familiar in recent years. The tissue-culturist adds embryo extract to get the tissues to grow in vitro, the nutritionist gives the observed rats vitamins. The assumption is made with considerable regularity that failure to grow is due to the absence of something which promotes growth rather than to the presence of something which retards or inhibits growth. The demonstration of growth-inhibiting substances in animal and vegetable tissues is therefore of rather particular interest and may have far-reaching implications. Dr. T. B. Heaton, of Oxford, showed some time since that extracts of animal organs had a thermostable property (conveniently spoken of as a substance) of selectively inhibiting the growth of fibroblasts from fowl embryos in tissue cultures; on the growth of epithelium from the skin or bowel it had no influence. He now (*Journal of Pathology and Bacteriology*, 1929, xxxii., 565) follows this idea out in greater detail. All tissue growth in vertebrates depends on the coördinated and commensurate growth of the connective tissue with its blood-vessels. A substance which obstructs the growth of fibrous tissue should therefore impede growth as a whole. He shows that from animal tissues yeast and especially malt extracts may be made which delay the metamorphosis of tadpoles and the regeneration of amputated parts in newts; given intraperitoneally to young rats they cause immediate cessation of growth which is resumed when the dosing is omitted; pregnant guinea-pigs stop increasing in weight and abort. These are the general results of extracts which are active in preventing the growth of fibroblasts in tissue cultures; extracts which are negative to this test have no effect in the whole animal. Analogous experiments with the Jensen rat sarcoma gave similar results, the tumours ceasing to grow, and in some instances being completely absorbed. Dr. Heaton's observations are not perhaps in all instances as ample as might be wished, but they seem to open the way to an interesting and important line of inquiry.

THE LESIONS OF ACUTE RHEUMATISM.

Dr. A. F. Bernard Shaw has just published some valuable histological researches on the lesions of acute rheumatism. The source of the material was a girl of 15 who died from rheumatic fever and chorea. The exhaustive pathological and histological study made of this case is recorded in minute detail with many illustrations in the current issue of the *Archives of Diseases in Children*. Dr. Bernard Shaw shows that the virus of rheumatic infection has a predilection for connective tissue. The initial lesion there is a necrosis of the collagen followed by a focal infiltration with mobile cells including lymphocytes, plasma cells, macrophages, and many polymorphonuclears. The process is well seen in the Aschoff nodes in the myocardium, but is by no means uncommon in such widely different places as the tendinous slips of muscle, aponeurotic tissues, and arterial adventitia. The lesions in the walls of the nutrient arteries of the heart valves, coupled with those primarily in the connective tissue of the valves themselves, bring about a condition of valvulitis which may exist—and on the right side of the heart probably often does exist—without actual break of endocardial continuity. Valvulitis is, of course, often a precursor of endocarditis. The liability of a purely valvular lesion to advance to endocarditis depends on the degree of circulation of the virus permitted within the valve by its intrinsic arterial tree and the amount of mechanical stress to which the valve is exposed. Anatomical research on the intrinsic vascularity of the valves and physical assessment of the stresses to which each is exposed would lead to the theoretical assumption that endocarditis would involve the valves in the following order of frequency—mitral, aortic, tricuspid, pulmonary. This is the precise order of frequency found in practice, and therefore the suggestion that endocarditis is partly due to advancing valvulitis, caused by intrinsic arterial and connective tissue lesions, and is not transmitted only through the blood, is well supported.

In addition to discussions on the mechanism of the production of rheumatic endocarditis Dr. Bernard Shaw gives full and new descriptions of the widespread local manifestations of the general rheumatic infection in the heart muscle, the brain and meninges, the serous membranes, the muscles, the visceral arteries and veins, and the lymphoid tissue. Generally speaking, the brunt of the attack is borne in the first place by the connective tissue which presents focal necrotic lesions as the primary event and secondary cellular infiltration leading to the formation of a node. As a result of his histological researches the author dissents from the view that a deposit of fibrin forms the essential basis of a node. He is careful to explain that valvulitis may exist without subsequent or associated endocarditis, and some of his descriptions of the architecture of the lesions suggest that the primary lesion of the rheumatic virus, wherever it occurs, shows a strong tendency to heal. On the other hand, in the case described, the tricuspid valve showed abundant microscopic evidence of valvulitis but none of endocarditis, and the inference is that in many cases the valves of the right side of the heart in rheumatic fever are the site of valvulitis without clinical or macroscopic evidence of frank endocarditis.

[1] Bull. de la Soc. Méd. des Hôp. de Paris, July 8th, p. 875.

[2] Trans. Ophthal. Soc., 1903, xxiii., 356.

Dr. J. Purdon Martin, in our columns last year,[1] showed in a case of chorea a sharply defined vascular lesion at the base of the brain in the body of Luys. This structure is subjacent to the thalamus and is probably in contact with both cerebellar and pyramidal fibres. In Dr. Martin's case the lesion caused an illness indistinguishable in many respect from rheumatic chorea, and he therefore indicated the body of Luys as a probable site for focal rheumatic infection in ordinary common chorea. Dr. Bernard Shaw found no adequate anatomical bases for the chorea in any part of the brain.

THE RED CELL SEDIMENTATION TEST.

THE red cell sedimentation test has found but little popularity in England and is far less generally used here than abroad. This is perhaps fortunate since our knowledge of its significance in clinical medicine is still far from complete. Nevertheless, the subject now has a large literature, and there is no doubt that the test offers us aid in diagnosis and prognosis that can no longer be ignored. The two methods employed in carrying it out are very simple, and the minimum of apparatus needed is easily available for every practitioner. Both depend upon the rate at which the red cells sink in citrated blood on standing, and they differ only in the way in which results are recorded and in minor details of technique. Numerous modifications of these methods, which are associated with the names of Fahraeus, Linzenmeier, and Westergren, have been proposed, and results are usually given either in terms of the time taken for the deposit of red cells to reach a given height, or in terms of the height reached by the column in a given interval of time.

The diversity of the standards used by different workers and the variation in method have made it difficult to compare results, and have undoubtedly been partly responsible for the disrepute in which the test is held by many. Whichever method is adopted, all are agreed that normal healthy persons show a high suspension stability of the blood, which is to say, that the separation of red cells and plasma is slow. What this depends upon is not fully understood, and probably no single physico-chemical mechanism is entirely responsible. Prof. F. Reiche[2] has lately studied the relationship of the sedimentation-rate to some of the chemical constituents present in the blood, and to some of its physical properties such as the coagulation time and bleeding time. His investigations have been performed upon over 4000 patients, and include estimations of almost all the important substances that may be quantitatively determined in the serum and in blood. He could, however, find no one factor that could be causally related to alterations in the rate of sedimentation. This did not, for instance, depend upon the number of red or white cells present, nor upon the hæmoglobin percentage, nor upon the clotting power of the blood. Nor could Reiche confirm the suggestion that the protein content of the serum was the important factor, for variations in fibrinogen and albumin-globulin ratios were present with independent variations in sinking time. The number of platelets has also been thought to affect the rate of sedimentation, as has the size of the red cells as apart from their numbers; but apparently neither is in fact causally concerned. The amounts of chloride, calcium, cholesterin, sugar, and non-protein nitrogen were found to be independent of the suspension power of the blood.

An examination so thorough should command respect, and it must be confessed that at present no one knows what are the essential changes in the blood which increase the speed of sedimentation, or what are the factors which maintain its normal suspension stability. Despite this ignorance, however, certain general conclusions may justifiably be drawn from practical experience, and they are none the less valuable for an absence of explanation of these results. Thus it may be stated that abnormally rapid sedimentation of the red cells is always associated with organic disease and excludes a purely functional disorder. This alone is a help in differential diagnosis, for example, in neurasthenia and early phthisis. The most strongly positive results (i.e., the most rapid sinking) are usually found in those conditions in which tissue destruction, autolysis, and absorption of breakdown products are occurring; and may thus to some extent separate purulent from non-purulent, and acute from chronic inflammations. Negative results are of less significance in excluding such conditions; thus a normal reaction is occasionally noted in even advanced organic disease, and may sometimes be recorded in severe pulmonary tubercle—a condition in which the test has been widely applied as an aid to prognosis. On the other hand, positive results are very seldom seen in the absence of such disorders, except in the first two to three months of pregnancy. For the diagnosis of carcinoma the test is valueless. As a guide to the existence of latent toxæmia from the presence of a septic focus, and in the exclusion of purely neurotic conditions a positive result is of considerable significance. As an index of the progress of cases of both acute and chronic infections, notably in phthisis, the gradual return to normal of the sedimentation time of the red cells is of definite value. Many exaggerated claims have been made for its specific relationship to individual diseases, but within limitations this simple test seems to have its uses.

ASSISTED ALPINE CURES.

THE Queen Alexandra Sanatorium Fund, of which the annual report for 1928–29 has just been issued, made it possible last winter for 52 men and women to make a prolonged stay at Davos, when apart from such help they would not have been able to do so. For the last four seasons the practice has been to make block grants of £2 (50 francs) a week, allowing patients to choose their own accommodation from a list of approved establishments; and this grant scheme has worked well in practice, those who have been assisted by the Fund having recognised the responsibility which such a trust implies. Only two complaints were received from the visiting physicians in Davos, and one patient who was described by her medical attendant as "a happy-go-lucky young woman" nevertheless did extremely well. The Fund which gives these grants is the product of the sale of the Queen Alexandra Sanatorium which was built in Davos for British patients of small means some years before the war. As it proved impossible to reopen the sanatorium after the war at a fee within the reach of the class of patient for whom it had been intended, the Council of the Fund was faced with the alternative of altering the whole character of the institution, or of selling the building and devoting the proceeds to helping patients of small means to get treatment in Alpine climate in some other manner. The ordinary income of the Fund is about £2000 a year and it has recently been augmented by amalgamation with the St. Moritz Aid Fund, a smaller though similar organisation with its former seat in the Engadine. Last winter the assisted patients included two medical practitioners, two dentists, six students, three nurses, and many other professional persons. The average stay was 108 days and the medical records state that the disease was arrested in 2, apparently arrested in 5, much improved in 16, improved in 18 and slightly improved in 3. Both lungs were already affected in 31 cases, and 17 of them were febrile at the commencement of treatment. It is the desire of the Council of the Fund to give priority to those whose disease is such that a winter in the Alps may ensure a cure or consolidate one already begun, and it is hoped that the medical practitioners up and down the country, on whose recommendation the grants are made, will coöperate with the Council in selecting cases at an early stage of the disease. A second line of defence consists in the fact that a certificate of medical suitability must be obtained from one of the honorary examining physicians to the Fund. A list of these physicians and application forms are issued on request by the local secretary, Mr. W. G. Lockett, the British Consulate, Davos Platz, Switzerland.

A TREATMENT CAMP FOR CHILDREN.

IN the *World's Health*, the organ of the League of Red Cross Societies, there is usually something encouraging about the work these societies are doing in so many parts of the world. From the July number we learn how concerned South African public opinion is becoming about bilharzia, which is widespread there. Adults can come into the towns for treatment, but it is difficult to get tartrate of antimony injections to the infected children on the scattered farms. To Dr. Theron, assistant medical inspector of schools in the Rustenburg district, came the idea: why not gather the children in their holidays into a treatment camp? The suggestion caught on and help came from every side. The Transvaal Province gave £100, doubled later, and the Rustenburg primary school was rearranged as a temporary hospital with seven dormitories, an injection ward, and a room for urine analyses. Patients brought their own blankets and pillows, bedsteads were borrowed locally; mattress cases were lent by the Defence Department, the straw to fill them was begged from neighbouring farmers, who further gave much of the necessary food; Rustenburg municipality presented electric light and the extra water needed; Johannesburg school clinic lent the medical equipment; the South African Medical Institute of Johannesburg provided the distilled water, and the Red Cross gave the drugs. Two nurses were engaged, and 32 teachers and senior school girls, volunteering each for four to seven days, were invaluable in keeping the children employed and amused between their injections and entertainments. The camp opened with 60 children, but some were unsuitable and some were removed by friends; nevertheless, 49 completed their course, and all but one lost their hæmaturia. The parents paid £40 towards the cost of the camp which, thanks to local generosity, closed with a balance which it is proposed to use in providing a swimming-bath for Rustenburg, to diminish infection in future. The camp is considered a great success and was visited by many medical men. Could children with this disabling disease have spent their Christmas holidays more advantageously?

ADAPTATION OF THE EYE TO DARKNESS.

THE Medical Research Council issues a report[1] summarising the literature (chiefly German) on the dark adaptation of the eye. On the whole, variations in the sensitiveness of the retina in a state of dark adaptation are remarkably constant, not only in the same, but in different persons, and these may be due to the individual state of health, as is indicated by the recent discovery of the association of night-blindness with vitamin deficiency. A great deal of experimental work has been done on various aspects of the subject, such as the latent period between stimulus and sensation (Empfindungszeit), the duration of the primary sensation (Empfindungsdauer), the duration of what is called the colourless interval, the regional variations in the sensitiveness of the dark-adapted retina, and especially the question of dark adaptation at the fovea. It is said that foveal adaptation is now established, though this is hard to prove because it is almost impossible to fix an object of threshold intensity which is small enough to affect the fovea alone. Anyhow, the adaptation is very slight and only occurs during the first few minutes. The vexed question of the presence or absence of the Purkinje phenomenon (change of relative brightness of different colours as dark adaptation increases) at the fovea is still unsettled, most investigators finding no evidence for its presence. This and other questions discussed in the report are important in their relation to the physiology of the rods and cones, the duplicity theory, and colour vision. They have also an immediately practical bearing on aviation, for in testing the visual fitness of an airman for night-flying it is desirable to determine both his absolute sensitiveness for light and his rate of recovery after the relative blinding which follows exposure to light for short periods. Finally, the report considers dark adaptation in certain pathological conditions. The theory that what vision there is in total colour blindness is due entirely to rod function is supported by the frequent presence of a central scotoma. Night-blindness is the opposite condition in which the function of the rods is supposed to be defective. It is well known that in retinitis pigmentosa dark adaptation is especially defective. It is said to be defective in glaucoma and also in true optic neuritis, but not in choked disc.

THE GENESIS OF TROPICAL NEURASTHENIA.

WHILE all students of European life in the tropics admit that neurasthenia is a common phenomenon, few of them agree about its cause. Lieut.-Colonel Berkeley Hill contributed to the Seventh Congress of The Far Eastern Association of Tropical Medicine, held in British India in 1927, the transactions of which have now reached us,[1] an able paper on Mental Hygiene of Europeans in the Tropics. Such terms as "Punjab head" "West Coast head" imply the popular recognition of the existence of a form of neurasthenia which may take various shapes. Europeans living in the tropics are prone to a neurotic syndrome, the germ of which is a state of hyperexcitation manifested in general irritability. Although hyperexcitation may appear as a symptom of any form of psychoneurosis, it is manifest most consistently in anxiety neuroses. Symptoms, apart from worry and anxious expectation, may, in both sexes, take the form of hypochondria, which may be related to sunstroke, glare, and bowel complaints. Following Freud's conception of ætiology, Col. Berkeley Hill concludes that the prime factor in this anxiety neurosis, at any rate in men, is voluntary abstinence from sexual intercourse. The typical syndrome is found to be accentuated in the European doomed to live in an out-of-the-way place. Here the absence of others of his own race and class may bring about a loss of self-respect, and some degree of alcoholism may develop. Alcohol reduces the inhibitory forces in every direction, and a loss of control over the emotions is an early symptom. Occasionally Europeans in the tropics suffer from outbursts of anger or from a brooding melancholy. The far-reaching importance of psychological studies is a subject hardly appreciated in India. Col. Berkeley Hill notes that in the civil employment of the Government of India there are at present only four Europeans and two Indians who have had any special training in psychopathology. In the great cities of Calcutta, Bombay, and Karachi there is no European or Indian neurologist or psychiatrist with European qualifications, and in the numerous schools and colleges throughout India *there is no provision for adequate instruction* in nervous and mental diseases.

APPOINTMENTS TO THE MEDICAL RESEARCH COUNCIL.

BY an Order of the Committee of Privy Council, Viscount D'Abernon and Mr. A. G. Church, M.P., have been appointed members of the Medical Research Council on the retirement of the Earl of Balfour and Sir Charles Trevelyan. Lord D'Abernon will succeed Lord Balfour as Chairman of the Council. By another Order, made after consultation with the Medical Research Council and with the President of the Royal Society, Dr. J. J. R. Macleod, Regius professor of physiology in the University of Aberdeen, and Mr. Wilfred Trotter, honorary surgeon to University College Hospital, have been appointed members of the Council in succession to Prof. E. P. Cathcart and Sir Charles Sherrington, who retire in rotation on Sept. 30th.

BRONCHIECTASIS IN CHILDHOOD.

THE clinical picture of fully developed bronchiectasis is fairly obvious but the early stages are apt to pass unrecognised, and this is the aspect of the disease which has attracted most attention of late years. In summarising the present position Dr. Edward Thorpe[1] points out that the exact ætiology of an essentially chronic disease of this kind is often hard to determine. So many serious infectious diseases of early childhood may damage the respiratory tract, and they often follow one another so surprisingly quickly that more than one may start the early changes in the bronchial walls. Most observers agree in placing broncho-pneumonia first among the forerunners, especially when it is associated with measles or whooping-cough. The cause of this is not quite clear, but in many such cases infection is kept up by an unhealthy condition of the nasopharynx which is only too common at this age, and such a sequence of events is especially prevalent among ill-nourished children who have had rickets. A vicious circle may be established so that the child is never free from recurrent respiratory diseases which have either begun in the lungs and augmented the infection in the upper air passages, or have started in the sinuses and tonsils and have increased the damage to the lining membrane of the bronchial walls. Saccular bronchiectasis, abscess formation, and empyema are but natural sequelæ of the primary infection. Prevention is therefore all-important. Adequate convalescence after broncho-pneumonia should be secured wherever possible, and the public should be made to look on measles and whooping-cough as potentially serious diseases. Early diagnosis is by no means easy on clinical grounds alone and radiological help should be invoked long before the condition has become self-evident. A positive result is, of course, evidence of disease, but negative findings should be accepted with reserve. In suspicious cases intratracheal lipiodol may be used; the technique is not difficult, the risk is negligible, and the radiogram obtained will sometimes reveal an unsuspected amount of disease. The treatment of such a case is difficult; any infective focus in the nasopharynx should be dealt with, and prolonged convalescence is needed. Of recent years collapse therapy has been tried in some of these cases with good results, despite the relative mobility of the mediastinum in children. As a rule, 12 months' treatment suffices. It is found that in advanced cases the results of inducing pneumothorax are poor, owing to the resistance to collapse offered by the hardened walls of the bronchiectatic cavities. In these circumstances Thorpe advocates repeated bronchoscopic lavage, a measure which has not yet found much favour in this country, owing to the difficulties of technique and the prolonged institutional treatment required. The established disease is a source of distress to all concerned, but could certainly be prevented as a rule by adequate convalescent treatment of its precursors, especially measles and broncho-pneumonia.

AN EPIDEMIC OF GLANDULAR FEVER.

IN 1889 Pfeiffer described a disease in children in which there was fever, generalised swelling of the lymphatic glands, and enlargement of the spleen and liver. Eighteen years later Turk found that a similar symptom-complex was associated with well-marked lymphocytosis, and in 1920 the epidemic nature of the disorder was recognised in America. In this country in 1921 Letheby Tidy and others described cases of infective mononucleosis and identified it with the glandular fever of Pfeiffer. Since then many other cases have been described, the latest contribution to the literature being an account of an epidemic in Berne last year. Dr. E. Glanzmann[1] records that there were in all some 70 cases, 45 of them being distributed among 16 families, 2 to 4 of whose members were affected. Analysis of the notes he made on these cases enables him to give a clear account of the disease. The incubation period seems to be from seven to eight days and the earliest manifestation is a swelling of the lymphatic glands. The occipital and retro-auricular glands enlarge first, and later the axillary and inguinal glands. The swellings are for the most part moderately painful and sometimes the arrangement of the swollen glands about the face has suggested mumps. The bronchial glands may also be involved in the generalised lymphadenitis and the spasmodic cough thus caused may resemble whooping-cough. Lymphocytosis being a feature of the blood picture in both mumps and pertussis, it is easy to be led astray in isolated cases of glandular fever simulating either of these disorders. In his original papers Pfeiffer described an abdominal form of glandular fever with abdominal pain and enlargement of lymph glands especially in the ileocæcal region. The presence of an enlarged spleen and other glandular swellings help to make the diagnosis clear. There was a moderate fever in most of Glanzmann's cases, lasting usually one, two, or three weeks; it was of a daily remittent type and came to an end by lysis. Relapses were not uncommon and even when the fever had gone away the glandular swellings sometimes persisted for weeks and even months. Other organs were also affected, the liver being obviously enlarged in most cases and the spleen palpable in one-third to one-half of them. Stomatitis was noted in some of the children, and it was usual to find the lymphoid tissue of the nasopharynx taking part in the generalised lymphatic enlargement. In two cases a fleeting rubelliform rash was observed, whilst conjunctivitis was another occasional manifestation. The blood picture in glandular fever is characteristic, and in the first day or first few days of the illness 80 to 90 per cent. of the white blood corpuscles are mononuclear, though sometimes a polymorphonuclear reaction occurs at first, followed later by the mononuclear picture. The cells present are divided by Glanzmann into three types: lymphoblasts, "lymphocytoid" cells like very large lymphocytes, and still larger "monocytoid" cells. Upon ætiology he has nothing fresh to say, except that the urine of a patient with nephritis complicating glandular fever had no effect when injected into a guinea-pig. For treatment he recommends quinine during the febrile stage, with application of ultra-violet light to such glands as do not settle down after the acute symptoms are over.

A MEMORIAL TO FERNAND WIDAL.

A LETTER in our correspondence columns addressed to Sir Almroth Wright contains the announcement of a movement which we hope will receive hearty support from the medical profession in this country. A group of distinguished Frenchmen, whose names will be familiar to our readers, have decided to form a committee with the object of erecting in the Faculty of Medicine in Paris and at the Hôpital Cochin a monument to the memory of the great pathologist. Already, we are informed, the movement has had international result, those responsible for it having received promises of support from other countries. The project should be received with similar sympathy in this country where many must have had personal relations with Widal, and where all pathologists are familiar with the value of his work.

RADIUM TRUST AND COMMISSION.

A MEETING of the National Radium Trust was held on August 13th under the chairmanship of Lord Parmoor. Viscount Lee of Fareham was appointed Chairman of the Radium Commission and a member of the Trust, which is now constituted as follows: Lord Parmoor, Lord President of the Council (Chairman); Mr. Arthur Greenwood, Minister of Health; Mr. William Adamson, Secretary of State for Scotland; Sir Ernest Rutherford, President of the Royal Society; Sir John Rose Bradford, F.R.S., President of the Royal College of Physicians; Lord Moynihan, President of the Royal College of Surgeons; Lord Dawson, President of the Royal Society of Medicine; Lord Mackenzie, Chairman of the Central Liaison Committee for Voluntary Hospitals in Scotland; Prof. A. H. Burgess, President of the British Medical Association; and Lord Lee of Fareham. The Trust made preliminary arrangements in connexion with the purchase of radium, with a view to placing it as soon as practicable at the disposal of the Commission.

The Radium Commission has now been set up in accordance with the provisions of the Royal Charter, and is composed as follows: Lord Lee of Fareham, appointed by the National Radium Trust; Lieut.-Colonel Smallman, Medical Officer of the Ministry of Health, appointed by the Minister of Health; Mr. H. L. F. Fraser, Assistant Secretary of the Department of Health for Scotland, appointed by the Secretary of State for Scotland; Mr. Sidney Russ, D.Sc., Professor of Physics at the Middlesex Hospital Medical School, appointed by the Medical Research Council; and Mr. G. W. C. Kaye, D.Sc., Superintendent of the Physics Department of the National Physical Laboratory, appointed by the Department of Scientific and Industrial Research. The following members of the Commission have been selected by the Trust from a panel of 12 persons nominated by the heads of the medical profession as "having special knowledge and experience of the application of radium in the treatment of the sick": Dr. J. M. W. Morison, Lecturer in Radiology in the University of Edinburgh; Mr. G. E. Gask, Professor of Surgery in the University of London at St. Bartholomew's Hospital; Mr. W. Ernest Miles, Surgeon to the Cancer Hospital, Brompton; Mr. Comyns Berkeley, Gynæcological Surgeon to the Middlesex Hospital; Dr. Carlton Oldfield, Professor of Gynæcology in the University of Leeds; and Dr. A. J. Hall, Professor of Medicine in the University of Sheffield.

WE regret to announce the death on Sunday last of Dr. William Ewart, consulting physician to St. George's Hospital, in his eighty-first year.

BICENTENARY OF EDINBURGH ROYAL INFIRMARY On August 6th, 1729, the first patient was received at the small Edinburgh hospital which has now become the Royal Infirmary. The bicentenary will be celebrated in October.

The Clinical Interpretation of Aids to Diagnosis.

A Series of Special Articles contributed by Invitation.

XL.—EXAMINATION OF THE BLOOD FOR BILE-PIGMENT.

JAUNDICE is due to the presence of bile-pigments in the body tissues, particularly the skin, the primary underlying condition being, however, an excess in the blood of bilirubin, the chief bile-pigment. The present tendency is to direct more attention to the primary or blood condition and less to the secondary factor, the tissue staining. "Overt jaundice" refers to the condition where the skin colour is visible, in contrast to "latent jaundice" in which, though there is a hyperbilirubinæmia, no skin changes can be seen. Bile-salts are normally present in the blood and if in jaundice these are normal or diminished in quantity, with a hyperbilirubinæmia, the condition is known as "dissociated jaundice."

How Bilirubin reaches the Liver.

Bilirubin is derived from hæmoglobin, the cycle probably being as follows. The hæmoglobin is first broken down into globin and hæmatin. The iron-containing part of the hæmatin is then split off as hæmosiderin and the iron-free remainder of the molecule is converted into bilirubin, either directly or through an intermediate or prebilirubin stage. This final conversion takes place in the cells of the reticulo-endothelial system of the body, which is represented in the liver by the cells of Kupffer. These latter cells line the vascular capillaries and are separated from the bile capillaries by the polygonal or special hepatic cells. As the reticulo-endothelial system is not limited to the liver, being particularly well represented in the spleen and bone-marrow, it follows that bilirubin in the liver may have been formed there (hepatogenous) or may have been brought there by way of the blood (anhepatogenous).

How Bilirubin may Leave the Liver.

From the liver three ways of escape are possible.

(*a*) All bilirubin may pass through the polygonal cells into the bile capillaries; this is the normal course.

(*b*) All may pass away by the vascular capillaries.

(*c*) Part may pass into the bile capillaries, part may leave through the blood.

During the passage through the polygonal cells a change takes place in the bilirubin, the exact nature of which is unknown, but is thought to consist in the removal of a protein radicle. On this change, van den Bergh established the test which bears his name, for he found that the reaction of the pigment to the diazo reagent—i.e., diazotised sulphanilic acid—differed according as the bilirubin had passed through the polygonal cells or not. If the bilirubin has followed the normal course—that is, through the polygonal cells into the bile capillaries—the addition of diazotised sulphanilic acid at once produces azobilirubin, which has a deep violet colour. Bilirubin which has not passed through the polygonal cells requires the addition of alcohol to form azobilirubin, the suggestion being that the alcohol first precipitates the protein radicle and is then able to take up the pigment in solution and so produce the deep violet colour.

THE VAN DEN BERGH TEST.

The full technique of the van den Bergh test is set out in text-books of biochemistry. It suffices here to say that sera or blood plasma from different types of jaundice give different colour and time reactions, which are described as being *direct* or *indirect*, according as the coupling takes place in non-alcoholic or alcoholic solutions.

While the colour, and time required, vary within small limits, according to the observer and the solutions used, the reactions in icteric serum or blood plasma before the addition of alcohol may be summarised as follows.

1. Immediate colour change, maximal in 10–30 secs., bluish violet, intensity dependent on amount of bilirubin, known as the *prompt* or *immediate direct reaction* and characteristic of jaundice due to bile passage obstruction.

2. Colour change beginning in 1 to 15 minutes, or even longer delayed, reddish at first and gradually deepening to violet, known as the *delayed direct reaction* and characteristic of jaundice due to hæmolysis.

3. Colour change at once, reddish at first, slowly or rapidly changing to blue, known as *biphasic direct reaction;* as the rate of change approaches more closely to prompt or delayed types, it is further described as *biphasic prompt direct* or *biphasic delayed direct.* This reaction is the one most frequently present in toxic infective jaundice.

Van den Bergh reaction.	Type.	Pathological change.		Bilirubinæmia.	Jaundice.	Bile-salts.	Resistance to saline hæmolysis.
		Nature.	Site.				
Direct prompt.	Obstructive.	Obstruction.	Biliary passages.	Large.	Marked.	Increased.	Increased.
Biphasic.	Toxic infective.	Damage.	Liver cells.	Varies.	Varies.	Dissociated jaundice.	—
Direct delayed or indirect.	Hæmolytic.	Increased blood cell destruction.	Extra-hepatic.	,,	Inconstant and varies.	,,	Decreased.

The table summarises within very wide limits some of the points of difference of the various uncomplicated types of jaundice In reading it the tendency of types to merge must be remembered.

Quantitative Estimations.

In alcoholic solutions all icteric sera give an immediate reaction known as the *indirect reaction*, and this can be used quantitatively by comparison with known standards, whereas the direct reactions are only qualitative. For purposes of estimation one part of bilirubin in 200,000 is known as a "unit" of bilirubin or a "van den Bergh unit." Normally the amount of bilirubin in the blood, known as the functional bilirubinæmia, varies from 0·2 to 0·6 units (1–1,000,000 to 1–350,000); when obstruction is present bilirubinuria occurs with a concentration of 1–50,000 (approx.); jaundice is said to be present with a concentration of 1–80,000 (approx.), though it may not be visible; in long-standing cases a concentration as high as 1–4000 has been reached.

A New Conception of Jaundice.

As a result of the van den Bergh reaction a new conception of jaundice has been formulated, according to which jaundice may arise in several ways.

1. When the bile-pigment is normally formed, but obstructed after reaching the bile capillaries and then reabsorbed into the blood.

2. When the polygonal cells of the liver cannot deal with the amount of bile-pigment which reaches them. This may be due to (*a*) such damage or functional derangement of the polygonal cells that the pigment passes direct to the general circulation by the hepatic veins; or (*b*) too much bile-pigment reaching normal polygonal cells so that some passes through into the bile capillaries in the normal way, but the excess passes by the hepatic veins into the general circulation.

3. When there is present both damage to the polygonal cells and obstruction in the bile passages. In this case some bile-pigment may get through the partially damaged cells to be obstructed in the bile passages and reabsorbed, while some passes directly to the general circulation by way of the hepatic veins.

It is on these theoretical considerations that J. W. McNee has founded his classification of jaundice :—

1. Obstructive
2. Toxic infective } hepatic jaundice.
3. Hæmolytic jaundice.

While all cases of jaundice can be covered by these three divisions, it does not follow that all clinical varieties can be confined within one division. In a complex organ like the liver one pathological state passes gradually into another, and as McNee puts it, "Toxic jaundice, with varying degrees of damage to the liver cells, may be combined with hæmolysis, and in its later stages with obstruction of the biliary passages as well."[1]

IMMEDIATE DIRECT REACTION.

When the van den Bergh reaction is *immediate direct* the diagnosis is probably obstructive hepatic jaundice at an early stage of its development. Here the bile is normally formed but there is obstruction in the bile passages and the bile is reabsorbed into the blood. A biphasic reaction would not exclude this type of jaundice, for at a later stage complete obstruction may produce liver damage. When this has occurred, however, the jaundice properly belongs to the toxic infective group.

The causes of obstruction are many and varied. They can be classified as :—

(*a*) Obstruction within the lumen of the bile passages —e.g., gall-stones or parasites.

(*b*) Obstruction due to changes in the walls of the larger bile passages—e.g., catarrhal or common hepatic infective jaundice, infective and suppurative forms of cholangitis. (In catarrhal jaundice the van den Bergh reaction may be of the obstructive type at first, but it is extremely variable and in later stages is biphasic and indicative of the toxic infective type. The same applies, and in greater degree, to the various forms of cholangitis.)

(*c*) Obstruction due to pressure on the bile passages from without—e.g., hepatic cirrhosis (jaundice often latent); intrahepatic tumours; malignant glands in the portal fissure, carcinoma of pancreas or stomach; chronic pancreatitis.

Many other possible causes have been mentioned, but a stone in the common duct and tumours of liver and pancreas are probably the most common causes of obstructive jaundice. Other blood characteristics are excessive bile-salts in the early stages, though their production soon ceases; the bile-pigment, however, continues to be formed, so that in the simple obstructive cases there is a definite relationship between the completeness and duration of the obstruction and the degree of jaundice. There is a slight hypercholesterolæmia and the coagulation time is prolonged. The resistance to hæmolysis by hypotonic salt solution is increased and the corpuscles are increased in size, the reverse being the case in hæmolytic icterus. Advanced obstructive jaundice shows a leucocytosis, but not the mild cases unless inflammation or *suppuration is also present.*

BIPHASIC REACTION.

A biphasic reaction is suggestive of toxic or infective jaundice. In this group, as the name implies, we are dealing with some infection or intoxication which produces a degeneration of the liver cells and later probably a cholangitis. The van den Bergh reaction is generally biphasic but may vary from time to time as the condition progresses or as the amount of secondary biliary obstruction fluctuates. Among the conditions classified in the toxic or infective group are catarrhal jaundice, spirochætosis hæmorrhagica, acute necrosis of the liver. Various protozoal and bacterial infections may give rise to this type of jaundice, also chronic cardiac disease with back pressure, and some forms of poisoning or toxæmias, such as those associated with pregnancy. Considering the group as a whole there is less bilirubinæmia than in the obstructive group, and grave liver derangement may coexist with slight jaundice. Bile-salts may be absent from the blood even when jaundice is well marked (the so-called "dissociated jaundice"). Some bile generally reaches the bowel so that the stools are not clay-coloured, but they are often offensive owing to the absence of bile-acids.

---

[1] Rolleston and McNee: Diseases of the Liver, Gall-bladder, and Bile-ducts, London, 1929.

Points in the differential diagnosis of the various members of the group are as follows:—

In *Spirochætosis hæmorrhagica* (Weil's disease) there is a polymorphonuclear leucocytosis and later a secondary anæmia; in the early stages the *Leptospira icterohæmorrhagiæ* is present in the blood and later in the urine. In *acute yellow atrophy* the blood shows delayed coagulation, a moderate leucocytosis, and diminished cholesterol; the colon bacillus is sometimes present on culture. In *catarrhal jaundice* there is a secondary anæmia with leucopenia.

REACTION OF DELAYED TYPE.

When the van den Bergh reaction is of the delayed type, or gives no direct response at all, hæmolytic jaundice may be suspected. In this type of icterus the underlying factor is an excessive bilirubinæmia due to the production of more bile-pigment than even a healthy liver can deal with. This excess may be due to: (1) increased destructive agents; or (2) increased fragility of the blood cells.

When it is due to increased destructive agents (so-called secondary cases) the cause of the hæmolysis is more or less known. Blood transfusion with unsuitable donors, streptococcal infections, parasitic infections, poisoning from snake-bite, Addison's anæmia, or blackwater fever may induce hæmolytic jaundice of this kind. On the other hand, the hæmolysis may be due to increased fragility of the blood cells—for example in congenital, hereditary, or familial acholuric jaundice or in acquired acholuric jaundice (often after some infection). How far these two types of acholuric jaundice are separate entities is a debatable point.

Taking the group as a whole hæmolytic jaundice is a "dissociated jaundice," since the bile-salts are not retained in the blood. The tissue reaction may be slight compared with the amount of bilirubinæmia and, finally, the kidney threshold for bilirubin is decidedly higher than in the obstructive type. The icterus is inconstant and varies greatly, there is some degree of secondary anæmia, and the spleen is often enlarged. With regard to special members of the group, the blood picture is that of the primary disease in those of the secondary type. In acholuric jaundice the presence of reticulated red cells (only shown by vital staining) and the undue fragility of the red corpuscles is a constant feature. If normal red corpuscles are placed in varying dilutions of hypotonic saline, hæmolysis starts at about 0·50 per cent., is well marked at 0·45 per cent., and is, as a rule, completed at 0·35 per cent. In acholuric jaundice hæmolysis starts at about 0·70 per cent. and is often completed at 0·50 per cent.

FOUCHET'S TEST AND THE ICTERIC INDEX.

The van den Bergh reaction is quantitative and qualitative. There are two other quantitative tests for bilirubinæmia—Fouchet's test and the icteric index. The former, which is largely used in France, is not so sensitive as the van den Bergh test, but is said to give a positive result in a dilution of 1–60,000 of bilirubin. In estimating the icteric index the yellowness of the serum is compared against a known standard. The normal lies between 4–6, overt jaundice is present when the index is above 15, and latent jaundice lies between 6–16. The index is raised in uncomplicated cases of hæmolytic anæmias, in chronic sepsis especially of the biliary tract, in pneumonia, and in cardiac insufficiency. A source of error is coloration due to pigments from ingested food so that the blood should be taken from the fasting patient. Since the test can be done with the blood available from a finger prick it has certain advantages, but if any doubt exists it should be checked by the van den Bergh reaction. In a case of overt jaundice it presents an easy method of noting the progress of the bilirubinæmia.

CONCLUSION.

In addition to their value as a diagnostic agent in jaundice, the van den Bergh reaction and to a less extent the icteric index are of use in checking treatment and in prognosis. A routine examination of the blood shows the progress of the bilirubinæmia before any change is visible in the skin. The detection of a latent jaundice may be of great value, particularly in cases undergoing treatment with arsenical compounds.

RADIOLOGICAL TREATMENT OF CANCER.

RECOMMENDATIONS ON STANDARDS AND TECHNIQUE.

A FORTNIGHT ago[1] we drew attention to the recent work of the Cancer Commission of the League of Nations in connexion with the radiological treatment of malignant disease. The Commission felt that the great publicity now being given to radiotherapy, and the elaborate and costly apparatus and arrangements required for its practice, demanded a collection of international experience. They therefore appointed a subcommission consisting of Prof. C. Regaud (Chairman), Sir George Buchanan (Chairman of the Cancer Commission, ex-officio), Mr. Comyns Berkeley (London), Prof. A. Döderlein (Munich), Dr. J. Heyman (Stockholm), Prof. W. Lahm (Chemnitz), Prof. E. Pestalozza (Rome), and Prof. A. H. M. J. van Rooy (Amsterdam). Dr. Janet Lane-Claypon was appointed special investigator, and the subcommission was charged to report upon: (1) the radiotherapeutic methods which can be regarded as of established utility for the treatment of cancer of the cervix; (2) the possibility of presenting radiotherapeutic results statistically; and (3) the principles which should be accepted to ensure most effective organisation of radiotherapeutic treatment of uterine cancer and to avoid dangers as far as possible.

The Commission met three times during the year 1928-29, and appointed Prof. F. Voltz, Dr. A. Lacassagne, and Dr. Heyman, together with Dr. E. Tomanek (the Secretary of the Commission), to prepare special reports from the clinics of Munich, Paris, and Stockholm. These reports are published in the volume just issued.[2] As we have already noted, the work entrusted to Dr. Lane-Claypon was a statistical study of the results supplied by the three institutes. She spent much time and labour on an attempt to draw conclusions as to the relative value of different methods of treatment, but she found that the three clinics had not followed the same principles in classifying the different forms of utero-vaginal carcinoma, that they had not adopted the same grouping of different stages, and that the methods in use over a number of years had varied even in the same clinic.

---

[1] THE LANCET, August 3rd, p. 235.

[2] League of Nation's Publications: Health. 1929. III., 5. Pp. 82. Obtainable from Constable and Co., Ltd., London, W.C.

The Commission concluded that no fair correlation of the work of different clinics could be made with the material at present available; its recommendations are designed to ensure a happier result from future inquiries.

Rules for Obtaining Full and Comparable Statistics.

The three institutions submitting reports have agreed to accept a model case-record drawn up by the subcommission (see Figure) and to follow certain rules laid down. The Commission hopes that all radiological institutes will adopt this scheme.

Only cases microscopically diagnosed should be included; adenoma, pre-cancerous conditions, sarcoma, and other non-carcinomatous growths must be differentiated. Growths are to be divided into vaginal, cervical, and corporal as before. A growth should be classed as vaginal only when the cervix is intact, and there is no ground for supposing that it is anything but a primary growth in the vagina. Cases in which a small cervical lesion has disappeared under radiological treatment, while the main part of the tumour is still in the vagina, are to be classed as vaginal. When the cervix has not been examined at the beginning of treatment, diagnosis must be postponed until the situation has been clarified. If, even after radiological treatment, the cervix cannot be examined, the growth should be classed as vaginal if rectal examination shows the cervix and parametria to be clinically free from growth. Carcinoma of the body should be diagnosed only when the cervix is healthy. In the absence of sufficient indications for determining the point of origin, the microscopical report should provide a reasonably safe basis for diagnosis—e.g., pure squamous-celled carcinoma and adeno-carcinoma with mucous secretion are both cervical types of growth. If the cavity of the uterus is enlarged and clinical examination does not differentiate between endocervical carcinoma extending to the body and carcinoma of the body extending to the cervix, the distinction is of theoretical rather than of practical importance. These growths behave like, and should be classed as, growths of the body unless the microscopical picture forbids.

Model case-record card. The front of the card also leaves room for details of accessory treatment, whilst the back is devoted to results. The elaborate particulars of treatment to be entered under the various headings are set out at length in the report.

The stages of anatomical extent are given as follows.

Stage I.—The growth is strictly limited to the cervix uteri. Uterus mobile.

Stage II.—Lesion spreading into one or more fornices with or without infiltration of the parametrium adjacent to the uterus, the uterus retaining some degree of mobility.

Stage III.—(*a*) Nodular infiltration of the parametria on one or both sides extending to the wall of the pelvis, with limited mobility of the uterus or massive infiltration of one parametrium with fixation of the uterus. (*b*) More or less superficial infiltration of a large part of the vagina, with a mobile uterus. (*c*) Isolated metastases in the pelvic glands, with a relatively small primary growth. (*d*) Isolated metastases in the lower part of the vagina. Generally speaking, all cases not falling into Stages II. or IV. to be placed under Stage III.

Stage IV.—(*a*) Cases with massive infiltration of both parametria extending to the walls of the pelvis. (*b*) Carcinoma involving the bladder or rectum. (*c*) The whole vagina infiltrated (rigid vaginal passage), *or one vaginal wall infiltrated along its whole length with fixation of* the primary growth. (*d*) Remote metastases.

For statistical purposes, only cases of cervical carcinoma which have been under observation for at least five years should be included, grouped into (*a*) those treated in the first instance by radiotherapy; (*b*) post-operative recurrences and cases treated by palliative operation; (*c*) those treated by post-operative prophylactic irradiation. Records should also include the total number of patients seeking treatment for cervical carcinoma and the numbers accepted and rejected together with the reasons for rejection, specifying whether it was the general condition or complications, lack of accommodation, refusal to undergo treatment or failure to keep appointment, radiological treatment elsewhere, or any other reason. Clinical diagnosis should be confirmed microscopically, and the number of cases in each of the different stages should be stated among all those accepted for treatment and among those with no signs of the disease five or more years after treatment. Recurrences after total hysterectomy should be classified as local recurrence in the scar, or as distant recurrence. In setting out the results of the treatment, no deduction should be made for patients whose treatment was interrupted or who died or were lost sight of during the first five years after treatment. Figures should be based on the number of cases treated and not on the number examined.

Detailed instructions are given in the report for supplying data relating to technique.

Reports from Stockholm, Paris, and Munich.

Dr. J. Heyman provides a report of the work carried out by Prof. G. Forssell at Radiumhemmet, which was founded in 1910. Forssell gradually arrived at a technique which had as its main principles a small number (three at most) of applications of relatively large quantities (100–120 mg. of radium element) with heavy filtration (equivalent to 3 mm. of lead), concentrated into a period of three or four weeks with an interval of one week between the first two and of three weeks between the last two treatments, and a total irradiation of about sixty hours. In 1920 leading gynæcologists of Sweden agreed to cease operating for cancer of the cervix in order to give radiotherapy a chance to show its worth. So successful was it that few radical operations for cervical carcinoma have been performed since. In the last ten years the number of operable cases treated by radium has increased tenfold, while the number of inoperable cases so treated has trebled. Dr. Heyman describes in detail the organisation of the clinic, the applicators and the various types of technique. His five-year result in all cases of cancer of the cervix treated between 1914 and 1923 is 23·1 per cent. alive and free from recurrence. Of the operable cases treated during the same period 43·6 per cent. are alive and well, and of inoperable and border-line cases 16 per cent.

Since 1913 no case of uterine cancer has been treated by operation at the University Gynæcological Clinic at Munich. The principle of radiological treatment involves several treatments at intervals of eight weeks. On the first day after admission, deep therapy is applied to the pituitary body with the object of sensitising the cancer. On the following day, X rays are applied back and front over a large field. If the general condition of the patient demands a split dose, the irradiation is given on two or three consecutive days. The tubes used are run at 200 kilovolts and 2·5 milliampères, and the rays are filtered through 1 mm. of copper. The pituitary areas receive 30 per cent., and the uterine areas 90 per cent., of an erythema dose. On the day after X ray treatment the patient rests; the next day is occupied by any necessary surgical measures—biopsy, fulguration, cauterisation, or cataphoresis—and after another day's rest radio-active substances are applied. The primary filtration is 0·2 mm. of silver; 1 mm. of brass and a layer of thin rubber are added for radio-active substances placed within the womb. The maximum dose is 1400 mg.-hours. Usually 55 mg. radium element are left in for 24 hours. After another day's rest, the patient leaves hospital on the ninth day. Eight weeks later the patient returns for six days, and the treatment is repeated with the omission of the pituitary irradiation. If a third treatment is considered necessary, the second scheme is repeated eight weeks later. Of the operable cases treated between 1913 and 1923, 50·2 per cent. were cured; of the border-line cases, 28·3 per cent.; and of the inoperable cases, 10·7 per cent. The crude survival rate for the whole series is 18·2 per cent. Analysis of the figures shows that the results are much better if X rays are combined with radio-active substances; that the best results are obtained after the thirty-fifth year of life; that the end of the third year after treatment shows well enough what the later results are going to be; and that the poorer classes of the community have a much lower survival rate than the well-to-do. Prof. Voltz lays stress on the importance of systematic treatment and the accurate completion of the plan when once determined. He also sees the possibility of improved results from better after-care of poor patients. He describes the organisation of his clinic, and illustrates his apparatus with some excellent photographs.

Radio-active bodies were first used in Paris for cancer in 1910. Dr. Lacassagne surveys the history of the work, the present organisation of the service, and the conditions which affect the efficacy of radiotherapy. Radium is applied within the cavity and also at a distance, and most cases are treated by the combined method. For intra-uterine application, three tubes are placed end to end in a rubber sheath 1·5 mm. thick; the primary filtration is 1 mm. of iridio-platinum. Two of the tubes contain 13·33 mg. and one contains 6·66 mg. Three similar tubes are placed in the vagina, the 13·33 mg. tubes lying in the lateral fornices. The primary filtration is 1·5 mm. of platinum and the secondary is a cork holder 0·5 cm. thick. Distant radium is administered by means of a cup-shaped container made of lead 6 mm. thick containing 4 g. of radium, placed at a distance of 10 cm. and irradiating through a rectangular aperture of 150 sq. cm. The dose is a 10-hour exposure through 1 mm. of platinum, and is divided over 25 days and eight fields. It usually causes dry desquamation and marked pigmentation.

X rays are also given in intensive doses twice daily for an hour or more for 15 to 25 days. The total distance is 60 to 80 cm., the tension 180 to 200, the intensity 4 to 5 ma., and the filter 1 to 2 mm. of zinc or copper. The percentage of cures between 1919 and 1923 is 20.

The Conditions for an Effective Campaign against Cancer of the Uterus.

Prof. Regaud supplies a chapter summarising the general conclusions of the subcommission, which are believed to be truly international in their application. He stresses the supreme importance of early diagnosis, and the value of public propaganda and of periodical examination of all women who have borne a child. A centre for gynæcological diagnosis need not necessarily be directed by specialists, but it must have, or be in touch with, a department of micropathology. Experience shows that a few good laboratories are better than a large number, scattered in small towns; liaison can be satisfactorily established through the post. While consultation centres for diagnosis should be numerous and easily accessible, treatment centres should be few, and it is important that the diagnostic clinic should not become a radium institute.

"For those who have not reflected on the amount of knowledge and experience lying at the back of apparently simple actions," writes Prof. Regaud, "the manipulation of radium and rontgenotherapy seems so easy that many are tempted to adopt the treatment in their own practice without undergoing the necessary preparation for the work. Individual surgeons and gynæcologists, in private practice or running small clinics, constitute themselves the radiotherapeutists of their patients. Some radiologists, more familiar with radiodiagnosis than with cancer and gynæcology, undertake the treatment of uterine cancer."

He points out that no such assumption of operative ability could be made, and foreshadows the great difficulty in proper organisation of radiation treatment which will be caused by this attitude on the part of practitioners, and the public assent given to it through ignorance. He deprecates the supply of radium—which may be insufficient in quantity or contained in out-of-date apparatus—to small local hospitals, and the hire of radium by practitioners who order it as they would a drug. The abuse of X rays is, he thinks, less harmful than the abuse of radium.

"The mischief of bad rontgenotherapy lies not so much in that it deprives patients of treatment by other methods which might cure them, as that it deprives internal radium therapy of a valuable ally, which might help to increase considerably the number of patients capable of being cured."

The subcommission recommend the concentration of treatment of cancer of the uterus in a small number of perfectly equipped institutions. It desires to draw the attention of the various authorities concerned to the disastrous results which might arise either by encouraging, or by allowing without any control, the widespread use of radiotherapy for the treatment of cancer, notably cancer of the uterus, in the hospitals or institutions which are maintained by public authorities. Without being able to express a dogmatic opinion on methods of technique, about which specialists still disagree, the Commission wishes to warn medical men and the public against the use of insufficient quantities of radium—the few needles or one or two tubes with which practitioners and small clinics sometimes attempt to treat patients. It insists on the difficulty of providing an effective and harmless deep pelvic irradiation, on the necessary strength of machines and tubes, on the great labour necessary for efficacious treatment, and on the obligation resting on doctors not to allow radiotherapy to pass into unskilled hands.

MEDICINE AND THE LAW.

Dangerous Drugs Regulations: Keeping a Register.

THERE still seems to be some misunderstanding about the obligation to keep a register under the Dangerous Drugs Regulations. A medical practitioner was fined 10 guineas including costs at Manchester on August 7th for failing to keep a register and to enter therein the true particulars of the drugs named in the summons. The defendant had undertaken work at Hull last April, as locum tenent during the absence of a local practitioner on holiday. He had ordered tincture of opium and liquid morphine hydrochloride from a local chemist, but made no entry of these purchases though there were 15 entries in the day-book of drugs used. On the defendant's behalf there was produced in court a small handbook containing particulars of the purchases, and it was apparently common ground that, if these particulars had been entered in the dangerous drugs register, they would have complied with the regulations. Defendant said he considered he had no other book to keep because he had never dispensed drugs above the strength laid down by the regulations. The Hull stipendiary magistrate, in imposing a fine as already stated, held that the statute required the keeping of a proper record of where the drugs came from and what became of them.

Section 7 of the Act of 1920 expressly authorises the Home Office to make regulations requiring persons engaged in the manufacture, sale, or distribution of drugs within Part III. of the Act to keep such books as may be prescribed; it would thus hardly be possible to argue that the regulations were ultra vires. The consolidated regulations, issued afresh last December, contain specific provisions as to the form of the register and the time and method of making entries therein; but there is a special exemption for any duly qualified medical practitioner who "enters in a day-book particulars of every drug or preparation supplied by him to any person, together with the name and address of that person and the date of supply, and enters in a separate book kept for the purpose of this regulation a proper reference to each entry in the day-book which relates to the supply of any drug or preparation."

In the recent proceedings at Hull, instituted by the Director of Public Prosecutions, the prosecuting solicitor mentioned that when the resident practitioner returned from his holiday he found nothing remaining in the surgery of various quantities of tincture of opium, liquid morphine, and morphine tablets which had been left there at his departure. From the necessarily abbreviated report of the case it is not clear how far this statement was relevant to the summons, but apparently there was no sufficient record of the disposal of these drugs. Practitioners, when making holiday arrangements with a locum tenent, will bear in mind the desirability of taking steps to avoid the chance of misunderstanding in such circumstances.

Falsification of Prescription by Addict.

The Dangerous Drugs Acts and similar legislation cannot prevent every danger of abuse of drugs. Poisonous disinfectants are readily purchasable by would-be suicides. Last month a mother (found by the jury to have been "guilty but insane") poisoned her child by administering two dessertspoonfuls of a liquid consisting of a pint of water in which she had dissolved 300 aspirin tablets. Nevertheless, the Acts, so far as any legislation can, make things more difficult for those who would make improper use of drugs, and especially for the drug addict. In another case last month the evidence disclosed a long story of attempts to obtain drugs illegally; the case ended in prosecution and imprisonment, and the defendant will have a chance in prison of curing himself of drug addiction against which, it was said, he had made a good fight. The accused man, Leslie James Stonelake, aged 34, charged at Marlborough-street on July 14th, was stated to have been in April last an assistant engineer in a ship sailing from Australia to London and to have been treated on the voyage by the ship's doctor for asthma and drug addiction. The doctor succeeded in reducing Stonelake's drug consumption from 15 grains to half a grain a day. When the ship reached London at the end of the month, the doctor gave him a prescription for one tablet of hyoscine and one tablet of morphine sulphate; the total amount in the tablets was half a grain, and the prescription was marked "Not to be repeated." Stonelake presented the prescription to a Piccadilly chemist on May 9th, having altered "¼" into "½" and "1" in each case into "12." The chemist, believing the prescription to be genuine, furnished the drugs. On April 27th, 28th, and 29th he had presented prescriptions from another doctor who authorised a "repeat" and had obtained morphine thereby. On April 30th he presented a further prescription from yet another doctor and obtained 24 tablets; on May 11th he presented yet another prescription from a fresh doctor and obtained 24 tablets again. These large supplies at last aroused the chemist's suspicions, and the prosecution followed. A member of the staff of the Marylebone Hospital said the accused came to him from a nursing home which he had left for want of money to continue the treatment there; he was treated with daily reduced doses till June 10th when he ceased to take morphine; he had taken none since. The witness said the defendant had put up a good fight against the drug and could be cured; he had little of the physical or mental degeneration which usually accompanied such cases. The magistrate, Mr. Mead, sentenced the accused to three months' imprisonment in the second division on the charge of being in unauthorised possession of 12 grains of morphine sulphate (under the altered prescription) and dismissed the charge of procuring the drug on May 9th. The accused had, of course, committed several offences; there was also the element of forgery, but with this the magistrate could not himself deal; it was clearly unnecessary to commit the man for trial. The case shows the administration of the law in the best interests of the accused.

Medical Titles.

So far as it is a personal matter, Lieut.-Colonel Kynaston is to be congratulated on the success of his recent appeal to the London Sessions. The upshot of the decision is that he has committed no offence against the Medical Act in continuing to use the title, "M.R.C.S. (Eng.)," though the Royal College has taken that title away. Apart from the personal aspect appointment, radiological treatment elsewhere, or any other reason. Clinical diagnosis should be confirmed microscopically, and the number of cases in each of the different stages should be stated among all those accepted for treatment and among those with no signs of the disease five or more years after treatment. Recurrences after total hysterectomy should be classified as local recurrence in the scar, or as distant recurrence. In setting out the results of the treatment, no deduction should be made for patients whose treatment was interrupted or who died or were lost sight of during the first five years after treatment. Figures should be based on the number of cases treated and not on the number examined.

Detailed instructions are given in the report for supplying data relating to technique.

Reports from Stockholm, Paris, and Munich.

Dr. J. Heyman provides a report of the work carried out by Prof. G. Forssell at Radiumhemmet, which was founded in 1910. Forssell gradually arrived at a technique which had as its main principles a small number (three at most) of applications of relatively large quantities (100–120 mg. of radium element) with heavy filtration (equivalent to 3 mm. of lead). concentrated into a period of three or four weeks with an interval of one week between the first two and of three weeks between the last two treatments, and a total irradiation of about sixty hours. In 1920 leading gynæcologists of Sweden agreed to cease operating for cancer of the cervix in order to give radiotherapy a chance to show its worth. So successful was it that few radical operations for cervical carcinoma have been performed since. In the last ten years the number of operable cases treated by radium has increased tenfold, while the number of inoperable cases so treated has trebled. Dr. Heyman describes in detail the organisation of the clinic, the applicators and the various types of technique. His five-year result in all cases of cancer of the cervix treated between 1914 and 1923 is 23·1 per cent. alive and free from recurrence. Of the operable cases treated during the same period 43·6 per cent. are alive and well, and of inoperable and border-line cases 16 per cent.

Since 1913 no case of uterine cancer has been treated by operation at the University Gynæcological Clinic at Munich. The principle of radiological treatment involves several treatments at intervals of eight weeks. On the first day after admission, deep therapy is applied to the pituitary body with the object of sensitising the cancer. On the following day, X rays are applied back and front over a large field. If the general condition of the patient demands a split dose, the irradiation is given on two or three consecutive days. The tubes used are run at 200 kilovolts and 2·5 milliampères, and the rays are filtered through 1 mm. of copper. The pituitary areas receive 30 per cent., and the uterine areas 90 per cent., of an erythema dose. On the day after X ray treatment the patient rests; the next day is occupied by any necessary surgical measures—biopsy, fulguration, cauterisation, or cataphoresis—and after another day's rest radio-active substances are applied. The primary filtration is 0·2 mm. of silver; 1 mm. of brass and a layer of thin rubber are added for radio-active substances placed within the womb. The maximum dose is 1400 mg.-hours. Usually 55 mg. radium element are left in for 24 hours. After another day's rest, the patient leaves hospital on the ninth day. Eight weeks later the patient returns for six days, and the treatment is repeated with the omission of the pituitary irradiation. If a third treatment is considered necessary, the second scheme is repeated eight weeks later. Of the operable cases treated between 1913 and 1923, 50·2 per cent. were cured; of the border-line cases, 28·3 per cent.; and of the inoperable cases, 10·7 per cent. The crude survival rate for the whole series is 18·2 per cent. Analysis of the figures shows that the results are much better if X rays are combined with radio-active substances; that the best results are obtained after the thirty-fifth year of life; that the end of the third year after treatment shows well enough what the later results are going to be; and that the poorer classes of the community have a much lower survival rate than the well-to-do. Prof. Voltz lays stress on the importance of systematic treatment and the accurate completion of the plan when once determined. He also sees the possibility of improved results from better after-care of poor patients. He describes the organisation of his clinic, and illustrates his apparatus with some excellent photographs.

Radio-active bodies were first used in Paris for cancer in 1919. Dr. Lacassagne surveys the history of the work, the present organisation of the service, and the conditions which affect the efficacy of radiotherapy. Radium is applied within the cavity and also at a distance, and most cases are treated by the combined method. For intra-uterine application, three tubes are placed end to end in a rubber sheath 1·5 mm. thick; the primary filtration is 1 mm. of iridio-platinum. Two of the tubes contain 13·33 mg. and one contains 6·66 mg. Three similar tubes are placed in the vagina, the 13·33 mg. tubes lying in the lateral fornices. The primary filtration is 1·5 mm. of platinum and the secondary is a cork holder 0·5 cm. thick. Distant radium is administered by means of a cup-shaped container made of lead 6 mm. thick containing 4 g. of radium, placed at a distance of 10 cm. and irradiating through a rectangular aperture of 150 sq. cm. The dose is a 10-hour exposure through 1 mm. of platinum, and is divided over 25 days and eight fields. It usually causes dry desquamation and marked pigmentation.

X rays are also given in intensive doses twice daily for an hour or more for 15 to 25 days. The total distance is 60 to 80 cm., the tension 180 to 200, the intensity 4 to 5 ma., and the filter 1 to 2 mm. of zinc or copper. The percentage of cures between 1919 and 1923 is 20.

The Conditions for an Effective Campaign against Cancer of the Uterus.

Prof. Regaud supplies a chapter summarising the general conclusions of the subcommission, which are believed to be truly international in their application. He stresses the supreme importance of early diagnosis, and the value of public propaganda and of periodical examination of all women who have borne a child. A centre for gynæcological diagnosis need not necessarily be directed by specialists, but it must have, or be in touch with, a department of micropathology. Experience shows that a few good laboratories are better than a large number, scattered in small towns; liaison can be satisfactorily established through the post. While consultation centres for diagnosis should be numerous and easily accessible, treatment centres should be few, and it is important that the diagnostic clinic should not become a radium institute.

> "For those who have not reflected on the amount of knowledge and experience lying at the back of apparently simple actions," writes Prof. Regaud, "the manipulation of radium and rontgenotherapy seems so easy that many are tempted to adopt the treatment in their own practice without undergoing the necessary preparation for the work. Individual surgeons and gynæcologists, in private practice or running small clinics, constitute themselves the radiotherapeutists of their patients. Some radiologists, more familiar with radiodiagnosis than with cancer and gynæcology, undertake the treatment of uterine cancer."

He points out that no such assumption of operative ability could be made, and foreshadows the great difficulty in proper organisation of radiation treatment which will be caused by this attitude on the part of practitioners, and the public assent given to it through ignorance. He deprecates the supply of radium—which may be insufficient in quantity or contained in out-of-date apparatus—to small local hospitals, and the hire of radium by practitioners who order it as they would a drug. The abuse of X rays is, he thinks, less harmful than the abuse of radium.

> "The mischief of bad rontgenotherapy lies not so much in that it deprives patients of treatment by other methods which might cure them, as that it deprives internal radium

The Board wishes to establish these hospitals as a centre, the outlying hospitals doing the general work and referring the special work to the main centre. As the Brisbane General Hospital is somewhat out of date the Board are rebuilding and remodelling it, and it is proposed to build a new hospital to replace the Obstetric Hospital. In the remodelled General Hospital, special complete departments will be established among others for urology, ophthalmology, ear, nose, and throat work, and orthopædics. Each of these departments will be a complete and separate unit. It is hoped to establish later a complete cancer department. A radium department is already in existence, about half a gramme of radium having been lent by the Commonwealth Government for the purpose.

The Pan-Pacific Surgical Conference.

The Pan-Pacific Surgical Conference is being held under the auspices of the Pan-Pacific Union from August 14th to 24th, at Honolulu. The Conference has been organised by Hawaian committees under the general chairmanship of Dr. Nils P. Larsen, and by Pacific Coast States and British Columbian committees under the chairmanship of Dr. George W. Swift. There are 16 sections whose programmes are entirely American, and several symposiums will be prepared. The invitations have been sent to many countries and ten delegates from each Pacific country are being housed and entertained by the committee in Hawaii. Australian delegates are Sir James Barrett, R. H. Pulleine, N. D. Royle, S. Harry Harris, R. P. W. Francis, and Prof. Watson. It is possible that Prof. W. A. Osborne will also attend as a delegate. The objects of the Conference are: to bring together surgeons from countries bordering on the Pacific; to permit the exchange of surgical ideas and methods; and to develop an "acquaintanceship among the surgeons."

UNITED STATES OF AMERICA.

(FROM AN OCCASIONAL CORRESPONDENT.)

The American Medical Association.

THE eightieth annual convention of the American Medical Association was held at Portland, Oregon, from July 8th–12th. The report of the Board of Trustees records that the Spanish edition of the Association's *Journal* was discontinued after the edition of Dec. 15th, 1928. A number of the South American subscribers transferred their allegiance to the English edition. The special technical journals have all enjoyed an increase in circulation, while the popular magazine *Hygeia* has continued to gain and is now on a self-supporting basis. The fact that it reaches monthly nearly 15,000 school teachers gives an idea of its educational influence in this country. The Bureau of Health and Public Instruction has been responsible for a number of radio lectures broadcasted from Chicago. Some of these health talks have been mimeographed and are available at the offices of the Association.

The Committee on Scientific Research reported expenditure during the year of over $12,000 on grants for research. Except in a few cases this money was devoted solely to necessary expense in connexion with research. The Committee on Trachoma among the Indians recommended that all matters relating to the health of the Indians ought to be transferred to the United States Public Health Service "which has a record of efficiency that is in striking contrast to the dismal failures of the Indian Service." Their investigations had shown them that trachoma is not being treated with any thoroughness, that children with this disease are present in all the schools which they visited and mingle freely with healthy children, thus spreading the infection. They add that "almost none" of the hospitals come up to the standards set by the American Medical Association or the American College of Surgeons.

The subject of fee-splitting was dealt with frankly in the report of the Judicial Council. Some physicians have attempted to find a qualified defence of this practice in the wording of a sentence in the Association's Principles of Medical Ethics, which says that "it is also unprofessional to divide a fee for medical advice or surgical treatment, unless the patient or his next friend is fully informed as to the *terms of the transaction.*" *In order that the intention* of this section should be expressed in unequivocal language the Judicial Council recommended an amendment to read: "When a patient is referred by one physician to another for consultation or for treatment, whether the physician in charge accompanies the patient or not, it is unethical to give or to receive a commission by whatever term it may be called or under any guise or pretext whatsoever." This amendment was warmly endorsed during the convention by the Reference Committee on Legislation and Public Relations and was adopted by the House of Delegates at its second session. The House also adopted a resolution disapproving the recent change in policy of the American Red Cross permitting their nurses to serve patients under the care of osteopaths and chiropractors. At the final meeting opposition was raised against a Bill now before the U.S. Senate Committee, which seeks to impose prohibitive tariffs on foreign surgical instruments, X ray equipment, vacuum tubes, valve tubes, and scientific glassware. It was pointed out that these proposals, if adopted, would add materially to the already high cost of medical care. The resolution was referred to the Board of Trustees.

Public Health Services.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

CITY OF LONDON.

Statistics.—The estimated population of the City was 11,430, which gives a density of 17·3 persons per acre, as compared with about 60 per acre for the County of London. The resident population has steadily declined from 112,063 in 1861 to the present figure. The births numbered 82 and the deaths 140, giving a birth-rate of 7·2 and a death-rate of 12·2. The deaths from pulmonary tuberculosis numbered 13, from other tuberculous diseases 5, from cancer 16, from heart disease 31, from bronchitis 6, from pneumonia, 7, from other respiratory diseases 0, and there were no deaths from influenza. The corresponding rates were tuberculosis 1·57, cancer 1·4, heart disease 2·7, and respiratory diseases 1·7. The five infant deaths gave an infant mortality-rate of 60, and there were three deaths between 1 and 5 years. That one cannot make deductions from the rates for a small population is well illustrated by the fact that Dr. W. M. Willoughby records no deaths from childbirth, whilst in the comparative table for the London boroughs in the County report the childbirth mortality for the City is given as 12·05, evidently calculated on one childbirth death. The small number of births enables a close personal touch to be maintained between the infant welfare centre at St. Bartholomew's Hospital and the city mothers.

Infectious and Other Diseases.

The great majority of the notified infectious diseases were removed to hospital; thus out of 57 only one case each of scarlet fever, erysipelas, ophthalmia neonatorum, and pneumonia was treated at home. There were no notifications of puerperal fever or pyrexia, and there was no call made on the funds set aside for the nursing of measles, influenza, &c. Dr. Willoughby favours the notification of acute rheumatism in children under 16 years and the establishment of supervisory centres for such in London. The new

London regulations for infectious diseases came into operation on Jan. 1st, 1892. Trench fever has been removed from the list. Cases of malaria, induced therapeutically, need not be notified unless the practitioner in charge thinks that the patient is liable to relapses. In the case of enteric fever and dysentery steps must be taken to protect food against contamination by carriers. The question of bakers' itch came under consideration because one of the metropolitan boroughs sought powers enabling its medical officers of health to enter a bakehouse and examine the staff with a view to the detection of such skin diseases. Dr. Willoughby points out that "bakers' itch" is an indication of the excessive presence of worm- and insect-infested flour at the source of supply or at the bakehouse, and that he felt compelled to advise his Committee against the support of such piecemeal legislation. He thinks this should be merged in the larger subject of disease and cleanliness in relation to all foodstuffs, which is at present under the consideration of the Ministry of Health. The hours of the tuberculosis dispensary, established at St. Bartholomew's Hospital, have been rearranged with advantage. Wards are available for the reception of cases presenting difficulties of diagnosis, and the patients treated include residents of the City and workers in the City. The attendances show a decline owing to the removal of chronic cases as the result of the demolition of the Hutchison-avenue property. The corporation have made arrangements to maintain infectious advanced City cases at St. Columba's Hospital, Swiss Cottage. More use has been made of artificial pneumothorax. The tuberculosis dispensary has been put at the disposal of the College of Nursing for the training of health visitor students. In connexion with the V.D. clinic, also at St. Bartholomew's, in-patient treatment has been discontinued in the interests of economy. The number of cases discharged after completion of treatment was 7, and the number of cases who ceased to attend before final tests was 23 before completing the first course, 13 after one or more courses, and 23 after completion of treatment. Of the 476 venereal cases treated during the year, 445 were residents of London, and the remainder lived in the counties of Essex, Herts, Surrey, and Kent.

Atmospheric Pollution.

Records of atmospheric pollution by the analysis of rain-water are kept at Golden-lane, and a table is given showing the comparison, month by month, between Golden-lane and the Meteorological Office, South Kensington on the West and Victoria Park on the East. During most months of 1928 Golden-lane was considerably worse than the western station and very much worse than Victoria Park. In May, however, the western and eastern stations were about the same and Golden-lane nearly twice as bad. In July the Meteorological Office was much the best. In September the Meteorological Office was slightly better than Victoria Park, while Golden-lane was fivefold worse. In December the Meteorological Office and Golden-lane were each about twice as bad as Victoria Park. An observation is also made every midday at the Guildhall by a modern dry method. It was found that during the year the noon impurity, varied from a half to 5 mg. per cubic metre of air, the latter figure including times of fog. Dr. Willoughby thinks the time is approaching when a bright, smokeless fuel will be generally available for open grates and the solution of the domestic smoke problem.

Milk.

Of 48 samples of milk examined for tubercle, 4 gave a positive result. In one of the 4 the follow-up at the farm revealed tuberculous udders. In 2 cases the follow-up was a failure and the fourth was being investigated at the end of the year. Dr. Willoughby is impressed with the ease of application and the greater certainty of the intradermal test. He quotes figures showing that out of 835 non-reactors to the subcutaneous, 122 reacted to the intradermal test, and that the autopsy confirmed the result in all the 94 animals examined post mortem. He gives as advantages of the new tests: the veterinary surgeon's visits are reduced from 8 to 3; the tested animal need not be kept indoors; its milk yield is unaffected; the test is without risk to pregnant or young animals; and doping by tuberculin does not nullify the test, which can be successfully repeated at intervals of 3 weeks. On Oct. 1st, 1928, Article 29 of the Milk and Dairies Order, 1926, came into operation, according to which churns or vessels used for the transport of milk must bear the name and address of the owner in permanent marking and be provided with a lid without openings and so constructed as to prevent the access of dirt to the milk and the return to the interior of any milk which may have been splashed above the lid. Two prosecutions for milk deficient in fat, 13 per cent. and 26 per cent. respectively, were dismissed by the magistrate because he was satisfied that the milk was delivered as given by the cow. The veterinary officer, Mr. T. D. Young, who has recently paid a visit to Australia and New Zealand to inspect the meat industry in those countries on the invitation of their Governments, taking the meat industries of U.S.A. and Canada en route, reports on meat inspection.

Meat.

Argentina, during 1928, sent to us 470,000 tons of beef, 100,000 tons less than last year, but 76 per cent. of our imported beef. Australia sent 8 per cent. and Uruguay 6 per cent. New Zealand sent nearly 50 per cent. of our imported mutton and lamb, while Argentina sent 27 per cent., Australia 9 per cent., and Uruguay 7 per cent. New Zealand sent nearly half of the imported frozen pork, whilst the Irish Free State increased her shipments of fresh pork by 3500 tons. Denmark supplied 60 per cent. of our imported bacon and Holland 11 per cent. It was hoped that the removal of the embargo against Canadian cattle would increase our supplies of fat and store cattle, but this has not happened, because the Canadians have been able to obtain more money for such animals in Chicago. The Irish Government have passed a new meat inspection law under which meat inspectors will be appointed in Ireland in all places from which meat is exported to Smithfield. All the countries which export mutton and lamb to Smithfield are suffering loss from the condemnation of carcasses affected with caseous lymphadenitis—namely, Argentina, Australia, New Zealand, Chili, and Uruguay—and determined efforts are being made in every case by the Governments concerned to improve the method of examination of the carcasses and offal at the places of slaughter. Mr. Young mentions that Argentina has sent, experimentally, small consignments of "chilled" instead of frozen mutton, and that the appearances of these carcasses during the autumn and winter was so good that it was very difficult to distinguish them from home-killed mutton. The conditions under which meat has been handled and transported to and from the City markets improved greatly during 1928, and in the great majority of cases verbal caution as to thoughtless contraventions of the regulations was all that was required.

Housing.

Dr. Willoughby has made an inspection of all the dwelling houses in the case of which demolition might seem desirable, and he has formed the opinion that the housing question in the City is not now one which would justify the City Corporation in embarking upon any further housing schemes. The City pigeons were reduced by about 2000 during 1928.

Rats.

Dr. Willoughby states that there is a great decrease in the rat population, that owing to constant attention to drains and sewers the brown rat is fast disappearing, and that as new buildings replace old the lessening in number of the smaller black rat will be apparent. Unfortunately, the owner is not responsible for the rat-proofing of buildings, which is a very expensive matter. If the drains are out of order the owner can, of course, be called upon, and this is one effective way of reducing the number of brown rats. Examples of specifications for rat-proofing against the black rat are given in Dr. Willoughby's report and illustrate graphically the expense involved. Present observations suggest that the black rat in the City outnumbers the brown rat by 3 to 1. Poisons and viruses are not much used in the City. The traps which give the best results are the "breakback" and varnish traps—the latter being now in general use and the most successful of all. Some of the wire traps are constructed of wire so fine that captured rats can force their way out.

TYNE PORT SANITARY AUTHORITY.

IN his annual report to this authority Dr. W. E. Harker mentions that during 1928 9377 ships arrived, of which 8431 were inspected. Single cases of measles, mumps, and enteric fever were removed to hospital, but no cholera, plague, or yellow fever came to notice. Defects were noted in 607 ships (side ports defective in 318, water-closets in 122) and dirty accommodation for crews in 877—i.e., 12 per cent. of British and 6 per cent. of foreign ships. Uncleanliness *is likely to develop at the end of a voyage*, and in this connexion it has been pointed out that the crews of British ships are paid off in British ports, whereas foreigners are not. Except 800 tons of wheat sent to Rotterdam, the food imported was found in good condition. The aliens arriving were all clean. Treatment for venereal disease is offered to every ship on arrival; we are not told whether it is ever accepted. There is an official rat-catcher and on 67 vessels 2628 rats were destroyed, none of which were found to be infected with plague. On account of infection, 1057 beds were burnt. Fishing boats are inspected and 20 were cleansed and deodorised. The 18 water-boats were in good condition, and the water of 25 ships was changed; these also had their tanks purified.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED AUGUST 3RD, 1929.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 129 (last week 129); scarlet fever, 1776; diphtheria, 812; enteric fever, 50; pneumonia, 688; puerperal fever, 24; puerperal pyrexia, 98; cerebro-spinal fever, 13; acute poliomyelitis, 14; acute polio-encephalitis, 1; encephalitis lethargica, 30; dysentery, 6; and ophthalmia neonatorum, 115. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the Metropolitan Asylums Board on August 6th–7th was as follows:—Small-pox, 134 under treatment, 0 under observation (last week 161 and 9 respectively); scarlet fever, 1353; diphtheria, 1520; enteric fever, 12; measles, 314; whooping-cough, 295; puerperal fever, 23 (plus 18 babies); encephalitis lethargica, 123; "other diseases," 22. At St. Margaret's Hospital there were 17 babies (plus 9 mothers) with ophthalmia neonatorum.

Deaths.—In the aggregate of great towns, including London, there were no deaths from small-pox, 5 (2) from enteric fever, 33 (4) from measles, 2 (0) from scarlet fever, 26 (3) from whooping-cough, 18 (6) from diphtheria, 60 (13) from diarrhœa and enteritis under two years, and 20 (1) from influenza. The figures in parentheses are those for London itself.

Three of the deaths from measles were reported from Stoke-on-Trent, 3 from Manchester, and 6 from Liverpool. Those from whooping-cough included 4 from Sheffield, and 3 each from Walsall, Birmingham, and Liverpool. Nine of the deaths from diarrhœa and enteritis under two years were recorded from Liverpool, 4 from Hull, and 3 each from Stoke-on-Trent, Birmingham, and Manchester.

The number of stillbirths reported during the week was 251 (corresponding to a rate of 30 per 1000 total births), including 42 in London.

Death from Small-pox.

Dr. Vynne Borland, medical officer of health for the metropolitan borough of Bethnal Green, informs us that in the fatal case of small-pox recorded last week the patient was an unvaccinated boy aged 13. On July 7th, the day after the rash appeared, he was taken to the South Wharf Hospital, Rotherhithe, and for the following details we are indebted to Dr. W. J. A. Coughlan, assistant medical officer in the River Ambulance Service. The patient was admitted with an attack of confluent small-pox, accompanied by severe toxæmia. He had suffered for eight years from suprapubic fistula, the result of an accident at the age of 4 years, which caused damage to the bladder and urethra. As a direct result of the attack of confluent small-pox a general septic condition supervened from which he died. "The fatal result in this case," writes Dr. Coughlan, "must be regarded as more directly due to the severity of the small-pox infection than has been the case in previous fatalities which have followed the existing mild form of the disease."

We understand that the cause of death was certified as septicæmia, confluent small-pox, and vesical fistula.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Comdr. H. B. Hill is placed on the Retd. List with rank of Surg. Capt.

Surg. Comdr. W. I. Gerrard is placed on the Retd. List at own request.

ROYAL NAVAL VOLUNTEER RESERVE.

Surg. Lt.-Comdr. G. McConll to *Victory*, for R.N. Hospital, Haslar, for training.

Surg. Lts. G. H. Bradshaw, F. E. Stabler, and C. H. A. Fido (D.) to *Victory*, for R.N. Hospital, Haslar, for training.

ROYAL ARMY MEDICAL CORPS.

Capt. F. T. Boucher, late R.A.M.C., T.F., to be temp. Capt., and temporarily relinquishes the rank of Capt.

ARMY DENTAL CORPS.

Lt. L. A. Barlow to be Capt.

TERRITORIAL ARMY.

Lt.-Col. (Bt. Col.) P. J. Gaffikin, from T.A. Res. of Off., to be Lt.-Col. (Bt. Col.).

Maj. F. H. White, having attained the age limit, retires and retains his rank, with permission to wear the prescribed uniform.

INDIAN MEDICAL SERVICE.

Maj. M. Purvis retires.

Lt. (on prob.) J. Acheson to be Capt. (prov.) (on prob.).

DEATHS IN THE SERVICES.

Colonel Alfred Peterkin, C.B., A.M.S., retired, who died at Queen Alexandra's Military Hospital, Millbank, on July 17th at the age of 75, graduated in medicine at the University of Glasgow in 1878. He was a man of magnificent physique, and an old Rugby International, playing for Scotland. He entered the Army Medical Service as surgeon in 1880. In the following year he saw service in the Transvaal War, and in 1902 in the South African War, and received the Queen's medal and two clasps. As an administrative officer he was later employed in Mauritius, South Africa, and in London up to the time of his retirement in 1911. At the beginning of the late war he rejoined for service and was appointed to the charge of the London Command. He had an up-hill fight, as in addition to the ordinary army duties of his position, which in peace time were comparatively slight, he had to deal with five Territorial Hospitals, many private hospitals, the Territorial Units of the two London Divisions (amounting to over 60 Units), all of which, as well as the Guards and the Central Recruiting Depôt at Whitehall, were working briskly. After a short time crowds of wounded arrived, while medical officers were very scarce, and Peterkin dealt manfully with the situation as far as his responsibilities went. A steady, level-headed, and imperturbable officer, Colonel Peterkin was beloved by his juniors and thought much of by his seniors, and when he did not always see eye to eye with the authorities he carried out all orders loyally and thoroughly. He was made a Companion of the Bath during the war. Latterly he did some work for the Ministry of Pensions, and finally joined the Pensions Appeal Tribunals.

Correspondence.

"Audi alteram partem."

A MEMORIAL TO FERNAND WIDAL.

To the Editor of THE LANCET.

SIR,—The enclosed letter explains itself and I propose to do what these distinguished Frenchmen ask me. Will you kindly receive subscriptions for me and allow me to state that I should like myself to subscribe 3 guineas?

I am, Sir, yours faithfully,
ALMROTH WRIGHT.

St. Mary's Hospital, Paddington, August 13th, 1929.

Prof. ALMROTH WRIGHT.

MONSIEUR ET CHER COLLÈGUE,

Les admirateurs, les amis et les élèves du Professeur Fernand Widal ont décidé de former un Comité d'honneur pour perpétuer sa mémoire et répandre son œuvre scientifique. Dans ce but, ils ont l'intention de lui élever un monument, de faire figurer son effigie en médaillon à la Faculté de Médecine et à l'Hôpital Cochin et de publier une édition de l'ensemble de ses travaux.

Un certain nombre de nos collègues étrangers nous ont exprimé le désir de se joindre à nous et nous avons accepté avec joie leur concours.

Nous vous serions reconnaissants de bien vouloir prendre l'initiative de pressentir à ce sujet les personnalités de votre pays qui ont entretenu des relations avec le Professeur Widal et qui gardent pieusement son souvenir. Nous serions heureux de les voir se grouper autour de vous en un comité qui se chargera de recueillir les souscriptions et qui nous aidera dans l'accomplissement de la tâche que nous nous sommes proposée.

Veuillez agréer, Monsieur et cher Collègue, les assurances de notre considération la plus distinguée.

FERNAND BEZANÇON,
76, Rue de Monceau.
ANDRÉ LEMIERRE,
217, Faubourg Saint-Honoré.
PIERRE ABRAMI,
9, Rue de Lille.
MARCEL BRULÉ,
3, Rue Dufrénoy.
EDOUARD JOLTRAIN,
63, Avenue de Villiers.
LOUIS PASTEUR VALLERY-RADOT,
5, Avenue Constant Coquelin.

⁂ We have recorded this movement in an annotation on page 346. Subscriptions to the Fund can be sent to this office, addressed "Widal Memorial, care of The Editor, THE LANCET."—ED. L.

MILDER VACCINATION.

To the Editor of THE LANCET.

SIR,—It may be of interest if I give a short account of recent experience at Scarborough which bears closely on some of the questions raised in your leading article of August 3rd (p. 233).

Of late years there have been two outbreaks in the town, from October, 1924, to June, 1925 (45 cases), and from January, 1927, to March, 1928 (75 cases). The district is, and always has been, poorly vaccinated, the percentage of infants vaccinated in 1924 and 1925 being 30 in each year, but the vaccinal condition of those attacked affords good evidence of the protection afforded. In the first outbreak, out of 45 cases, 40 were unvaccinated, four were vaccinated in infancy, and in one case the vaccinal condition was unknown; the ages of the four persons vaccinated in infancy were 51, 30, 52, and 63 years. In the second outbreak, out of 75 cases, 67 were unvaccinated and eight were vaccinated in infancy, their ages being 25, 32, 46, 47, 48, 49, 50, and 56. These figures speak for themselves, but it will be noted that in 1927–28 the disease attacked patients as young as 25, who had been vaccinated in infancy, and this clearly points to the necessity of *recent* vaccination.

In the first outbreak, of the unvaccinated cases three were vaccinated by the medical officer of health after exposure to infection, but (as it proved) too late to stave off the attack. Vaccination must be successfully performed within three days of exposure to the disease, if the attack is to be averted.

As public vaccinator, I found much opposition to vaccination in Scarborough; only a small proportion take advantage of the conscientious clause on conscientious grounds, and the majority use it as a means of escaping the extra care entailed in attending to a vaccinated arm. Some still think that vaccination will cause the child to develop some other disease, chiefly tuberculosis. The percentages of vaccinations in infants (to births), quoted earlier, give no real idea of the vaccinal condition of the town before and during the two outbreaks. Thus my vaccination register shows that in F. School, out of 178 children vaccinated, 165 had never been vaccinated before; in S.M. School, out of 128 children, 112 had never been vaccinated before; in C. School, out of 225 children, 195 had never been vaccinated before; in the vaccination centre at E., out of 69 persons vaccinated, 52 had never been vaccinated before; and in the centre at S.S., out of 12 persons vaccinated, 8 had never been vaccinated before. The figures for the high school were much better; out of 56 vaccinated, 30 had never been vaccinated before.

During the two outbreaks a number of revaccinations were performed on children under the age of 10. Most of these were unsuccessful. Of the successful cases the majority showed no more than two scars of a previous vaccination. Incomplete vaccination, as shown by only one or two scars, means incomplete safety, but as the Rolleston Committee point out, multiple insertions may perhaps be reserved for those who desire to obtain the maximum protection at one stage. The instruction to public vaccinators by the Ministry of Health is not to revaccinate any child under the age of 10. The lowest age at which revaccination was successfully performed by me was 7 years. This suggests that during an outbreak of small-pox it is wise to revaccinate children of or above 7 years of age, even if they have previously been successfully vaccinated.

In your leading article you say that "it is probable that the lymph now in use is considerably stronger than necessary," and it is noteworthy that in both the Scarborough outbreaks a violent reaction was produced by vaccination in a large number of cases. This reaction is of special significance in the presence of the prevalent mild type of small-pox, since the vaccinal reaction was often more severe than the disease itself. Most cases of small-pox progressed well after the appearance of the rash, whilst many cases of vaccination were confined to bed for as long as a week. Some children were absent from school for two or three weeks. Cases of this violent reaction were chiefly children of school age, and I estimate the percentage as about 20. In most of them on the eighth day the arms appeared to be taking a normal course, but during the next two or three days this reaction had set in. Fever (with temperature often as high as 103° F.), delirium, headache, backache, vomiting, pronounced weakness, and vertigo were common. The arm showed a varying amount of inflammation, from red rings round the vesicles to severe cellulitis extending from the upper arm to the wrist, with redness and œdema. The axillary glands were greatly enlarged and very tender. Supernumerary vesicles were often seen, one child having eight and another ten vesicles from four scarifications. Herpes was frequent on the lips, and one child had a patch of herpes on the breast and neck on the same side as the vaccination.

The same technique was employed in all my vaccinations, and all vaccinations were performed with Government lymph. In a number of cases modifications of the usual method were employed to discover, if possible, any factor which might have some bearing on the production of this reaction. Thus different antiseptics were used to cleanse the skin; the scarifications were made with varying severity, or only half the usual quantity of vaccine lymph was used. No such factor was discovered. It was observed, however, that infants of 4 or 5 months who were vaccinated during the outbreaks did not show the same violent reaction. From this it appeared that the actual presence of small-pox in school-children was an important factor in causing this violent reaction. I may here note that in the first outbreak of small-pox 50 per cent. of cases occurred in children of school age, whilst in the second outbreak the figure was 60 per cent.

A similar violent reaction occurred during the 1923 epidemic in Gloucester, and my experience at Scarborough indicates that in the presence of the present type of mild small-pox Government lymph is too potent. Unfortunately, in the words of the Rolleston Committee there is still "a great lack of information as to the minimal dose of lymph necessary to secure adequate immunity from small-pox."

I am, Sir, yours faithfully,

NATHAN WALSH, M.B., Ch.B.

Scarborough, August 9th, 1929.

MEDICAL EDUCATION.

To the Editor of THE LANCET.

SIR,—The report of Prof. T. J. Mackie's address on medical education, published on p. 298 of your last issue, affords food for thought. I believe that medical men underrate the biological concept of man, of brain + muscle, supported by a bony framework (the skeleton). Much in our teaching of physiology, anatomy, and psychology would benefit by a greater appreciation of this concept, and its corollary the physiological properties of thought. This question, of course, is a big one and is outside the scope of this letter, which is to suggest a few practical ways whereby the student's course can be shortened and simplified with advantage. My suggestions are:—

1. That the students after their first M.B., or its equivalent, be brought into the wards by their physiological teacher to perform the routine pathology of the wards—e.g., the blood-sugar and urea estimations, examinations of the urines, and blood examinations, &c.; and that they should go to all the elementary classes on bacteriology, morbid anatomy, morbid histology, &c., which they now attend after their second M.B. The students at this stage are not taught their clinical physical signs till after, we will say, nine months, but they might, of course, be shown the salient points of a case illustrating physiological or pathological problems. The pathologist (of the teaching staff) could then devote himself to the more difficult problems of pathology itself. The physiologist and the pathologist should oppose each other as counsel in law cases do to arrive at the truth, and each be mutually dependent on each other for his knowledge.

2. That all the present pass examinations should be abolished and the other examinations modified. Instead of them a class-mark should be given and a viva-voce examination held at the end, say, of every six months.

A clever student should be able to pass through the course more quickly than a dull one; as things now stand all students (except those that fail in their examinations) are reduced to the same level; they all pass the first M.B. together, they all pass the second M.B. together, and when they arrive in the wards they all have to start at the same level again; and at the end of their course (five years) not very much, it seems to me, is known of their abilities, or for what branches of the profession that they are fitted; a future researcher, for instance, may be caught young, and helped and educated for that purpose. The present faulty state of affairs was lucidly described in Prof. Lovatt Evans's address before the British Association at Glasgow last year (THE LANCET, 1928, ii., 535).

It seems to me that in our teaching of medicine we might well emulate the law (as mentioned before) in respect to its method of arriving at and of assessing the truth, thus obviating *inter alia* watertight compartments of knowledge.

I am, Sir, yours faithfully,

A. H. MILLER, M.D. Camb.

Bournemouth, August 9th, 1929.

EARLY TREATMENT IN ACUTE ANTERIOR POLIOMYELITIS.

To the Editor of THE LANCET.

SIR,—I do not think it would be superfluous to remind ourselves that an epidemic of acute anterior poliomyelitis is very liable to occur at this particular period of the year. It will be remembered that the epidemic of 1926 started that summer and reached its height during the drought. During that epidemic I saw over 150 cases, chiefly in Essex. I was fortunate enough to treat most of them from the very onset of the disease. This was at their own homes, or in fever hospitals, or at the various hospitals to which I am attached. In addition to the ordinary orthopædic treatment it was also possible to give suitable cases the serum from convalescent or chronic cases of the disease with encouraging results. History may be repeating itself, as I have already seen a number of acute cases within the last few weeks.

I would, therefore, plead that the orthopædic surgeon should be allowed to treat the patients, wherever they may be, in fever hospital or elsewhere, from the moment of the onset of the disease, thereby following out, to the minutest detail, the teaching of Sir Robert Jones that the affected muscles should have *immediate* complete and absolute rest in the orthodox positions necessary for optimum utility after the acute stage has passed.

I am, Sir, yours faithfully,

B. WHITCHURCH HOWELL.

Weymouth-street, W., August 7th, 1929.

THE LATE DR. MITCHELL BRUCE.

To the Editor of THE LANCET.

SIR,—I read with a sense of personal loss and keen regret of the death of Dr. J. Mitchell Bruce. I was fortunate enough in 1888 to be with him as a post-graduate at Brompton, and from his lips learned much that I have, year after year, transmitted to my students at the Jefferson Medical College of Philadelphia. The description of his character and methods in your notice of his death is excellent. Of him it may be said: Doctor et scriptor clarissimus, vir carissimus.

I am, Sir, yours faithfully,

Philadelphia, July 23rd, 1929. HOBART AMORY HARE.

AURAL DISEASE AND BATHING.

To the Editor of THE LANCET.

SIR,—My friend Dr. Graham Forbes in his kind reply to my letter in your issue of August 3rd gives an account of the tests employed for the purity of swimming-bath water, but he will not quarrel with me when I emphasise that the ultimate test is the clinical test. In this the consensus of specialist opinion seems clear: (1) that the metropolitan swimming-baths are a real source of danger; (2) that open-air and sea-bathing appears less fraught with danger, from which it seems to follow that the contamination of the water is a matter of moment; (3) that the infecting micro-organism is a streptococcus. There are many loop-holes for error in the bacteriological testing of swimming-baths and the chemical purification of the water possibly by some untrained person. The clinical test remains, and I venture to think that a case has been made out for the scientific reinvestigation of the question with a view to finding the condition of affairs *at its worst.* I should be happy to think that perhaps such work might fall within the scope of Dr. Forbes's own official researches.—I am, Sir, yours faithfully,

August 12th, 1929. F.R.C.P.

Obituary.

EDWARD OCTAVIUS CROFT, M.D. DURH., L.R.C.P. LOND., M.R.C.S. ENG.,

LATE PROFESSOR OF OBSTETRICS IN THE UNIVERSITY OF LEEDS.

Edward Octavius Croft, who died at Headingley, Leeds, on August 7th, was the son of the late Charles Ilderton Croft, F.R.C.S., of St. Laurence Pountney, London, and received his education at University College, London, from whence he qualified with the double English diploma. The branch of medicine in which he later specialised was early indicated by his appointments as resident obstetric assistant to University College, London, resident medical officer to the General Lying-in Hospital, and registrar and pathologist to the North-Eastern Hospital for Children. When in 1885 a new department consisting of an out-patient and in-patient department for the diseases of women was instituted at the Leeds General Infirmary there was also started an extern department for midwifery, the first hon. officer of which was the late Dr. James Braithwaite; Croft being elected resident obstetric officer, the organisation of the extern midwifery department was then to a large extent left in his hands. Such a department was new to Leeds, where until that time the students had gained their experience in midwifery from private practitioners for the most part, and partly from the obstetric work in the workhouse infirmaries. Croft started on a course of reform with tact and vigour, and in a short time the midwifery training in Leeds assumed a new and much more satisfactory position. It is not too much to say that the department was mainly the result of his efforts, for Dr. Braithwaite, with full confidence, left the organisation in his hands.

In 1898 Croft graduated as M.D. Durh. and became demonstrator of obstetrics at the Yorkshire College, and in 1910 he was appointed lecturer in gynæcology in the University of Leeds and subsequently professor of obstetrics. He was also honorary consulting physician to the Workwomen's Convalescent Home at Ilkley, senior hon. surgeon to the Leeds Hospital for Women and Children, and hon. surgeon to the Leeds Maternity Hospital. He was a past president of the North of England Obstetrical and Gynæcological Society and also of the Leeds and West Riding Medico-Chirurgical Society, and acted as an examiner to the Central Midwives Board. Although he was not a prolific writer, he contributed to the transactions of the different societies dealing with the branch of medicine in which he was specially interested, and occasionally to our columns.

In private life Croft was a deservedly popular man. A colleague writes of him: "He was one of the straightest men I have ever met, absolutely honest in every way. An amusing companion, his ready sense of humour showed itself in the way in which he organised regularly the Christmas entertainments at the Leeds General Infirmary."

Medical News.

UNIVERSITY OF LONDON.—Applications are invited for the *William Julius Mickle Fellowship*, of the value of at least £200, which is awarded annually by the Senate to the man or woman who, being resident in London and a graduate of the University, has in the opinion of the Senate done most to advance medical art or science within the preceding five years. Applications must be made in proper form to the Principal of the University not later than Oct. 1st. Particulars may be had on application.

INTERNATIONAL MEDICAL CLUB OF NEW YORK.—Members of the medical profession who intend to visit the United States are informed by the International Medical Club of New York that one of the aims of the Club is to receive and direct such visitors during their sojourn. The objects of the Club are set out in a leaflet which can be obtained from the Chairman of the Liaison Committee, Dr. Fred H. Albee, 30, East 40th Street, New York City; they are briefly the promotion of social and academic relations between medical graduates in America and the establishment of a friendly and scientific union between the Club and organisations with similar aims in foreign countries. It is hoped to get into touch with representatives of medicine in all countries, and ascertain what post-graduate medical opportunities are in existence. The president of the Club is Dr. Jacques W. Maliniak.

DISEASES OF THE NERVOUS SYSTEM.—A post-graduate course on this subject will be held at the National Hospital, Queen-square, from Oct. 7th to Nov. 29th. The general course will consist of 32 clinical lectures and demonstrations at 3.30 P.M. each weekday, except Wednesday and Saturday. There will be teaching in the out-patient department on each weekday except Saturday at 2 P.M., and eight pathological lectures and demonstrations on Mondays at noon. A course of eight lectures on the Anatomy and Physiology of the Nervous System will be arranged on Fridays at noon if there are enough applicants, and 12 clinical demonstrations, chiefly on Methods of Examination of the Nervous System, will be given on Tuesdays and Thursdays at the same hour. Tickets entitling the holder to attend the out-patients clinic may be obtained, and a limited number of students can be enrolled as ward clerks. Application should be made to the Secretary of the Medical School, National Hospital, Queen-square, London, W.C.1.

MATERNITY INSTITUTIONS.—The Scottish Department of Health has approved of the Glasgow Corporation's proposal to build a new maternity hospital. The institution, which will accommodate from 100 to 150 beds, will provide treatment for patients who are unable to pay for nursing-home charges. A site has not yet been selected.—The annual report of the Maternity Centre for Holborn, Finsbury, and the City Border records a busy year. There are 420 mothers on the register, and the superintendent paid 1381 visits. Consultations by doctors dealt with 2206 mothers and 2824 children. The honorary physicians state that "there has been no very marked falling off" in the physique and nutrition of 'the children in consequence of the unsatisfactory economic conditions caused by unemployment and short time.

INTERNATIONAL ASSOCIATION FOR THE PREVENTION OF TUBERCULOSIS.—As we have already announced, the fifteenth annual conference of this Association will be held in the Connaught Hall, Newcastle-upon-Tyne, from Oct. 10th–12th. On the first day, after a formal opening of the Conference by the Lord Mayor, Mr. Henry Mess, Ph.D., will give an address entitled Tuberculosis on Tyneside: a Sociological Survey, and a discussion will follow. In the afternoon Dr. Edouard Rist, of Paris, will speak on the Factors that Produce Pulmonary Tuberculosis, a subject which will be discussed by Dr. A. F. Bernard Shaw, Dr. C. G. R. Goodwin, Sir Thomas Oliver, and others. On Oct. 11th Dr. William Brand will set out a Scheme of National Propaganda regarding Tuberculosis, and later Dr. A. H. Macpherson will give an address on Combined Treatment and Technical Education of Tuberculous Youths. In each case a discussion will follow. Other subjects to be considered include the Teaching of Tuberculosis to Undergraduates (introduced by Prof. Thomas Beattie and Dr. Fergus Hewat), the Training of Tuberculosis Medical Officers (Dr. W. H. Dickinson), Methods of Medical Propaganda regarding Tuberculosis (Dr. Harley Williams), and Dentistry in Relation to Tuberculosis (Dr. William Guy). The address of the Association is 1, Gordon-square, London, W.C. 1.

WORLD LEAGUE FOR SEXUAL REFORM.—The third International Congress of the World League for Sexual Reform on a Scientific Basis will be held at the Wigmore Hall, Wigmore-street, London, W. 1, from Sept. 8th to 14th. The hon. secretary is Dr. Norman Haire, and communications may be sent to him at 127, Harley-street, London, W. 1.

POST-GRADUATE COURSE IN NEUROLOGY AND PSYCHIATRY.—Under the auspices of the American Medical Association of Vienna systematic post-graduate classes in English will be held at Prof. Wagner-Jauregg's Neuro-Psychiatric Clinic and at the Neurological Institute of Prof. Marburg in the University of Vienna from Jan. 2nd to Feb. 15th, 1930. Further information may be had from Dr. E. Spiegel, Falkestrasse 3, Vienna, I.

BRITISH SOCIAL HYGIENE COUNCIL.—Mr. L. S. Amery, M.P., late Secretary of State for Dominion Affairs and for the Colonies, has accepted the chairmanship of the Imperial and International Committee of this Council. It is stated that arrangements are being made for providing missionaries and other social workers who are going abroad with a knowledge of the problems of social hygiene. In this connexion a diploma course has been instituted at Aberystwyth University and others are in view.

INTERNATIONAL TRACHOMA PRIZE.—The Royal Hungarian Minister of Public Welfare and Labour offers a prize of 2000 Swiss francs for an essay embodying independent work on the ætiology of trachoma. Papers already published are eligible for the competition, and the judges may also consider work not submitted for competition, but published between July 1st of this year and June 30th, 1931. Essays may be written in German, English, French, Italian, or Hungarian, and should be sent to the Eye Clinic No. 1 of the Royal Hungarian Peter Pázmány University (Budapest, VIII., Mária-utca 39) not later than June 30th, 1931.

POST-GRADUATE COURSES IN FRANCE.—Dr. C. Laubry is to give a course on Diseases of the Heart and Vessels at the Hôpital Broussais, Paris, from Oct. 7th to 19th. Particulars from Mr. Thiroloix at the hospital. —From Nov. 4th to 16th Prof. Georges Mouriquand and his colleagues will hold a course in pædiatrics at the Clinique Médicale Infantile of the University of Lyons. Application should be made to the Secrétariat de la Faculté de Médecine, 18 quai Claude-Bernard, Lyon, before Oct. 25th.

DONATIONS AND BEQUESTS.—Mr. Francis James Hillier, of Queen's-road, Peckham, left £500 each to Sir William Treloar's Hospital for Cripples, St. Dunstan's Headquarters for Blind Sailors and Soldiers, and Dr. Barnardo's Homes.—Alderman Robert Harold Posnett, of the Mount, Moughland-road, Runcorn, Cheshire, left £500 each to the National Children's Home, Posnet House, Frodsham, and the Runcorn Cottage Hospital.—Mrs. Eliza Andrews, of Ardara, Comber, Co. Down, left £100 to the Comber Nursing Association, and £200 to the Royal Victoria Hospital, Belfast.—Mr. Michael Rogers Oldfield Thomas, of Edward's-square, Kensington, besides other bequests, left £3000 to the London Hospital.—Mrs. Margaret Inglis or Breen, of Broomhide House, Partick, Glasgow, left £2000 to the Royal Hospital for Sick Children for a "Margaret Inglis Breen Ward," and £1000 each to the Royal Infirmary, Glasgow, The Western Infirmary, Glasgow, and Victoria Infirmary, Glasgow.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—Courses will be in progress for another week at the All Saints' Hospital (urology) and at the Queen's Hospital for Children (pædiatrics). The former is an afternoon and evening course and the latter lasts all day. Special courses in the following subjects will be given during September: diseases of the chest, Brompton Hospital, Sept. 9th to 14th; diseases of infants, Infants Hospital, Sept. 9th to 22nd; psychological medicine, Bethlem Royal Hospital, Tuesday and Saturday mornings, Sept. 10th to Oct. 5th; medicine, surgery, and the specialties, Westminster Hospital, for men only, Sept. 16th to 28th. An all-day course in gastro-enterology will be held at the Prince of Wales's Hospital, Tottenham, from Sept. 30th to Oct. 4th. The Metropolitan Hospital will hold its first course under the auspices of the Fellowship, in medicine, surgery, and the specialties, from Oct. 21st to Nov. 2nd. This will be an all-day course. The Fellowship proposes to hold another evening course for the M.R.C.P. examination, from Oct. 15th to Dec. 6th, consisting of 16 lectures on Tuesdays and Fridays at 8.30 P.M., at 11, Chandos-street, W. 1. Full particulars of the above and other courses may be had from the Secretary of the Fellowship at 1, Wimpole-street, London, W. 1.

WELFARE OF MERCHANT SEAMEN.—The second international conference on the health and welfare of merchant seamen will be held at Geneva from Oct. [illegible]. Particulars are obtainable from Dr. F. H[illegible], League of Red Cross Societies, 2, Avenue Velasquez, Paris.

GIFTS OF RADIUM TO HOSPITALS.—It is stated that a visitor to Westminster Hospital on August [illegible] for the purchase of radium. He did not give his name.—Another anonymous donor has presented £[illegible] worth of radium to the King Edward VII. Hospital at Windsor, where a department for radium therapy will shortly be opened.

MEDICAL RESEARCH COUNCIL.—Under the auspices of the Council H.M. Stationery Office is about to publish a "System of Bacteriology in Relation to Medicine" in nine volumes, each of some 400 pages. The aim of the system, it is stated, is "to give a comprehensive but not encyclopædic survey of our present knowledge of bacteria and spirochætes, with special regard to their relations to the various fields of medical work." It is being prepared by nearly 100 British bacteriologists, each of whom will treat of subjects in which he has taken special interest; each article will represent the judgment of its author on the present state of knowledge, based upon the published work of others and his own experience. Volume [illegible] is the first volume to appear and will be available within a day or two.

PEMBROKESHIRE WAR MEMORIAL HOSPITAL.—A new Children's Ward has been opened by Mrs. Lort-Phillips in memory of her husband, the late Colonel J. F. Lort-Phillips, of Laurenny. The opening ceremony was presided over by Lord Kylsant, Lord Lieutenant of Haverfordwest, which enjoys the privilege of being the only borough possessing a Lord Lieutenant.

APPROACHING REMOVAL OF BETHLEM HOSPITAL.—Sir Lionel Faudel-Phillips, the treasurer, in his annual report to the Governors, states that it is hoped to transfer the hospital from Lambeth to the new buildings at Monks Orchard in the course of next year. The Building Fund stands at £47,763, and another £25,000 is needed to start free of debt. During the past year 437 patients were treated, at an average cost of £4 13s. 8d. per head per week. Of the £[illegible] total expended, £14,111 was recovered by payments in respect of patients.

ROYAL SUSSEX COUNTY HOSPITAL.—The late Mr. Bernhard Baron made several large gifts to this hospital, including £10,000 for the casualty ward opened in April. While that work was in progress he announced his intention of giving £5000 towards the provision of a new operating theatre. In 1928 no fewer than 2200 operations had to be performed in the space originally designed [illegible] but the governors decided that all they could do was to improve the existing theatres on the roof of the hospital. Thanks to Mr. Baron's donation, however, these plans have been changed, and on August 6th sanction was given for the erection of a new operating theatre block.

PRESTON INFIRMARY.—Princess Mary on [illegible] opened a new wing and unveiled a memorial [illegible] at the Preston and County of Lancaster Queen Victoria Infirmary. The building cost £10,000 to erect and equip, and consists of a complete hospital unit of three large wards—one for men, one for women, and one for children—with an operating theatre and other accessories and an entirely new accident ward. Provision has also been made for [illegible] private patients who, while wishing to pay part of the cost of their treatment and maintenance, are unable to afford comparatively high fees in a nursing home. With the beds in the new wards and those in the older part of the building, and the beds in the two convalescent hospitals, there is now accommodation for 400 patients.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

MONDAY, August 19th, to SATURDAY, August 24th.—ALL SAINTS' HOSPITAL, Vauxhall Bridge-road, S.W. Special Course in Urology. Afternoons and evenings (last week).—QUEEN'S HOSPITAL FOR CHILDREN, Hackney-road, Bethnal Green, E. Special Course of Instructions consisting of demonstrations, lectures, and operations. Further particulars from the Fellowship of Medicine.

Appointments.

AITKEN, A. G., M.B., Ch.B. Glasg., has been appointed Certifying Surgeon under the Factory and Workshop Acts for the Callington District of the County of Cornwall.

MCLAGGAN, J. D., F.R.C.S. Eng., Consulting Laryngologist to the Metropolitan Asylums Board Sanatoria.

Vacancies.

For further information refer to the advertisement columns.

Barrow-in-Furness, North Lonsdale Hospital.—H.S. £150.

Birkenhead General Hospital.—Cas. S. £100.

Birmingham City Education Committee.—Asst. School M.O. £600.

Birmingham General Hospital.—Res. H.P. £70.

Bolingbroke Hospital, Wandsworth Common, S.W.—H.S. At rate of £120.

Bournemouth, Royal Victoria and West Hants Hospital.—Second H.S. At rate of £120.

Bradford, Municipal General Hospital, St. Luke's.—H.P.'s and H.S.'s. Each at rate of £200.

Brighton, New Sussex Hospital for Women and Children, Windlesham-road.—Hon. Asst. Ophth. S. Also Hon. Anæsthetist.

Burton-on-Trent, General Infirmary.—2nd Res. H.S. £150.

Cardiff City Mental Hospital, Whitchurch.—Res. Clin. Asst. 50 gns.

Cardiff, King Edward VII. Welsh National Memorial Assoc.—Asst. Res. M.O. for Cefn Mably Hospital, nr. Newport. Also 3rd Asst. Res. M.O. for North Wales Sanat., Llangwyfan. Each £250.

Cheadle, Cheshire, Cheadle Royal.—Asst. M.O. £350.

Coventry and Warwickshire Hospital.—Hon. Anæsthetist.

Dundee, Royal Infirmary.—Hon. Asst. P. for Dis. of Children.

East London Hospital for Children, &c., Shadwell, E.—Res. H.S. and H.P. Each at rate of £125.

Exeter, Royal Devon and Exeter Hospital.—Asst. H.S. At rate of £100.

Great Yarmouth General Hospital.—Sen. H.S. £150.

Hull Royal Infirmary.—Second H.S. At rate of £150. Also Cas. H.S. At rate of £130.

Ilford Emergency Hospital.—Hon. Aural Surgeon.

Kingston-upon-Hull, City and County of.—M.O.H. £1500.

Leicestershire Royal Infirmary.—H.S.'s, H.P., &c. Each at rate of £125.

Lincoln, Bracebridge Mental Hospital.—3rd Asst. M.O. £350.

Liphook, Hants, King George's Sanatorium for Sailors.—Asst. M.O. At rate of £200.

Liverpool, Walton Institution, Rice-lane.—Res. Asst. M.O. £200.

London Jewish Hospital, Stepney Green, E.—Cas. O. At rate of £150.

London Temperance Hospital, Hampstead-road, N.W.—Cas. O. At rate of £120.

Longton Hospital, Staffs.—H.S. £120.

Lowestoft and North Suffolk Hospital.—H.S. £150.

Manchester and District Radium Institution.—Asst. Radiologist. £350.

Manchester, Royal Infirmary.—Clin. Asst. £35 for six months.

Mexborough, Montagu Hospital.—Radiologist.

Mile End Hospital, Bancroft-road, Mile End, E.—Res. Asst. M.O. £450.

Milford, Surrey County Sanatorium.—2nd Asst. M.O. £400.

Newcastle-upon-Tyne, Hospital for Sick Children.—Res. Sen. H.S. and Res. H.P. Each at rate of £95. Also Jun. H.S. At rate of £100.

National Hospital for Diseases of Heart, Westmorland-street, W.—M.O. to Out-patients. At rate of £125.

Nottingham General Hospital.—H.P. Also Asst. Res. Cas. O. Each at rate of £150.

Oswestry, Shropshire Orthopædic Hospital and Agnes Hunt Surgical Home.—H.S. £200.

Portsmouth Royal Hospital.—Cas. O. At rate of £100.

Plumstead and District Hospital, Plumstead High-street, S.E.—Third Asst. M.O. £300.

Plymouth, South Devon and East Cornwall Hospital.—H.P. At rate of £120.

Rotherham Hospital.—H.P. £180.

Royal Eye Hospital, St. George's-circus, S.E.—12 Salaried Refractionists. 12 Clinical Assts. Also 1 Pathologist.

Royal Northern Hospital, Islington Tuberculosis Dispensary, Holloway, N.—Tuberculosis Officer. £750.

Royal Waterloo Hospital for Children, &c., Waterloo-road, S.E.—Clin. Assts.

St. Helen's Hospital, Lancashire.—Res. M.O. £250.

Sheffield, Jessop Hospital for Women.—Sen. Res. O. £250.

Sheffield Royal Infirmary.—Jun. Aural and Ophth. H.S. £80.

Southampton, Royal South Hants and Southampton Hospital.—Jun. H.S. Also Cas. O. At rate of £130 and £120 respectively.

Swindon and North Wilts Victoria Hospital.—Hon. Aural Surg.

Tipton Urban District Council.—M.O.H., &c. £800.

Warrington Infirmary and Dispensary.—Hon. Dental Surgeon.

Warwickshire, King Edward VII. Memorial Sanatorium.—Sen. H.P. and Jun. H.P. At rate of £275 and £200 respectively.

Watford, Herts Peace Memorial Hospital.—Res. M.O. At rate of £150.

West Bromwich and District General Hospital.—H.S., H.P., and Cas. H.S. Each at rate of £200.

West London Hospital, Hammersmith-road, W.—Res. Asst. S. £200. H.P., H.S.'s, &c. Each £100. Also Non-Res. H.S. £5 5s. weekly.

Weston-super-Mare General Hospital.—H.S. £130.

Winchester, Royal Hampshire County Hospital.—Res. H.S. £150.

Births, Marriages, and Deaths.

BIRTHS.

BARLEE.—On August 11th, at Hull, the wife of R. J. Barlee, Surg. Lieut.-Comdr., R.N. (retired), of a daughter.

BOURDILLON.—On August 9th, at Stow House, Goring-on-Thames to Sylvia, the wife of L. G. Bourdillon, D.S.O., M.B.—a son.

EVERETT.—On August 5th, at a nursing home, the wife of F. A. Everett, L.D.S., Clapham-road, S.W., of a son.

KEEFE.—On August 3rd, to Dorothy, the wife of Dr. D. E. Keefe, 62, Grafton-road N., Plaistow, E.13—a daughter.

NEWELL.—On August 9th, at Clothorn-road, Didsbury, Manchester, the wife of R. L. Newell, F.R.C.S., of a son.

NUNAN.—On August 8th, at Woodcote Lodge, West Horsley, Surrey, the wife of Patrick Francis Nunan, Kenya Medical Service, of a daughter.

QUENNELL.—On August 8th, at Millfield, near Brentwood, Essex, the wife of W. E. H. Quennell, M.R.C.S., of a daughter.

ROWELL.—On August 7th, at Chapel-street, Belgrave-square, S.W., the wife of G. L. F. Rowell, F.R.C.S., L.R.C.P., of a son (stillborn).

MARRIAGES.

BEARE—HESKETT.—On July 31st, at St. John's Church, Plumpton, Cumberland, Cyril E. Beare, M.B., F.R.C.S., of Dorking, to Annie (Pat) Heskett, of Plumpton Hall, Penrith.

LEYS—TEMPLE.—On August 6th, in London, Duncan Gerard Leys, M.B.Oxf., M.R.C.P. Lond., to Erica Hope, only daughter of Mr. and Mrs. Edwin Temple, Carlton-terrace, Glasgow.

DEATHS.

BUCKLEY.—On August 8th, at Clopton Manor, Kettering, Northants, Thomas William Buckley, M.D., J.P. (late Major, R.A.M.C.), in his 71st year.

CROFT.—On August 7th, at Headingley, Leeds, Edward Octavius Croft, M.D., of 33, Park-square, Leeds.

HOAR.—On August 3rd, at Hollingbury-place, Brighton, Sussex, C. de S. Hoar, L.R.C.P. Lond., M.R.C.S. Eng., aged 69.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

WORLD FEDERATION OF EDUCATIONAL ASSOCIATIONS.

(FROM A CORRESPONDENT.)

THIS Federation was first projected by the present President, Dr. Augustus Thomas, Education Commissioner for the State of Maine. It is quite in the International spirit of the time. Its organisation is broadly based among the nations, and probably education is the one concept whose urgency no nation will dispute. It is certain that the nations, both of the East and of the West, have responded to the idea. The meeting just held in Geneva is the fourth; the first was at San Francisco in 1923; the second at Edinburgh in 1925; the third at Toronto in 1927. There is a desire that consecutive meetings should take place in different continents, but where the next meeting will be has not been formally announced.

The Health Section.

The Geneva meeting was a success, as was right in the home of all "internationalisms," as well as of the League of Nations. The Federation has been for ten days the focal centre for several other conferences and discussions, none of them far from its own central idea, which is to provide a non-party platform for all forms of educational theory, practice, and propaganda. But, from the beginning, the Federation established a Health Section, whose proceedings were of practical value at Edinburgh, Toronto, and again at Geneva, for the work of the Section has served to elicit facts and programmes from over thirty nations, including China, Japan, India, Russia, Poland, Latvia, Esthonia, Greece, Roumania, and several others. Western Europe, as well as Canada and the United States, were well represented. The National Teachers' Union of England and the Educational Institute of Scotland both sent large contingents. Naturally, as the Congress was fundamentally educational, the reports presented and discussed at the Health Section dealt with the health of the school ages, and the various methods attempted and proposed for education in health. But in several of the other sections, notably in the section of Rural Education and Agriculture, and the section of School and Parent, health always emerged, and was universally regarded as a necessary condition of all sound school organisation.

In the Health Section it had been arranged that delegates from leading countries should send in advance copies of books, pamphlets, primary official documents of investigations, of administration, of actual and proposed schemes. These many volumes formed a useful reference library; it was well consulted by the representatives of the younger nations, thus showing the true use of these international discussions. The conference was thus able both to learn from the various delegates how far their countries had got in school health administration, to note their readiness to seize on the views of experience, and to reflect on the numerous questionings. Such conversations, set going by the Congress, will promote the intellectual inter-penetration that forms one condition of a safe internationalism. Dr. Alfred Zimmern, of the League of Nations, head of the Geneva School for Intellectual Co-operation, and the author of "The Greek Commonwealth," which is a vital exposition of political ideas and idealisms, made exactly this point in a plenary address, and the Health Section certainly worked in this spirit.

The Chairman's Questionaire.

Prof. C. E. Turner, of the Massachusetts Institute of Technology, Cambridge, was Chairman of the Health Section, which henceforth will cease to be called the "Health Education Section." He had issued early in the year an elaborate questionaire, and the replies formed a very useful way of obtaining precise information from the various countries and of concentrating the discussions. The broad results were formulated in 16 resolutions. Of the 16, the following were the most important: That health one of the first aims of education; that there is need for further training of teachers in methods of health education; that travelling instructors have been found useful to this end; that large-type text-books are desirable; that physiology and hygiene should form part of the instruction in the public schools of every country; that school medical and nursing service should be provided for schools throughout the world, and school-house sanitation (especially hand-washing facilities) should be improved; that there is need for permanent representation of the Health Section in each country, in order that information and documents concerning the progress made in school health may be distributed internationally; that there should be further study of the continuity and cessation of growth in school-children, as an indication of health status; that there is need for greater continuity in the health records of children between the pre-school and the school period; that the teaching of home hygiene, infant and child care should be made universal for girls of adolescent age; that there is need for the study and development of further tests, in addition to weighing and measuring, for determining the health status of school-children; that further study of dental health is necessary; that every university should provide a student, in addition to athletic organisation and health instruction, with a health service, including preventive medical service, communicable disease control, financial aid in sickness, hospital treatment where necessary, and convalescent care.

Some Outstanding Contributions.

Of individual contributions to the Congress, three stand out clearly; first, the excellent address on the International Aspects of Education, by Prof. Gilbert Murray, whose position in relation to the League of Nations and the detailed work of its committees is well known; second, the practical and elegant address by Prof. Léon Bernard, Head of the Institute of Hygiene in the Paris School of Medicine: on the teaching of hygiene in, by, and through the school, stress being laid on "teaching by example"; third, the lecture at the final meeting by Prof. Paul Monroe, LL.D., now Professor of Education in Columbia University, who drew attention in a masterly way to the great educational experiments made, or being made, in China, Japan, the Philippines, and Russia. To many of the audience who had heard dissertations of all sorts on education for a generation this lecture was one of the most striking, forming an effective climax to a week of strenuous work.

A fourth contribution deserving of mention was the address by Dr. Thomas D. Wood, of New York, who spoke as chairman of the united session of the Home and School and the Health sections; this was the mature deliverance of the veteran author of the well-known height and weight standards, which are widely used as tests of school-age, growth, and nutrition.

The Wide Range of Work.

There were some good contributions to the study of physical education which is now taking its place as a definite method of preventive medicine, and which may become primarily a responsibility upon school medical officers. Communications from Hungary and Poland were exactly illustrative of this point.

From both Belgium, through Monsieur de Vuyst of the Belgian Education Department, and France, through Monsieur Varrier of the French Department of Public Instruction, came a survey of the factors in the problems arising out of the different conditions, as far as education is concerned, which prevail in the town and in the country. Such problems, and many others like it, were discussed especially by American representatives and by American members of the International Parents' Association, for in America the educational position arising from immigration, with the extraordinary mixture of cultures and races resulting, requires perpetual and great adjustment.

When the transactions of the Congress are published they will be found to contain illuminating surveys from which educational authorities in many countries will be able to derive practical information and guidance.

Genéva, August 7th, 1929.

FOCAL SEPSIS IN DISEASES OF THE SKIN.

THE doctrine of focal infection, which has hitherto found its chief supporters in England and America, is now gaining adherents on the continent, and A. M. Memmesheimer, a well-known dermatologist of the younger school in Germany, has published a paper[1] in which he seeks to establish a scientific foundation for the now popular hypothesis.

Considering that the claims put forward by such authors as Roberts, Barber, Nord, Semon, and others are based on clinical evidence only, and on material too scanty for satisfactory proof of the alleged association of cause and effect, he set himself to investigate the doctrine in the case of 60 patients, of whom half were sufferers from chronic eczema, and the other half included 14 cases of psoriasis, four of lupus erythematosus, seven of herpes zoster, two of rosacea, and one each of erythema nodosum and erythema multiforme. These were utilised as controls. Of the 33 eczematous cases, 20 were found to have apical "granulomata" as clearly demonstrated by X rays. Six of the 14 psoriasis patients, one of the four with lupus erythematosus, and four of the seven with herpes zoster, afforded similar evidence of apical infection. The proportion of dental infections in the two groups worked out at 70 per cent. to 51 per cent.

---

[1] Arch. f. Derm. u. Syph., 1929, clvii., 133.

Memmesheimer here raises the important question whether we should regard the preponderating percentage of dental infections in the eczematous group as evidence of a causal factor, or whether people with the cutaneous idiosyncrasy may not have an associated weakness or lack of resistance in their dental tissues. It might further be argued that dental toxins can sensitise the body to some other exogenous or endogenous poison which would not be capable of producing cutaneous symptoms in their absence. In the hope of showing some of these problems, he examined the elective or specific action of the streptococci from dental foci, and endeavoured to elicit some evidence of their presence, or that of their toxins, in the patient's own blood and tissues. Injections into rabbits and mice were tried, both with single large doses and small repeated doses, designed to imitate toxic absorption in human beings. Mice were found to be relatively immune, but of 27 rabbits inoculated with the massive single dose 15 died, and in 9 of them the streptococci were recovered in cultures from the blood. In no single instance were skin lesions produced, nor did such lesions make their appearance in a similar series (27) injected from day to day.

Complement-fixation tests, both of the blood serum and tissue cells, in 14 patients tested to their own strain of streptococci and to foreign strains, were positive in two cases, and that in a restricted sense only. But removal of the infective foci—i.e., the apical granulomata—cleared up the eczema in 5 out of 15 cases, and Memmesheimer holds that the low percentage of positive findings is by no means conclusive evidence against the doctrine of focal sepsis. Further research on the same lines is, he thinks, desirable.

HEALTH CONDITIONS IN THE FALKLAND ISLANDS.

A REPORT prepared by Mr. J. M. Ellis, Colonial Secretary, has recently been issued by H.M. Stationery Office, dealing with the affairs of the Crown Colony of the Falkland Islands and its Dependencies. Geographically the Falkland Islands lie in the South Atlantic Ocean. In addition to the two main islands, known as the East and the West Falkland, the group comprises about 200 small islands clustered around them, within a space of 120 by 60 miles. The Dependencies are divided into two main groups, the one consisting of South Georgia with the South Orkneys and the South Sandwich Islands, and the other of the South Shetlands with Graham's Land. The area of these Dependencies covers 3,100,000 square miles, or approximately one-fifth of the total area of the British Empire. The population of the colony, which at the end of 1927 was 2286, is European, and chiefly of British descent. The birth-rate during that year was 22·31 per 1000, and death-rate 9·26 per 1000. As in previous years, general diseases were rare, with the exception of tuberculosis, which is common. Its prevalence seems to be aggravated by close inter-marriage and by inadequate housing conditions. Steps are being taken to improve the latter; and it is hoped in the near future to organise a scheme to examine sputums, in the hope of discovering the disease at earlier stages. Chronic appendicitis is also prevalent among the inhabitants of the colony. Communicable diseases, mosquito or insect borne, were entirely absent, and no acute infectious condition was reported during the year. Septic throat and cervical adenitis were troublesome.

Particular care is being devoted to the dental treatment of the school-children, who all receive free attendance. An outbreak of bad colds occurred some time ago, and treatment with stock vaccine did not meet with much success. The colony is devoted solely to sheep farming, and all its interests are subordinate to the production of wool.

The Falkland Islands are bleak and the climate is rigorous but healthy. It is trying to people from the United Kingdom on account of the continuous cold, the lack of sun, and the constant high winds, and also because few opportunities are afforded for outdoor exercise.

INTENSIFYING SCREENS.

WE have received a booklet from Philips Lamps Ltd., entitled Intensifying and Fluorescent Screens, which is devoted mainly to a description of intensifying screens manufactured by this firm. The Philips screen is coated on a celluloid base which, it is claimed, is not easily scratched or damaged, and moreover may be washed with water, petrol, or methylated spirit. From a perusal of the pamphlet it is clear that the manufacturer is alive to those qualities, which a fluorescent screen must possess if it is to be efficient.

The use of an intensifying screen for reducing the exposure required to produce a radiogram dates back to 1897. [illegible] that the yellow green fluorescence [illegible] barium-platino cyanide, though [illegible] screens, is relatively ineffective [illegible], which, unless specially prepared, is only particularly sensitive to violet and ultra-violet radiations. Fluorescence of this character is excited in calcium tungstate by X rays which in consequence forms the active layer of modern intensifying screens. The production of calcium tungstate of high photographic activity free from phosphorescence and in a fine state of subdivision, has, however, necessitated a considerable amount of experimental work. The fine detail of many of the earlier radiograms was confused by the impression of the crystalline structure of the screen, and the afterglow from the latter often destroyed the sharpness of the image; but it may be fairly claimed that the modern intensifying screen is free from these defects.

It is common practice to place intensifying screens on both sides of a film, which leads to a considerable reduction in the time necessary to produce a radiogram. From the photographic point of view there is, moreover, the added advantage that the value of the screen is greatest in the lower densities where it is most required, and hence for instantaneous radiography they are invaluable.

Much of the success obtained with intensifying screens depends not only upon the mechanical qualities of the materials used as the foundation for the fluorescent layer, but also on the casette for holding it close to the photographic film. Experience has shown that both must be such that the screen is held in perfect contact with the film at all points during exposure, otherwise blurring of the image may occur and the screen becomes inefficient. How far improvements in these directions have been made may best be judged by the fact that the intensifying screen is now regarded as an essential part of modern radiographic equipment.

VESALIUS AND THE INQUISITION MYTH.

To the Editor of THE LANCET.

SIR,—Some stories seem to be endowed with immortality It is of no consequence that they have no basis in fact; it is enough that they are tinged with some colour of romance, or that their tragic dénouement excites pity, or that they can be used to make a point in controversy. Truth limps painfully behind and never makes up to them. A recent illustration of this is to be found in Prof. A. V. Hill's lecture on the Enemies of Knowledge. As it is reported in your columns (June 29th, 1929, p. 1389), he spoke as follows: "Vesalius was inspecting *with* the consent of his kinsman the body of a Spanish nobleman recently dead; the heart gave a feeble palpitation when divided by the knife. Vesalius was denounced to the Inquisition and driven from Italy." No doubt Prof. Hill believed he was merely stating facts, and yet there is not a single phrase in this description which will bear examination. It is over 30 years since I first published the proof of its falsity, and I went into the matter with greater detail in the *Edinburgh Medical Journal* in 1914. More recently a short summary of the genesis of the myth appeared in THE LANCET (Jan. 11th, 1928, p. 105). The statements I have made have not been controverted. Indeed I do not know any authority on Vesalius who credits the story. All I can claim to have done is to have examined most closely all the contemporary documents relating to that period of the anatomist's life. If, then, Prof. Hill has discovered fresh documentary evidence, he would confer a boon on students of medical history by publishing it.

I am, Sir, yours faithfully,

Edinburgh, August 12th, 1929. G. MATHESON CULLEN.

NITRATE POISONING: AN EPITAPH.

WE are informed that the following appears on a tomb at Cross Kirk in Eshaness, Shetland.

> Donald Robertson, born Jan., 1783, died June 4th, 1848, aged 65. He was a peaceable quiet man, and to all appearance a sincere Christian and his death was very much regretted and was caused by the stupidity of Lawrence Tulloch in Closeheston (?) who sold him nitre instead of Epsom salts, by which he was killed in the space of five hours after taking a dose of it.

ENLARGEMENT OF HARROW HOSPITAL.—The district served by Harrow Hospital is increasing so rapidly in population that it has become urgently necessary to enlarge the institution. An extension to cost £22,500 has been prepared as part of a larger scheme which it is hoped eventually to carry out. There are at present 40 beds, but the enlargement will comprise wards for 18 additional beds and for 12 paying patients, an X ray department, a new operating block, and quarters for a resident medical officer. Nurses' quarters will be erected in the garden of the hospital. The extension is to be known as "The Stuart Memorial," in honour of the former president, the late Mr. J. N. Stuart.

Lettsomian Lectures

ON THE

RELATIONSHIP OF DERMATOLOGY TO OTHER BRANCHES OF MEDICINE.

Delivered before the Medical Society of London

BY H. W. BARBER, M.B. CAMB., F.R.C.P. LOND.,
PHYSICIAN IN CHARGE OF THE SKIN DEPARTMENT, GUY'S HOSPITAL

LECTURE I.

I HOPE to show in these lectures that Erasmus Wilson [1] was justified in his statement that "cutaneous medicine is a branch of general medicine of no insignificant importance," and for my part I hold very strongly the opinion that a study of the *normal* skin and accessible mucous membranes, and of the commoner changes that occur in them as a result of faulty metabolism, the action of physical and chemical irritants, and of external or endogenous invasion by infective organisms or toxic substances, should serve as the student's introduction to clinical medicine. For it is but logical that he should first be taught to see and interpret what he sees, and it is *in imparting this faculty of observation and deduction* that the dermatologist should find his chief métier in the early stages of a student's training.

PHYSIOLOGICAL FUNCTIONS OF THE SKIN.

It is the merest truism to say that the skin is the buffer between the body as a whole and its environment, and I will not waste time by enumerating its commonly accepted functions. There are, however, certain points in its physiology which are insufficiently realised, but are of profound importance in general medicine. As Ormsby [2] says: "The skin, in view of the number and mode of distribution of its nervous elements, may be regarded as a vast area of sensitive nerve-terminals." In virtue of this it determines to a great extent the reaction of the various organs of the body to external influences—heat, cold, light, and trauma. This it does owing to its close physiological connexion with the vegetative nervous system and the endocrine glands. It is not too much to say that it is through the medium of his skin that the evolution of civilised man has occurred, and for the following reasons.

The differentiation of the various species of animals and of the different types of mankind is in some degree a question of climatic conditions. As Cramer [3] points out, Man, in view of his comparative hairlessness, which handicaps his prevention of heat-loss, could only *have originated in a tropical climate*. But the constant damp heat of the torrid zone affords no stimulus to the endocrine-autonomic system, on the activity of which the maximal development of psychical and physical energy depends. Presumably civilisation dates from the time when a band of primitive men wandered northwards from the tropical zone, and, with the approach of winter, under the unfamiliar stimulus of cold to their naked skins, contrived to obtain artificial warmth, first, no doubt, by digging underground shelters, constructing huts, using the skins of animals as clothing, and later by discovering how to make fire. The action of cold on the skin was doubtless a most *potent stimulus to* Man's inventive faculties, and the means of protection that he gradually discovered made him more or less independent of climatic conditions. Having become so, however, his further development, the differentiation of races, and their subsequent rise or fall have depended on several factors, of which climate, with its local variations through the ages, has been, perhaps, the most important.

Ellsworth Huntington,[4] in his absorbing book "Climate and Civilisation," deals fully with this question. He illustrates in convincing fashion not only the broad effect of climate upon physical and mental activity, and consequently upon national characteristics, but also the influence of the weather at a given time on the degree of efficiency in work and on health. It would appear that "the same conditions of temperature, humidity, and variability which cause people to work quickly or slowly in the ordinary affairs of life seem also to cause their health to be good or poor."

I cannot here even briefly summarise Huntington's data or discuss his conclusions; for our purpose it is enough to emphasise the following points:—

(1) For work and health the best climate is one in which the mean temperature rarely falls below 38° F. or rises above 64°—i.e., an average of about 51° for the whole year.

(2) Apart from the mean temperature, variability of temperature and weather conditions from day to day are factors of great importance, as also is the relative humidity. Moderate changes of temperature are more stimulating than uniformity, a fall being preferable to a rise as regards human efficiency; a mean temperature of from 50° to 60° is the optimum for both physical and mental activities, which diminish rapidly above 65°.

(3) Localities, in which these conditions favourable to efficiency obtain, are exactly those in which human progress has reached its maximum, as may be seen at a glance in the *maps, illustrating the distribution of civilisation, health,* and energy, in Huntington's book.

Let those of us who are inclined to rail against our climate remember that it is largely responsible for the position in the world held by the Anglo-Saxon race to-day. It may not be the most agreeable, but, as Cramer says, *comfort does not make for human progress*.

Now it is clear that it is through the medium of the skin that the influence—stimulating or otherwise—of climatic conditions is exerted, and the significance and explanation of this influence upon human efficiency and health is afforded by Cramer's work on the thyroid-adrenal apparatus. Our sense of well-being, our initiative, and our resistance to many bacterial infections are dependent largely on our vegetative nervous system, which in turn is activated and regulated by endocrine glands, particularly the thyroid and adrenals.

Cramer has shown that heat-regulation is a function of this thyroid-adrenal-sympathetic system. The normal stimulus to this system is *the action of cold on the skin*, particularly the change from a warm to a cold environment. Under this stimulus the adrenals and the thyroid undergo striking histological changes indicative of intense activity; their capillaries dilate and into them are poured the active secretions—adrenalin and thyroxin respectively—which stimulate the sympathetic throughout the body. As a result the cutaneous vessels are constricted to diminish heat-loss, and this constriction, if intense enough, inhibits sweat secretion; the voluntary muscles, the chemical *activity of which, according to Orbeli,*[5] is under the control of the sympathetic, are stimulated, voluntary muscular exercise or involuntary movement—i.e., shivering—being the response to such stimulation; and the liver secretes more glucose into the blood stream, in order to provide the muscles with more fuel, the consumption of which increases heat-production, thus creating a rise in the metabolic rate.

On the other hand, in an animal or person at rest, in a warm even atmosphere, the alveoli of the thyroid remain full of colloid, many of the capillaries surrounding them, which are dilated when the gland is actively secreting, are invisible, and the cells of the adrenal *medulla* are fully charged with adrenalin. Metabolism is quiescent, the demand of the tissues for glucose is minimal, and excess *of food is deposited as fat.* Long-continued exposure to cold will, of course, in time lead to exhaustion of the adrenals and thyroid, and deplete the liver of glycogen; heat-regulation, therefore, fails, there is great heat-loss without a compensatory *heat-production, and death results.*

It is thus easy to understand the virtue of a temperate climate, with its frequent but moderate changes from warmth to cold and vice versa, since such changes tend to keep the thyroid-adrenal-sympathetic apparatus in a state of maximal efficiency, making for vigour of body and mind; on the other hand, the relaxing effect of the constant moist heat of the tropics, which induces physical and mental indolence, and the paralysing influence of long periods of intense cold are likewise explicable.

Here the personal factor comes into consideration. In the struggle for supremacy between the races, both in warfare and in industrial competition, the weakling is of no account, and is merely a drain on his country's resources; it is a question of the *average* standard of physique, mentality, and initiative. We, as doctors, however, have to consider the weakling, and we are all too familiar with the type for whom our climate is the reverse of stimulating. There are many whose endocrine-sympathetic system is unable adequately to respond to the stimulus of cold, and are only happy in warm surroundings. One such type is provided by the thin, hypotonic, ichthyotic person, in whom asthma and its associated symptoms are so common, and who spends his winter shivering and snuffling over the fire. It has long been recognised that these persons present symptoms indicative of thyroid-adrenal insufficiency. Another type which cannot adapt itself to cold weather is represented by the acro-asphyxial girl, who, since the vogue of short skirts, has crowded our out-patient departments in winter on account of a passive erythema, often accompanied by actual œdema and chilblains, involving the lower parts of the legs and ankles. This condition—christened "erythrocyanosis crurum puellaris"—has received a good deal of attention of late, both in this country and abroad. That it depends on a lack of tone of the capillaries in the skin would seem certain, and the general appearance of those in whom it occurs suggests an endocrine insufficiency. In view of its incidence almost exclusively in females, and the frequency of amenorrhœa or menstrual irregularity, one would suspect a disorder of normal ovarian, and perhaps thyroid and pituitary function. These two types, at any rate, if compelled to live a sedentary life, are ill-adapted to a cold or even temperate climate; they both feel and work better in moderately warm countries with abundance of sunlight.

Although, however, the invention of clothing and artificial methods of heat-production have enabled Man to flourish in climates which favour his activities and progress, leading thus to the evolution of our present complex civilisation, yet, owing to the misuse of the very comforts, pleasures, and labour-saving devices that his own ingenuity has created, and to the unnatural conditions under which a large proportion of a civilised population lives, the effect on his purely animal functions has been disastrous. On the one hand we have the self-indulgence in excess of food and drink, and the slothful physical ease, engendered by wealth, which result in the metabolic diseases of plethora, so common among the richer classes; on the other, the diseases of under-nutrition, faulty diet, insufficient sunlight and vitiated air, predisposing to serious infections, such as tuberculosis and rheumatism, that ravage the poor.

A wise Frenchman has said: "L'homme ne meurt pas, il se tue"; he has created his own pathology, and it is a sobering reflection for us, as medical men, that we spend our lives trying to cope with morbid conditions that are for the most part of Man's own making. The study of metabolic functions gone wrong, or of the multitude of infections engendered by civilisation, and the elaborate methods of treatment by drugs, vaccines, sera, and so forth, though of absorbing interest, must nevertheless to the abstract philosopher, appear pathetically humorous.

To anyone who surveys the general trend of medical research and treatment during the past few years it must be obvious that we are getting back to where we started from. While admitting that Man's progress is partly dependent on his control of tem[illegible] by clothing and fuel, when he begins to [illegible] [illegible]ty we strip him and expose his naked [illegible] sun and air, its [illegible] [illegible]lium, or, le[illegible] [illegible]ly, to artificial [illegible] [illegible] we stimu[illegible] functions by hydrotherapy; and, while voting for politicians who solemnly budget for cheap foods of a kind that are precisely the least valuable, or actually harmful, and while admiring the ingenuity of the Chicago meat-packer or the tinned-fruit exporter, we advise our patients to avoid their goods, and eat chiefly the fresh produce of the vegetable garden, orchard, and dairy farm. Although the ancient Egyptians, Greeks, and Romans were all apparently cognisant of the beneficial action of sunlight and cool air on the skin, and of physical exercises, modern civilised peoples have only recently rediscovered this, together with the essential qualities of certain natural foods. The very factors which enabled man to emerge from his tropical lassitude have for generations militated against his physical development and health. Clothing and fuel, which are essential for him if he is to withstand the rigours of winter, he has abused, covering his unfortunate skin, even in summer, with layer after layer of thick impermeable material, and heating his houses, hotels, and public places to such a degree that he creates an atmosphere even more pernicious than that of the torrid zone from which he sprang.

The evil effects of overheated rooms, both on physical energy and on resistance to microbial infection, have been amply demonstrated by the experiments of the New York State Ventilation Commission (quoted by Huntington[4]). This Commission found that even slight overheating (75° F.) throws a burden on the heat-regulating system of the body, there being a marked *decrease in general vasomotor tone*, with an abnormal reaction of the mucous membrane of the nose, leading ultimately to chronic atrophic rhinitis, and, when followed by chill, producing a moist and distended condition of the membranes, calculated to favour bacterial invasion. In animals, exposure to high atmospheric temperatures, particularly when followed by chill, diminishes the protective power of the blood and markedly increases general susceptibility to microbic disease. Similarly, with regard to clothing, the arbitrary dictates of modesty and fashion and the mistaken fear of "catching cold" have robbed the body of one of its chief metabolic regulating mechanisms, and most important defences against infection—namely, the exposure of the skin to light and air.

I have said that civilised man has created his own pathology, but this statement requires some amplification. One can, I think, reasonably compare the diseases to which Man, living an active outdoor life under so-called primitive conditions, is subject, to those of animals in their natural wild state; and similarly those of Man under so-called civilised conditions with those of animals in captivity. In the former case both Man and wild animals are liable to invasion by parasites, conveyed, for example, by biting insects, or in water or food; in the latter case, however, the unnatural conditions have created certain disorders of metabolism and function, which were probably unknown amongst primitive peoples and do not occur in wild animals, and infection with a number of banal and incompletely differentiated organisms that were originally harmless saprophytes, but which have become pathogenic, partly owing to the favourable environment afforded by such metabolic and functional disorders, and partly to the facilities for transference and persistence that overcrowding and other factors supply.

Even in the memory of our generation the kaleidoscope of disease, viewed as a whole, has changed, as Horder[5] illustrated very clearly some years ago in his paper on New Diseases for Old. Briefly stated, the more virulent infections are being succeeded by a variety of subacute or chronic conditions due, as I have said, to organisms that were formerly considered non-pathogenic, and normal habitants of our mucous membranes.

Now I wish to illustrate these remarks in the following way. The skin and the mucous membranes of the mouth, nasopharynx, and intestines have a natural *saprophytic* flora of their own; they may all be invaded and actively infected by organisms foreign to them with the production of well-defined and specific diseases, but their own common saprophytes may under certain conditions become themselves pathogenic, giving rise both to local lesions, and, by invading the blood stream or elaborating absorbable toxins, causing morbid effects in distant organs or tissues.

In a paper I read before the Odontological Section of the Royal Society of Medicine in 1927 [7] I said :—

> "It is clear that in dealing with the question of actual infection with these common saprophytic but potentially parasitic bacteria we have to consider, first, their active growth in the host's tissues, and, secondly, the immediate and remote results of such active infection. The first part of the question is clearly biochemical or metabolic in nature; what, in fact, are the changes that take place in the host that render him a suitable culture-medium for organisms which he normally harbours only as saprophytes? The second part of the question is concerned with the local pathological changes produced by bacterial invasion, and with the possible systemic effects that may arise from it in parts of the body remote from the original site of invasion; in other words, focal sepsis and its results."

EXTERNAL INFECTIONS OF THE SKIN.

The skin is liable to invasion from without by parasitic organisms varying from insects to filtrable viruses. Now it might be thought that in the genesis of these external infections the influence of internal factors hardly comes into play. Nothing is farther from the truth, yet this view was largely held by one German school of dermatologists, which threw scorn on the terms "diathesis" or "soil" so often employed, particularly by the opposing French school. To cite an oft-quoted example, the common ringworm infection of the child's scalp dies out at puberty, and, except in the rarest instances, is never seen on the adult scalp. Why? Not, I think, owing to the development of a general immunity, for as Adamson [8] points out, the ordinary microsporon of scalp ringworm grows in the horny tissues, and excites, as a rule, little or no inflammatory response; but presumably because some change occurs in the horny layer or possibly the sebum of the scalp at puberty, which is inimical to the growth of the fungus, and such a change must be primarily of internal origin.

When we come to consider the common saprophytes of the skin this influence of internal factors is still more apparent. Contrary to popular belief, normal clean skin is remarkably amicrobial. The intact healthy horny layer, although it may harbour organisms on its surface, is never penetrated; only in the mouths of the pilosebaceous follicles does one see a few cocci, lying as Sabouraud [9] insists, as isolated units and not in a state of active growth. Normal sebum is composed of various neutral fats, mixed with fatty acids, which are in combination, not with the tribasic alcohol glycerol, but with the monatomic alcohol cholesterol. These *cholesterol fats* are not easily decomposed by bacterial growth, and are not a suitable culture medium. I repeat that in absolutely normal skin there is no active bacterial growth; on the other hand, in the most trivial infective lesions one finds an astonishing number of organisms, and it is fairly safe to say with Sabouraud and Whitfield [10] that "when an organism is found in a state of active growth upon the skin it is exciting its noxious effect if it has any."

When we survey the list of organisms that may infect the skin we can pick out three that are so commonly present that they may be considered as normal habitants, at any rate in civilised man; they are: the pityrosporon of Malassez, the micro-bacillus of acne, and the *Staphylococcus albus*. Nevertheless, the skin of a normal person in perfect health will show no evidence of active infection with these organisms. I make this statement dogmatically, knowing that, since some degree of such infection is so common, it may be disputed; it is a question of the normal standard.

The active growth of the three organisms named above is predisposed to by that morbid state of the skin which is usually termed *seborrhœa*, by which is meant an excessive and altered secretion of the sebaceous glands; but seborrhœa is only one symptom of the complex that has been variously termed "la kérose" by Darier, the "status seborrhoeicus" by Montgomery, Semon, and myself, and the "seborrhœic diathesis" by Scholtz. I do not mean to imply that these organisms only grow in seborrhœic skins, but seborrhœa is by far the commonest predisposing factor to such growth.

The term "diathesis" employed by the old clinical physicians to designate a predisposition to certain symptom-complexes, which they clearly recognised but could not explain, almost withered before the storm of more accurate knowledge acquired from a study of post-mortem pathology and bacteriology. Sabouraud, to whom we owe so much of our knowledge of external infections of the skin, has himself made some very scathing comments upon it, but we are now returning to the conception of diathesis, because biochemistry suggests and will doubtless confirm its accuracy. Of all diatheses the seborrhœic one is probably the commonest, and for this reason, perhaps, it has been practically ignored in the past by general physicians, who, obsessed by the symptoms and signs of what is called "organic disease," have neglected the tell-tale surface markings of faulty metabolism. The importance of the seborrhœic state in my present thesis is that it exemplifies how a metabolic change resulting from unnatural conditions of life may produce an environment which enables harmless saprophytes to become parasites and produce "skin diseases"; it enables us to study the local defensive reactions of the skin against these several organisms, the underlying factors which predispose to the change from saprophytism to parasitism, and the means of preventing or counteracting this change. As we shall see, however, the skin is not involved alone in the seborrhœic state; the mucous membranes suffer too, and become likewise a prey to their particular saprophytes.

THE SEBORRHŒIC TRIAD OF ORGANISMS.

It is necessary to say a word about the triad of organisms that inhabit the skin, but I shall avoid irrelevant detail.

The Pityrosporon of Malassez.

First discovered by Malassez in 1874 this organism was, so to speak, rediscovered by Unna and named by him "Flaschen-bacillen," and since then has been commonly known as the "bottle-bacillus," an unfortunate name since it is not a bacillus. Sabouraud[11] insisted on its constant presence in a state of active growth in the horny scales of the true pityriasis simplex of Willan—the familiar "scurf" or "dandruff," and he pointed out that it grows exactly in the same way between the superficial layers of the stratum corneum as does the *Microsporon furfur* of *pityriasis or tinea* versicolor, which, although like the pityrosporon of Malassez, had at that time never been cultivated artificially, was nevertheless universally accepted as the causal organism of this condition.

Sabouraud's arguments that the pityrosporon of Malassez must be the cause of simple dry scurf were accepted by most dermatologists, and until recently it has been generally held that the definitely inflammatory group of eruptions, known variously as seborrhœic dermatitis or eczema, seborrhœides, eczématides (Darier), of which the so-called "flannel rash" of Blackfriars Hospital is, perhaps, the best defined, was due to infection with the pityrosporon of Malassez and a *Staphylococcus albus* (the polymorphic coccus of Cedercreutz), growing in symbiosis. The difficulty of determining this point experimentally was largely due to failure to cultivate the pityrosporon; inoculation of the skin with cultures of the above staphylococcus produced merely small superficial follicular pustules.

Sabouraud attempted to grow the pityrosporon on a number of media without success; Whitfield[12] obtained it once in impure culture, but lost it in attempting subcultures; Templeton,[13] in 1926, announced that he had cultured it anaerobically, but the growth was poor. As long ago as 1908, however, W. G. Garner succeeded in growing it on maltose agar and acid glycerine agar, but his achievement was neglected, until quite recently MacLeod and Dowling[14] not only determined its cultural reactions, but also performed some very important inoculation experiments with it.

The organism is one of the fungi imperfecti and belongs to the class Oösporaceæ. It is nearly related to monilia, but differs from it in certain respects; for example, the pityrosporon forms no mycelium in solid media, but mycelial threads are abundant in fluid media, whereas the monilia produces scanty thick mycelium on solid but none on fluid media. By inoculation of cultures of the organism MacLeod and Dowling were able to produce typical figurate seborrhœic dermatitis, indistinguishable both in evolution and appearances from the natural eruption. *Inoculation on normal non-seborrhœic skins* produced a group of follicular papules within 24 hours, which lasted about ten days and then disappeared; in some seborrhœic subjects, particularly those with active seborrhœic dermatitis present, a more acute reaction developed, and a widespread figurate patch sometimes resulted.

It is thus clear that seborrhœic dermatitis, like simple dandruff, is a pure fungus infection due to the pityrosporon; the degree of inflammation produced by the organism appears to depend partly on the site infected, the scalp, though the commonest, being as a rule more resistant than the glabrous skin, and partly on the constitution and habits of the host.

The Acne Bacillus.

First described by Unna and Hodara[15] as the acne bacillus, and later by Sabouraud[16] as the microbacillus of seborrhœa, this organism has been the subject of considerable discussion, particularly as regards its exact rôle in the genesis of simple seborrhœa and of the polymorphic eruption, acne vulgaris. It would be irrelevant to deal with this discussion here, but the following points should be noted: (1) The acne bacillus grows in the infundibulum or upper third of the pilosebaceous follicle—i.e., the part lying between the opening of the sebaceous gland and the mouth of the follicle. In this portion, as Sabouraud[17] emphasises, there is a virtual space between the epithelial lining of the follicle and the hair, occupied by sebum and horny débris. (2) If the so-called "seborrhœic cocoon" be expressed from the pilosebaceous follicle of a seborrhœic person, squeezed flat on a slide, and suitably stained, myriads of acne bacilli will be seen obviously in a state of active growth. (3) As a result of infection of the follicles with this organism there may arise in certain situations the polymorphic lesions of the common acne juvenilis—comedones or "blackheads," acne papules, pustules, &c. Sabouraud, I think rightly, maintains that the true acne pustule is due to the acne bacillus, and not to a secondary invasion with a *Staphylococcus albus*, although staphylococcal lesions may be and often are present in acne. This view has been recently confirmed by Goldsmith's[18] work on the staphylococci in acne vulgaris.

The Staphylococci.

The *Staphylococcus pyogenes aureus* is not a normal habitant of the skin, a fact that is often not appreciated. Both Goldsmith and Ferguson Smith[19] have confirmed this, but once an active infection with this organism occurs, it is, so to speak, "sown" in the mouths of the pilosebaceous follicles, not only in the neighbourhood of the active lesions, but also in parts of the skin widely distant from them, and the patient becomes a "pyococcus-carrier"; the danger of such a carrier in connexion, for example, with epidemics of pemphigus neonatorum, is clearly shown by the recent work of Benians and Jones.[20]

With regard to the *Staphylococcus albus*, it is useless, I think, to attempt to differentiate the various strains that have been described. Cedercreutz[21] considers that all these are but modifications of the same organism, and, as Benians[22] says, "the habits of the *Staphylococcus albus* in its various forms seem to be anything from those of a harmless saprophyte to those of a definitely pyogenic organism. Culturally, it appears to vary from a greyish and translucent to one of a brilliant enamel white colour." Suffice it to say that the *Staphylococcus albus is* a normal habitant of the skin—saprophytic but potentially parasitic, like the pityrosporon and the acne bacillus. The natural position in the skin for staphylococci is the mouth of the pilosebaceous follicle, and for the most part staphylococcal lesions are primarily follicular.

Habitat of these Organisms.

The three organisms that I have just briefly described may be regarded as the normal flora of the human skin, at any rate under civilised conditions. Each has its own localisation or site of election in the skin, and each, as Sabouraud and Adamson have *pointed out, when it takes on active growth, excites* a special type of cell-response to invasion.

Thus the pityrosporon, like a ringworm fungus—e.g., the *Microsporon furfur*, grows in between the layers of the stratum corneum, which hypertrophies, and is shed in visible flakes or pellicules ("dandruff" or "scurf"), such exfoliation, no doubt, being an attempt to cast off the parasite; on the scalp and other hairy parts, the pityrosporon, like certain ringworm fungi, may excite little or no inflammatory response in the cutis, but on the glabrous skin both it and a ringworm fungus provoke definite clinical and histological signs of inflammation.

The acne bacillus flourishes in myriads in the infundibular portion of the pilosebaceous follicles, and there may, like the pityrosporon, provoke both a non-inflammatory and inflammatory defence-reaction—viz., the comedo and the acne pustule. The comedo is a cocoon-like body composed of concentric layers of horny cells, which enclose a mass of the bacilli and inspissated sebum; as Adamson says, it may be looked upon as a reaction upon the part of the horny cells to the invasion of the follicle by the acne bacillus, or, as Whitfield[23] puts it, the epithelium endeavours to deal with the bacillus in the way in which the epidermis always deals with foreign bodies—namely, by encysting it with horny cells. The true acne pustule represents the inflammatory defence-reaction to the bacillus, although it has commonly been held to result from secondary infection with a *Staphylococcus albus*. Sabouraud[24] has clearly shown that the acne bacillus alone is responsible, and he points out that the leucocytic reaction is denser than in staphylococcal infection, producing thick caseous pus, unlike the fluid creamy "laudable pus" of the latter.

Staphylococci are normally present in clean healthy skin at the ostium of the pilosebaceous follicle as isolated units, waiting their opportunity to germinate, multiply, and produce active inflammatory lesions, the simplest of which is a small pustule formed at the mouth of the follicle and surrounding the hair. The normal defence to staphylococcal infection is the polymorphonuclear leucocyte. I cannot here describe the different types of staphylococcal lesion in the skin; they have recently been dealt with by

Organism.	Habitat.	Defence-reaction.	Lesion.
Pityrosporon.	Stratum corneum.	Exfoliation of horny cells. Cuticular inflammation.	Pellicle or dandruff. Seborrhœide or seborrhœic dermatitis.
Acne bacillus.	Infundibulum of pilosebaceous follicle.	Proliferation of horny cells to enclose it. Dense leucocytic exudation.	Comedo. Acne pustule.
Staphylococcus.	Ostium of follicle.	Polymorphonuclear exudation.	Pustule. Boil. Sycosis, &c.

Sabouraud.[15] The essential points are that the natural habitat for staphylococci is the mouth of the follicle, that the majority of staphylococcal lesions are follicular, and that the formation of pus from polynuclear leucocytes is characteristic.

I may summarise what I have just said in the Table above.

THE SYMPTOMATOLOGY OF THE SEBORRHŒIC STATE.

Some *degree of seborrhœa and slight active infection* with its triad of organisms are so commonly seen that the entirely non-seborrhœic person, who remains so throughout life, would seem to be exceptional. It will be understood that in the following description I am referring to those in whom seborrhœic manifestations are severe enough to be noticeable, and, as a rule, to demand treatment. Now I think that clinically one can conveniently classify these persons into two types: to one belong the flushed, robust, active, and in later life plethoric sort; I call this the pure or simple seborrhœic type: to the other belong the pallid, thick-skinned, pigmented, hypotonic kind. The former are usually fair, the latter dark or mouse-coloured, but not necessarily so. There are certain differences, as regards their seborrhœic manifestations, between these two groups, and often, I believe, the chief underlying factors predisposing to their seborrhœa are not the same in the two cases.

I will now briefly summarise the symptoms of the seborrhœic state:—

Cutaneous Manifestations.

The normal skin, as exemplified by that of the perfectly trained athlete, or as seen in those who have undergone the "sun and air cure," is beautifully smooth, supple, and clear; the horny layer is thin and translucent, and is cast off in invisible flakes, the pilosebaceous orifices are hardly visible, and the secretion of sebum and sweat (except in heat, strong sunlight, and after exercise) is imperceptible; the hair is sleek but not greasy, and there is no evidence whatever in the skin of active bacterial growth.

Contrast this with the skin of the seborrhœic person; as a whole, it appears thickened, coarse, and dirty, particularly in dark-complexioned persons; the horny layer is improperly formed and hypertrophied; the pilosebaceous orifices are enlarged and patulous, and either exude visible droplets of oily sebum, or are filled with solid plugs—the so-called seborrhœic cocoons—containing countless acne bacilli; there is often visible hyperidrosis in certain situations; the scalp after puberty is greasy, covered with adherent dandruff, which swarms with the pityrosporon and the *Staphylococcus albus*, and the hair dank and lifeless. To this picture must be added the infective complications—the comedones, pustules, and nodules of acne, the various *forms of* seborrhœic dermatitis, the superficial pustules due to the *Staphylococcus albus*, the deeper folliculitis of sycosis and boils due to the *Staphylococcus aureus*. In middle life rosacea, which sooner or later becomes complicated by a superadded infection of the flushed area with the seborrhœic organisms, is common.

Mucous Membranes.

Mouth.—The appearances of the mucous membrane of the lips, mouth, and tongue vary according to the type of seborrhœic person. In the simple type the vermilion borders of *the lips* are usually bright red, and covered with a yellowish, superficial crust, which I call the "seborrhœic scum"; *the tongue* is firm and red, and the papillæ prominent; *gingivitis*, representing doubtless the same lowered resistance to infection that characterises the skin is common, and the earlier the onset of the seborrhœic state, the sooner does it occur. In the other type of seborrhœic person, the lips may be pale or bluish, the tongue pale and indented, and its papillæ hardly visible.

The Teeth.—Dental caries and simple gingivitis are, I consider, the rule, at any rate in the simple seborrhœic; on the other hand, true pyorrhœa alveolaris is not.

Nasopharynx.—Chronic nasopharyngeal catarrh, with frequent exacerbations, is almost invariably present in severe cases of the seborrhœic state. It was a striking symptom among those met with in France during the war. In chronic seborrhœics, with symptoms dating from childhood, this catarrh is usually associated with the adenoid facies and marked hypertrophy of the lymphoid tissue; on the other hand, *it may develop as an entirely new symptom* in conjunction with infection of the skin, in those who become seborrhœic as a result of adopting a sedentary existence in middle life.

The Digestive System.

Symptoms referable to disorders of the digestive system differ so widely in the two types of seborrhœic, that a detailed discussion of their significance would be futile. Genuine intestinal flatulence, distinct from aerophagy, is a common sympton, due, I believe, to fermentation of carbohydrate, since it is almost *always relieved by exclusion of soft carbohydrate* foods from the dietary. Observations on the secretion of HCl by the stomach are, so far as I am aware numerous only in cases of rosacea. Ryle and I[16] investigated a small number of patients—all women—and found complete or extreme hypochlorhydria in 58 per cent. In Brown's[17] 50 cases, the percentage was lower—30 per cent.—and Eastwood[18] found a low secretory curve in about half her cases. My impression is that in the simple type of seborrhœic, the gastric HCl is usually normal or excessive, whereas in the other type it is usually diminished.

The Urine.

Sabouraud[19] in 1902 stated that an examination of the urine of 83 men with actively progressing seborrhœic alopecia, but in apparent good health, showed three characteristics—hyperacidity, excess of chloride, and diminution of phosphate. During the war, while working with Semon on large numbers of cases with active seborrhœic infections, I was impressed by the apparently high urinary acidity.[20] In most cases large and in some enormous doses of alkali were required to render the urine alkaline. We were also struck by the beneficial effect of alkalis in large doses in the more acute cases. We expressed the opinion that the character of the military rations and the unavoidable lack of fresh fruit and vegetables were probably in part responsible both for this high urinary acidity, and for the prevalence of seborrhœic manifestations among the troops. The same increased acidity of the urine is also found among civilian patients with acute symptoms of the seborrhœic state, and I believe that a close inquiry along modern lines into this question provides a promising field for biochemical research. One interesting fact is that in certain cases the administration of alkali causes the urine for a while to become progressively more acid.

THE ÆTIOLOGY OF THE SEBORRHŒIC STATE.

In considering the ætiology of the seborrhœic state it must be insisted that an apparently excessive secretion of sebum does not necessarily constitute seborrhœa in the pathological sense. It is probable, as Whitfield[21] suggests, that the greasy skin of the healthy negro is a physiological protective response to intense sunlight. The secretion of sebum, like that of sweat, saliva, and tears, is under the control of the *autonomic nervous system. Whitfield has remarked on* the reflex localised seborrhœa of the forehead resulting from eyestrain, and a similar local secretion of sebum and sweat may be provoked by electrical stimulation of the skin, as is sometimes seen in the treatment of facial blemishes by electrolysis. Of greater interest is the seborrhœic facies that may be met with in *encephalitis lethargica.* This was noted by Colin[22] and Sarbo[23] in early or acute cases, and Krestin described it as a feature of chronic cases manifesting the Parkinsonian syndrome; it was commonly associated with sialorrhœa and occasionally with rhinorrhœa. Krestin[34] also noted it, sometimes with sialorrhœa, in cases of senile paralysis agitans. The explanation would seem to be that "these secretory disturbances may depend upon lesions in the neighbourhood of the third ventricle involving vegetative nerve centres."

When we come to consider the factors responsible for the seborrhœic state, as ordinarily met with, we are at once struck by their complexity, but, lest I confuse the issue by attempting to present a comprehensive survey, I would at the outset emphasise what I believe to be the real crux of the problem.

The skin is intimately concerned with fat metabolism. It lies in close contact with the chief fat depôt of the body, its horny layer is permeated with fat, and the sebaceous glands and even the sweat glands secrete it. I find myself in agreement with Darier,[35] Montgomery,[36] and Scholtz,[37] who hold that *the essential and obvious change in the seborrhœic state is an alteration in the secretion and composition of the cutaneous fat*, and it is clearly this modification that favours the parasitic growth of the saprophytes of the skin. When all the minor factors—heredity, age, sexual evolution, &c.—are considered, this one fundamental cause remains predominant. That some similar biochemical change occurs also in mucous membranes would seem probable, in view of their comparable lowered resistance to invasion by saprophytic organisms.

The Influence of Diet and Personal Hygiene.

If we agree that the seborrhœic state is an index of faulty metabolism as regards fat and fat-forming foods, it becomes evident that diet, or rather the correlation between diet and the expenditure of physical energy, is a factor of paramount importance. Granted that there is an inborn and often hereditary tendency to seborrhœic manifestations, nevertheless I believe that all of us are potential seborrhœics. This is suggested by the fact that those, who in their youth have lived athletic outdoor lives, often develop seborrhœa and its complications for the first time when they abandon their games, adopt a sedentary occupation, but continue to eat as much, perhaps more, than previously. The relationship of diet to seborrhœa has been well analysed by Montgomery; he considers in detail the various foodstuffs—sugars, starches, fats, and alcohol—excess of which is a potent predisposing factor. The question is complicated by the fact that excess is not the whole story; the rate of absorption, and probably the liability of certain foods to undergo bacterial fermentation, with fatty acid production, also come into play. Our knowledge, however, of the metabolism in the seborrhœic state is fragmentary and based almost entirely on clinical observations, some of which, it is true, are definite and constant enough to allow of conclusions being drawn, but a complete biochemical investigation of the whole problem is urgently needed, and would, I believe, throw light on much that is now obscure.

Fats.

Our knowledge of the influence of fats on seborrhœa is fairly precise. Kossmann, de Jong, Plate and Röhrmann, Buschke and Fränkel, have all shown that sometimes the sebaceous secretion may have the same chemical characteristics as the fat ingested. The experiments of Policard and Mlle. Tritchovitch[38] explain this and are of great interest.

They are based on the observation of Daddi that sudan-red and scarlet-red, if given with the food by mouth, produce vital staining of depôt fat and adipose tissue. Policard and Tritchovitch showed, however, that only the depôt fat is thus coloured—for example, that of the subcutaneous tissue and omentum, the composition of which depends very largely on that of the fat ingested. On the other hand, the essential fat of the various organs is not stained; in the normal liver, for example, there is found no trace of the dye. If the animal is starved the coloured fat disappears and with it the colouring matter.

These authors then showed that normally the cells of the sebaceous glands elaborate their fatty secretion from the fatty acids circulating in the blood; this, as Regaud and Favre have shown, is a process of true cellular activity. On the other hand, they are capable of fixing directly fatty particles that circulate in the blood, especially after digestion. This fat, unlike the normal sebaceous secretion, is coloured after ingestion of scarlet-red; it is only seen in the large "obese" glands of fat animals, never in normal glands. The fat of fixation is found extending to the periphery of the gland in close contact with the capillaries; the normal sebaceous fat is localised to the centre of the gland near the excretory part. It is thus seen that the normal function of the sebaceous glands is adipogenesis, the manufactured fat having a special composition of its own; under certain conditions—in animals after hyperalimentation, for example—they take on the function of adipopexy, in which case the fat taken up directly from the blood may have the characters of that ingested.

From these observations it is easy to understand how the normal sebaceous secretion may be altered either by the excessive intake of fat or fat-forming foods, or by the ingestion of special forms of fat. As I have said, the normal cholesterol fat of sebum is inimical to bacterial growth; but other fats are not, and it is doubtless when the composition of the sebum is changed by the adipopexic function of the sebaceous glands, that the active growth of the saprophytes of the skin are encouraged. This would explain the contention of Kenneth Wills that some cases of acne will yield to the omission of pig-fat from the dietary, and the observations of Whitfield that in some patients cheese will invariably provoke an outbreak of this eruption. As Montgomery points out, milk-fat is particularly liable to bacterial decomposition, hence the danger in seborrhœics of excess of cream or milk.

Apart from fats there is general agreement that excess of carbohydrate aggravates existing seborrhœic manifestations; a girl's complexion may be an index of the number of chocolates she has consumed the previous evening. It would seem that concentrated sweetstuffs and soft starchy foods, which cannot be properly masticated, particularly if cooked with milk, tend to ferment with the production of fatty acids and gas. Sabouraud[39] has emphasised the astonishing effect of merely excluding bread from the dietary of fat seborrhœic people, many of whom consume it mechanically in large quantities at meals which are otherwise adequate or excessive.

Alcohol.

That excess of alcohol promotes seborrhœa is a fact that he who frequents bars can see, but its mode of action is probably complex. It is a vasodilator, and through the ages has been recognised as a common cause of true rosacea, which is always accompanied by seborrhœa. I know no more striking clinical experiment than to observe the change that occurs in the complexion of a chronic alcoholic when he is persuaded or compelled to become a teetotaller. Apart from its vasodilator action alcohol is a carbohydrate and fat sparer, since it is so readily oxidised.

It is clear that the influence of diet in seborrhœa must be considered in relation to the mode of life. It is a question of oxidation. The best treatment for the seborrhœic state, apart from dietary restrictions, is a vigorous outdoor life with light clothing in a bracing sunny climate; it is the only one, in fact, that I have found of permanent benefit. Muscular exercise and deep breathing by which complete oxidation is ensured, the action of cool air in stimulating the thyroid-adrenal-sympathetic system, and thereby the metabolic rate, and the direct and indirect influence of sunlight on the skin—these are the important preventive measures. On the other hand, a sedentary life in overheated rooms, a dietary grossly disproportionate to the muscular energy expended, indulgence in alcohol, excessive clothing, and lack of personal cleanliness, are the chief predisposing factors.

In conclusion, the adjuvant factors may be briefly reviewed.

Heredity and Predisposition.

That there may be a hereditary and congenital predisposition to the seborrhœic state is, I think, beyond question. Seborrhœic families are common enough, and conversely certain families appear to be almost immune. I believe heredity to be an important *factor in the so-called seborrhœic alopecia*—the common baldness of men, or calvities.

Scholtz defines the seborrhœic diathesis as a congenital or hereditary tendency to present certain clinical skin manifestations *under the influence of* certain dietetic and metabolic factors, and it is unquestionably true that of two persons on approximately the same diet and living under the same conditions the one may become seborrhœic and the other not. At the same time the influence of environment and habits must be borne in mind when estimating the rôle of heredity and predisposition. Parents are apt to apply the same principles of diet and hygiene that their parents applied to them in bringing up their children. The Jews as a race are notoriously liable to seborrhœic manifestations and to diabetes; to what extent this tendency is hereditary or is dependent on their love of fatty and sweet foodstuffs, combined with a disinclination for physical exercise, is difficult to estimate.

Age and Sexual Evolution.

The various manifestations of the seborrhœic state follow in their evolution much the same stages as depicted in Shakespeare's seven ages of man. In infancy the true milk-crust betrays the future seborrhœic; the inevitable infection of its scalp from the parents or nurse with the pityrosporon takes root, and may cause the seborrhœic variety of infantile eczema. This infection persists as dry dandruff of the scalp till puberty, at which time the sebaceous glands awaken into activity. The scalp becomes greasy and covered with the so-called pityriasis steatoides; the micro-bacillus flourishes and gradually produces juvenile acne, which continues until the age of 25 or longer, and is often associated *with or succeeded by seborrhœic dermatitis.* At 18 or later begins calvities, which follows its relentless course, delayed, perhaps, but never arrested. In the third or fourth decade comes rosacea, and with it the so-called seborrhœic warts, which persist till death. These last, regarded by Darier as late nævi, must be distinguished from the true senile keratoses, picturesquely labelled by the French "fleurs de cimetière," thus implying their tendency to cancerous degeneration.

The Sexual Glands.

It is obvious that the evolution of the various complications of the seborrhœic state is closely connected with that of the sexual organs. The influence of puberty, of menstruation, and of the menopause can clearly be recognised.

The *growth of the hair and the activity of the* sebaceous glands are intimately related, and on the scalp the greater the latter, the less the former. That this relationship is connected with the endocrine glands concerned in sexual differentiation is certain, but its significance is obscure. Virility tends to loss of hair on the scalp with its increased luxuriance on the beard and body; feminism to a converse distribution. Sabouraud,[40] who has written so entertainingly on this subject, points out that the old satyrs are always depicted as bald on the head and hairy on the body, and the association of baldness, a large beard, and a hairy body was a common one when beards were the fashion. On the other hand, as Sabouraud's researches by proxy in the harems of the East reveal, a eunuch never develops the male type of baldness.

This influence of sex was illustrated in startling fashion by a case of suprarenal tumour in a female patient, which I had the opportunity of observing. There was the usual growth of beard and moustache, and cessation of menstruation, together with loss of hair on the scalp exactly resembling the ordinary male type of baldness. On removal of the tumour, normal menstruation began again, the hair on the face fell off, and a complete regrowth of that on the scalp took place. Unfortunately, recurrence of the malignant tumour was later apparent, and the former symptoms of virilism returned before death.

Intestinal Toxæmia.

I hesitate to employ this term—so simple in application, so difficult to define accurately. At the same time, as I have said, there is a type of seborrhœic person that for want of a better epithet I have labelled the "toxic" type, whose appearance is in marked contrast to that of the flushed, vigorous, "simple" seborrhœic. He is sallow and pigmented, his muscles are hypotonic, his tongue is flabby and furred, his breath foul, and the smell of his skin differs from that of the simple type. Invariably, I think, one finds a large quantity of indican in his urine, and not uncommonly a striking excess of urobilin. He improves out of all knowledge on a diet consisting largely of vegetables, fruits, crisp cereals, nuts, &c., simple laxatives such as rhubarb, and a vigorous out of door life. One girl, belonging to this type, of my acquaintance—a very severe and intractable case of acne—cured herself quickly by joining some cult which enjoins a diet as above, colon wash-outs, and regular breathing exercises.

One has to remember, however, that, as Hurst[41] pointed out long ago, many of the signs and symptoms of so-called intestinal toxæmia are the result of mechanical distension of the rectum by fæcal accumulations, and are at once relieved when these are removed. The well-known experiments of Donaldson[42] on healthy men, I think, prove this conclusively. He showed that deliberate abstention from defæcation for four days, or packing the rectum with cotton, were sufficient not only to produce such symptoms as headache, lassitude, furred tongue, foul breath, flatulence, &c., but also to cause a rise in the basal metabolic rate and of the blood-sugar, increased reaction times, and a diminished capacity for work. The symptoms were all promptly relieved when the rectum was emptied. Moreover, this voluntary constipation caused little or no increase in the urinary excretion of indican. It is probable that, as Mutch[43] suggests, it is in the small intestine—e.g., the lower end of the ileum, and, I think, in the cæcum, but not in the colon—that toxic substances may be produced and absorbed; and we may justifiably conclude that symptoms of so-called toxæmia may result either from mechanical rectal distension or from delay in, and the absorption of products of bacterial action from the small intestine. In the latter case the detoxicating function of the liver must be of importance.

There is clinical evidence to show that both simple constipation and genuine intestinal toxæmia may be factors in aggravating seborrhœic conditions such as acne, but the exact modus operandi is difficult to explain in either case.

"METADYSENTERY,"

WITH REMARKS ON A CHRONIC TYPE.

BY SIR ALDO CASTELLANI, K.C.M.G. (HON.), D.S.C., M.D. FLOR., M.D. CAIRO, F.R.C.P. LOND.,
PROFESSOR OF TROPICAL MEDICINE, TULANE UNIVERSITY OF NEW ORLEANS, U.S.A.; DIRECTOR OF TROPICAL MEDICINE, ROSS INSTITUTE, LONDON; LECTURER, LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE.

SOME years ago I suggested the term "metadysentery" to indicate various clinical types of colitis due to a group of bacilli which I called the metadysentery bacilli. These bacilli may be defined as follows: bacilli which similarly to the true dysentery bacilli (Shiga-Kruse, Flexner, Hiss-Russel, or dysentery-paradysentery bacilli) do not produce gas in any sugar but in contrast to them either clot milk and produce acidity in lactose-peptone-water or produce acidity in lactose-peptone-water without clotting milk. These bacilli were separated by Chalmers and myself (1919) into two groups, the genus Lankoides (milk clotted) and the genus Dysenteroides (milk not clotted); but at times a strain which appears at first not to clot milk may do so later on, and therefore in practice it is of advantage to combine the two groups into one under the term "metadysentery bacilli." It may be added that for this group Jacono has suggested the generic term "Castellanus."

Historical.

Some of the metadysentery bacilli have been known for years. *Bacillus ceylonensis* A and *B. ceylonensis* B were found by me in 1904 and 1905, their description being published in 1907. *B. gintottensis* I described in 1910; *B. madampensis* I isolated in 1910 and described in 1911; the first strain of *B. metadysentericus* was isolated in 1904, but was not named for some years. Chalmers and I created for these organisms two genera, Lankoides and Dysenteroides.

Nabarro has given much attention to this group of organisms; at one time he was inclined to identify them all with *B. coli anaerogenes* of Lembke. In a very interesting publication in the *Journal of Pathology and Bacteriology* in 1923 he says:—

> Lembke, in 1896, isolated from the excreta of dogs a coliform bacillus producing acid but not gas in glucose and lactose media, to which he gave the name *B. coli anaerogenes*. Between 1906 and 1912 Castellani isolated several varieties in Ceylon which he has named *B. ceylonensis*, *B. madampensis*, *B. bentotensis*. These organisms all agree in the property of fermenting sugars, &c., with the formation of acid alone, the difference between them being of a minor nature.

Nabarro further states that he first isolated *B. coli anaerogenes* in 1912, from a case of dysentery at the Wakefield Asylum. In 1921, during an investigation upon summer diarrhœa and other diarrhœal conditions in children, he isolated 30 strains of *B. coli anaerogenes* from 25 patients out of 107 investigated. It would appear, however, that the true *B. coli anaerogenes* produces acidity in great amount and very rapidly, and after repeated transplantations produces gas in certain carbohydrates.

Principal Types of Metadysentery Bacilli.

The following bacilli may be considered to belong to the group of metadysentery bacilli:—

(1) *Bacillus pyogenes fœtidus* Passet (1902). This and similar organisms, although belonging culturally and biochemically to the metadysentery group, do no seem to cause dysenteric symptoms or colitis symptoms. They were found in cases of abscesses. An interesting feature is that they are motile. (2) The bacilli found by me in certain cases of colitis and dysentery with or without fever, which I described with the names *Bacillus ceylonensis* A, *B. ceylonensis* B, *B. metadysentericus*. In addition to these bacilli, *B. gintottensis* and *B. madampensis* which do not seem to be pathogenic. (3) *Bacillus bentotensis* Castellani (1912). This bacillus was isolated by me in Ceylon in stools; it is motile, and with regard to this character is similar to *B. pyogenes fœtidus* from which, however, it differs with regard to biochemical reactions. (4) Several of the strains found by Duval in cases of infantile diarrhœa, in America, seem to me to belong to the metadysentery bacilli rather than the paradysentery group (Flexner). (5) Certain strains found by Nabarro, in England, in cases of infantile diarrhœa, although Nabarro, until recently identified them with *B. coli anaerogenes*. (6) The strains found in recent years by Sonne and others in certain cases of dysentery, although these may be identical with *B. ceylonensis* A, *B. ceylonensis* B, and *B. metadysentericus*.

I do not place among the metadysentery bacilli the *Bacillus coli anaerogenes* found by Lembke in dogs, as apparently after repeated transplantations it produces gas.

The pathogenic metadysentery bacilli may be separated into two principal types: (1) *B. ceylonensis* A type (including *B. metadysentericus*) and (2) *B. ceylonensis* B type. In the first type acidity in lactose-peptone-water is produced very slowly and may be almost absent, clotting of milk is slow or absent; indol negative or only a trace. In the second type production of acidity in lactose is rapid, clotting of milk fairly rapid, indol usually positive. Serologically, especially using my absorption method, several subgroups may be differentiated.

Bacteriological Description of the Various Species.

This has been given in a number of previous papers; among the recent ones I may mention one in the *American Journal of Tropical Medicine*, July, 1927, with the title, The Classification of Bacterial Dysenteries and of Dysentery Bacilli. There is therefore no need to enter into details, but the table showing the characters of the more important species may be found useful.

Clinical Syndromes: Chronic Metadysentery.

The clinical intestinal conditions in which organisms of the metadysentery group of bacilli have been isolated may be classified into: (*a*) *Acute*. With either dysenteric diarrhœa or simple diarrhœa. In certain cases fever may be present. (*b*) *Chronic*. Several types.

These organisms have also been found at times in obscure cases of fever in which intestinal symptoms may be very slight or lacking altogether, and paratyphoid has been suspected. I have under treatment at the present time one such case in London.

In this paper I propose to discuss again a chronic type characterised by recurrent attacks of simple

diarrhœa with absence or only occasional presence of dysenteric symptoms. The stools during the attack are fluid, brownish or yellow, at times frothy; as a rule, they do not contain muco-pus or blood, but there are a number of exceptions. Each attack may begin suddenly with severe abdominal pain, or only abdominal discomfort may be felt; it lasts from a few hours to several days. In the intervals between the attacks, and the intervals may be very prolonged, the patient may feel fairly well, but as a rule complains at times of light abdominal discomfort and flatulence; he often feels run down, tired, nervy, and not inclined for work. These cases go on for years, a little better, a little worse; they consult many practitioners, and are generally told they are suffering from colitis, or intestinal intoxication, or intestinal subinfection; sometimes the diagnosis mucous colitis and abdominal neurasthenia is made. Not rarely atypical appendicitis is suspected and the patient is operated on. Similarly, atypical cholecystitis may be suspected. The patients try all sorts of treatment, Plombières douching being probably the most popular and next to it streptococcal vaccines and various so-called intestinal disinfectants. The result is generally unsatisfactory. Some of these patients have a wretched life and are a burden to themselves and their families.

* Castellani; † Passet. St., strain. 0 = negative, viz., absence of clotting in milk, absence of acidity and gas in sugar media (the medium may become alkaline). + = positive, viz., presence of clotting in milk, presence of acidity and gas in sugar media, &c. A = acid. AG = acid and gas. Alk = alkaline. — = reaction unknown. As = acid slightly. Avs = acid very slightly. D = decolorised.

Note 1.—Some strains of *Bacillus ceylonensis* A at first produce acid in glucose and lævulose only, lactose is not fermented or only very slowly; milk is clotted very slowly. Strains P.D., O., Z., are serologically identical. Strain Sb. differs serologically.

Note 2.—The four strains of *Bacillus ceylonensis* B are serologically identical; strains R.R. and O. produce acidity in lactose rapidly; strain R.W. very slowly.

Note 3.—Certain strains may clot milk after prolonged incubation.

Illustrative Cases.

CASE 1.—Mrs. A. for two years before being seen by me had been suffering at intervals from attacks of diarrhœa with severe abdominal pains, the stools being brownish or yellowish, at times somewhat frothy, never containing any blood. She came to consult me in June, 1926. A bacillus was isolated from the stools, with the characters of the bacilli of the metadysentery group—viz., produced no gas in any sugar, produced acidity in lactose, clotted milk slowly. The blood agglutinated the bacillus isolated from the stool up to a dilution of 1 in 100, and the laboratory strain of *B. ceylonensis* B up to a dilution of 1 in 120. The bacillus was not agglutinated by blood of normal individuals. A powerful Shiga serum (titre for Shiga, 1 : 1000) obtained from Burroughs Wellcome, agglutinated it only up to 1 in 20. The lady was admitted to a tropical nursing home and was kept at complete rest in bed and on fluid diet. A course of *ceylonensis* B vaccine (peptone-water cultures killed by the addition of carbolic ½ per cent.) was given in minute doses. She gradually got better, and up to the present day has not had any more attacks. The agglutination for the bacillus isolated from the stools rapidly decreased; it is now negative.

CASE 2.—Mrs. B., an Englishwoman, had an acute attack of diarrhœa, she thinks, with a little blood and mucus, but does not remember with certainty, 14 years ago in Rome. She did not go to see a doctor, and did not even go to bed; since then she has never been quite well. Very often she has had abdominal discomfort and flatulence; as a rule, however, no diarrhœa. She came to consult me in August, 1926, because she was passing through a period of reacutisation with diarrhœa, the stools being liquid, of a brownish colour. A bacillus was isolated from the stool with the following characteristics: slow clotting of milk, no production of gas in any sugar, acidity in glucose. I thought at first that lactose was negative, but after three weeks a slight amount of acid developed. Serologically, the organism was identical with a strain of *B. ceylonensis* A isolated in Ceylon. The bacillus isolated from the stool was agglutinated by the patient's blood in a very high dilution (1 in 320); the laboratory strain of *B. ceylonensis* A was agglutinated in a dilution of 1 in 160.

CASE 3.—Mrs. H. has been suffering from rather obscure abdominal symptoms for many years; abdominal discomfort, flatulency, attacks of simple diarrhœa followed by long periods of constipation; there was apparently at times slight tenderness in the right lower abdomen; appendicitis was suspected and an operation was performed. The appendix did not seem to be diseased. The lady came to consult me in August, 1926, merely complaining of vague abdominal discomfort and of always feeling tired and ill. The blood showed high agglutination (more than 1 : 160) both for *B. ceylonensis* A and for *B. ceylonensis* B, all strains; none for *B. madampensis*.

Three strains of metadysentery bacilli were isolated from stools; one was agglutinated by patient's blood and by *B. ceylonensis* B serum; the third strain was not agglutinated by either the patient's serum or *B. ceylonensis* A or *B. ceylonensis* B sera. The third organism appeared to be identical with *B. madampensis*. It seems, therefore, that in this case the condition was probably due to a mixed infection—*B. ceylonensis* B and *B. ceylonensis* A.

I am indebted to Sir William Simpson for carrying out the necessary inoculations in rabbits to obtain the specific sera.

I may quote two cases of colitis with fever described by me in 1907.

(1) An Australian medical man, 24 years of age, arrived at Colombo from China in April, 1905. A week before reaching Colombo he began to feel ill with lassitude, headaches, diarrhœa—10 to 15 motions daily with no mucus or blood—irregular low fever. The disease lasted two months. The diarrhœa was followed by a long period of constipation. The convalescence was very prolonged, the patient suffering repeatedly from attacks of nervous tachycardia. A bacillus was isolated which clotted milk and produced acidity, but no gas in many sugars; I gave a description of the bacillus and called it *B. ceylonensis* B. The original strain is still in my possession.

(2) A retired German officer. Strongly built man, 50 years of age. No previous disease of any kind. Began to feel ill with malaise while on board a German steamer during the voyage from Aden to Colombo; irregular rises of temperature; slight diarrhœa. He never felt ill enough to remain in his cabin. As there was a case of enteric on board, the same disease was suspected in this patient, and he was accordingly advised to land at Colombo. During the first three days after landing in Colombo he felt quite well and was getting ready to go up country when suddenly, in the afternoon, his temperature rose to 103·2° F. There was slight shivering, severe headache, diarrhœa becoming a prominent symptom, 12 liquid motions being passed in a few hours. I saw the patient in the evening; temperature 102·4°, pulse 78; no roseola or any other rash; examination of the chest negative; spleen not enlarged; the stools, which were liquid and yellowish, did not contain blood or muco-pus. The fever lasted 16 days longer and its course was very irregular. The pulse always remained slow. The spleen could never be palpated, and roseola spots never appeared. The diarrhœa lasted for three days, and the stools never contained blood. The analysis of the urine was negative. Except during the first four days the patient did not complain of headache or of any serious subjective symptom.

Treatment consisted in the exhibition of the usual intestinal antiseptics and in keeping the patient on liquid diet. From the stools an organism was isolated which clotted milk, slowly produced acidity in glucose, but not in lactose (readings taken on the seventh day). I called the bacillus *B. ceylonensis* A. After several transplantations it became capable later on of producing acidity in a number of sugars, and it may produce slight acidity in lactose after two or three weeks' incubation.

Diagnosis and Distribution.

Diagnosis is difficult; the bacteriological examination of the stools may be negative very many times before metadysentery organisms are found. In the chronic cases what I have found most helpful is testing the blood for agglutination for the principal varieties of the group. My routine procedure is to test the blood of every suspicious case for agglutination for *B. ceylonensis* B, *B. ceylonensis* A, and *B. metadysentericus*. When the agglutination is higher than 1 in 80, as a rule repeated bacteriological examinations of the stools will reveal sooner or later the presence of metadysentery organisms, although, as I have already stated, many examinations may have to be carried out before a successful one is obtained. The stool for examination must be absolutely fresh.

The colonies on MacConkey's agar plates are delicate and after a day or two may have a pinkish or reddish colour.

A very similar chronic clinical syndrome may be found caused by *E. histolytica*; very rarely by bacilli of the true dysenteric group (Shiga-Kruse, Flexner, and Hiss-Russel or dysentery-paradysentery group). Only repeated and thorough microscopical and bacteriological examinations will enable one to make a differential diagnosis.

The condition is a cosmopolitan one; I have studied cases in which the infection was apparently contracted in Ceylon, India, Italy, the Balkans, Spain, France, Germany, the United States, and this country.

Conclusion.

The term metadysentery may be used to indicate a group of colites due to the metadysentery bacilli—viz., bacilli which in contrast to the true dysentery bacilli (Shiga-Kruse, Flexner, Hiss-Russel, or dysentery-paradysentery bacilli) either clot milk and produce acidity in lactose-peptone-water, or clot milk without producing distinct acidity in lactose-peptone-water, or produce acidity in lactose-peptone-water without clotting milk. This group of bacilli includes *Bacillus ceylonensis* A, *B. ceylonensis* B, *B. metadysentericus*, and several others.

In this paper attention has again been called to a chronic type of colitis due to the above-mentioned bacilli which in my experience is far from rare. In this type true dysenteric symptoms with blood and muco-pus in the stool are usually, though not always, lacking. The patient feels tired, nervy, has no appetite, complains of flatulence with occasional attacks of simple diarrhœa followed at times by long periods of constipation. The diagnosis is based on the presence in the blood of specific agglutinins and on the repeated bacteriological examination of the stool.

SOME POINTS IN THE DIAGNOSIS OF CARDIAC LESIONS IN CHILDREN.

By R. H. SIMPSON, M.D., M.R.C.P. Lond., D.P.H.,
PHYSICIAN, EAST LONDON HOSPITAL;
AND
LINDSEY W. BATTEN, M.B. Camb.,
M.R.C.P. Lond.,
ASSISTANT PHYSICIAN, EAST LONDON HOSPITAL; VISITING MEDICAL OFFICER, CHILDREN'S HOSPITAL, HAMPSTEAD.

Children, like patients of all ages, are brought to the physician from time to time for an opinion on the soundness of their hearts. It may be that some symptom, referable at least in the mother's opinion to the heart, has made her anxious; it may be that doubts or aspersions have been cast on the heart in the course of a routine examination at school or elsewhere.

The problem presented is of the greatest possible importance, and it is extremely desirable to reach a definite conclusion and to give an unequivocal opinion. If the heart is the seat of active disease, absolute rest is the first requisite for recovery, and it is wrong that the child should be up and about. If the heart has some congenital or acquired structural defect but healthy musculature, the problem is to determine as nearly as may be its powers and limitations, to explain the situation to the parents, and to plan the child's days so that work, play, and happiness are as little interfered with as possible. If the heart whose healthiness has been called in question is, in reality, sound, the importance of pronouncing it to be so can scarcely be exaggerated. To play for imagined safety by describing a heart of whose condition one is in doubt as "weak," and counselling a vague carefulness, is, in reality, to run the very grave risk of fixing upon the child a lifelong burden of fear, spoiling its happiness and usefulness, and perhaps even of manufacturing a chronic invalid. If there is doubt, as sometimes there is bound to be, the condition should be pronounced doubtful and diagnosis suspended for a limited period until it can be established with certainty. The position once explained and accepted, an interim régime can be prescribed which may be allowed to err on the side of caution, but the necessity of establishing the diagnosis at the earliest possible moment must never be forgotten.

Thus, the problems of cardiology in childhood have a special importance and urgency; first, because the child's heart has far greater powers of recovery and adaptation than the adult's; and, secondly, because the child, more than the adult, is dependent on our judgment; what we say about the heart may have lifelong consequences, and it is our bounden duty to make sure of the truth before we speak.

Although the degenerations in muscle and vessels which complicate the problem after middle life are absent, the position of the heart in the chest is relatively variable and is easily affected by exocardial factors, murmurs of all kinds are commoner than at any other time of life, the heart and blood-vessels are especially sensitive to nervous influences, and the heart muscle, though immune from degenerations, is relatively susceptible to intoxications and inflammations. The liability of children to rheumatism makes it particularly necessary to consider whether any lesion which may be found is active or not.

Investigation of the Case.

No attempt will here be made to describe or classify the many conditions which may be met with. It is intended rather to indicate how investigation can best be carried out, and to discuss the relative value of various symptoms and signs in the child as compared with the adult. The methods of investigation which can be employed are history-taking, physical examination, efficiency tests and instrumental investigation by means of skiagram, electrocardiogram or otherwise—of which direct examination is, in these cases, the most valuable.

The *history* is of less value than in an adult with similar complaints, especially as the greater part of it cannot be obtained from the patient himself. It is important to consider the type of parent who is giving it, and so to form some opinion of the weight which may be attached to the story, and more especially of the kind of influences to which the child is subject at home. If the mother has been told already that the child has a "weak" heart, she should always be asked what, if anything, she noticed to be amiss before this time. In this way it is possible to disentangle the actual features from those which may have been suggested by previous questions or which an anxious parent imagines to be appropriate to the occasion.

Under *family history* inquiry should be made into rheumatism and rheumatic heart disease. A definite history of acute rheumatism, chorea, or valvular disease of the heart in a near relative should be given some weight, but it should be remembered that the expression "rheumatism" when used of adults connotes, in lay parlance, almost any kind of pain not having an obvious cause, and that some form of heart disease or heart failure overtakes many previously healthy people in the late years of their lives. It must also be remembered that acute rheumatism occurs often enough in a single member of a healthy family. It is useful as an aid in the assessment of symptoms to know whether the patient is an only child, the baby of the family, or even the only girl in a large family of boys. Any one of these states has power to produce, and still more to magnify, subjective or functional symptoms.

In the individual child *symptoms* may be many, few, or none, and their value is most difficult to assess. The relevant ones fall into two classes, those of conditions causing cardiac damage and those referable to such damage.

Of the first, the "rheumatic group" is, of course, by far the most important. A definite history of acute articular rheumatism or of chorea is of the utmost significance, and may rightly be allowed to colour our view of doubtful physical signs. A history of tonsillitis, especially if recurrent, and of scarlet fever is also important, but it is questionable policy to search by leading questions for the "minor manifestations" of rheumatic infection. A history of occasional aches and pains, of transient fever, sore-throats, or fidgetiness can be elicited in a large proportion of all children. Whether it emerges probably depends at least as much on the mentality of the mother and child and the outlook of the doctor as on any physical factor, and neither its presence nor its absence should be allowed much weight. A definite account of "growing pains" cannot be ignored, but should not be over-valued in estimating the state of the heart. The insidious type of mitral stenosis, which is suspected far more often than it is found, develops quite independently of any history of rheumatism.

Symptoms referable to the heart itself are fewer and less reliable in children than in adults, and considerable lesions, especially of the mitral valve, may exist without producing any noticeable general effect. In young adults dyspnœa on exertion and œdema of the feet are relatively early and constant symptoms of myocardial weakness; in children both are uncommon, and both, but especially the second, indicate an advanced and serious degree of cardiac insufficiency. The place of dyspnœa as an early symptom is, to some extent, taken by listlessness and disinclination for activity, which, in a child of previously energetic disposition, are somewhat suggestive of cardiac insufficiency. Cyanosis, except in congenital lesions, is also uncommon and of serious import; the same may be said of cough.

There have also to be considered symptoms which parents ascribe to the heart, though the medical man is less likely to do so. Such are præcordial pain, fainting, palpitation, and changes of colour. Of these, it may be said that though any or all of them *may* be due to heart trouble, this is their least common cause. An attempt must be made, however, to explain them and to assess their value, and in doing so, it is of the first importance to discover the circumstances in which the symptom occurred. A faint at the dentist's has a very different complexion from a faint after running upstairs, and, in general, it is true to say that unless brought on by exertion such symptoms do not reflect on the heart's efficiency, and by no means always even then. Thus it often happens that but little help is to be got from history and symptoms, however carefully investigated, and we must turn to the *examination* of the child.

This examination must be thorough and general, and on no account be limited to the heart alone. The child's general aspect is of some importance and assistance. The thin sallow child of poor physique, often with dilated pupils and brisk reflexes, is not a typical rheumatic subject, but is prone to vasomotor disturbances including "functional" murmurs, and also to subjective symptoms arising from introspection and anxiety. The resemblance of these children to one or other parent in both physical and mental make-up is often striking and materially assists diagnosis. If the mother has the same pasty, anxious, and debilitated appearance as the child, but no heart disease, we should be chary of blaming the child's heart for his ill-looks; an inheritance, mental outlook, and environment common to both are much more likely to be the cause.

A child under 5 is unlikely, and one under 3 very unlikely, to have rheumatic heart disease. The typical rheumatic subject is a well-grown, well-nourished, and pleasant-looking girl of 10 to 16 who, unless the infection is active or the heart seriously damaged, presents little appearance of ill-health. If the disease is appreciably active there is almost always some degree of pallor with general listlessness and apathy. The pallor of aortic incompetence and the cyanosis of congenital pulmonary stenosis, and (though much less) of severe mitral stenosis are well known, but there is no facies of minor mitral lesions or of slight myocardial insufficiency. Severe valvular lesions, acquired early in life, gravely impair nutrition and growth.

The condition of the tonsils and tonsillar glands should always be noted, and attention may then be turned to the heart itself. There can be no exception to the rule that every heart should be examined in the erect and recumbent positions, and to this may well be added examination in the left lateral position and after exercise.

Inspection in severe cases may show præcordial bulging, which occurs more readily in children than in adults, and it will generally show whether the heart is acting quietly or excitedly and give some information as to the position, mobility, and character of the apex-beat—information which will be extended and confirmed by palpation. It is not always recognised that the position of the apex-beat is not the same in children as in adults. Until the age of 5 it is generally in the fourth space, with each succeeding year more commonly in the fifth, where it is established by puberty. Not only is it higher than in adults, it is also further out. It is definitely outside the nipple line in the first four or five years of life, in it until the age of 10 and internal to it by 14. It is higher and nearer the middle line when the child is lying down than when he is erect. These variations are associated with the fact that the heart is more horizontal and is relatively larger in childhood than in adult life, and also with changes in the shape of the chest. The point which is chiefly to be noted is that an apex-beat in the nipple line in a child under 14 is not, in itself, evidence of cardiac enlargement or displacement.

Very valuable information about the character of the heart-beat and the presence or absence of hypertrophy is gained by palpation with the flat of the hand, and this should never be omitted. The size of the heart should be judged chiefly by percussion which, in children, with their relatively thin chest walls, gives clear-cut and convincing results. In auscultation, again owing to the thin chest wall, both normal and adventitious sounds are heard distinctly, and murmurs are often diffuse. Reduplication or splitting of either sound is common and of little importance. In young children the pulmonary second sound is distinctly louder than the aortic. This may persist as late as puberty, and in no way supports a tentative diagnosis of mitral disease. The so-called third heart sound deserves attention because it is apt to be mistaken for the mid-diastolic murmur of mitral stenosis. It is heard near the apex of the heart in quite a large proportion of children, and consists of a short sound, occurring in diastole rather longer after the first sound than a reduplication. It is said to be due to the sudden tension of the mitral valve in diastole and has no evil significance. It may be added that normal sounds, quiet, orderly, and of good tone, are strong presumptive evidence of the heart's integrity and should not be lightly disregarded.

Murmurs are responsible for more troubles and difficulties than all other cardiac signs and symptoms put together, and are to be heard in a large proportion of children at one time or another. They may be divided according to their significance into three groups: transient or accidental murmurs which are of no pathological significance, temporary or atonic murmurs due to a relaxation of the normal tone of the myocardium, and permanent or organic murmurs which may be congenital or acquired.

The first are very common, and are notably inconstant and variable. They are systolic in time, usually heard best at the apex or pulmonary base, are not transmitted or accompanied by thrills or by evidence of cardiac enlargement or insufficiency. They vary in loudness but can, as a rule, be distinguished without much difficulty. In cases of doubt, a second examination after an interval will often settle the question.

Atonic murmurs may occur in anæmia or in any toxic or infective state. They are soft blowing sounds, localised, or, at most, conducted for only a short distance. One of the commonest varieties is a systolic murmur, heard at the apex, and due to mitral incompetence. Only the course of events can show with certainty whether this incompetence is due to endocarditis or to a temporary yielding of the mitral orifice. If there is reason to suspect active or recent myocarditis or myocardial intoxication and if the murmur is soft, purely systolic, and not very widely conducted it is wise to assume that it is not due to endocarditis until it proves itself to be so by persisting when the myocardium has recovered beyond dispute. This may take time. Such murmurs may persist in spite of six or eight months' rest in bed, and then disappear completely with the return of full myocardial efficiency.

The classical signs of mitral stenosis—the rough crescendo presystolic bruit with its thrill and slapping first sound—occur only when the lesion is established. In a child the sign of developing stenosis is not a roughening of the first sound, but a mid-diastolic murmur, best heard and sometimes only heard after exercise. It must be searched for with care, and if it be found it is wise to confirm its presence by a second examination, having regard especially to its relation to exercise, before it is made the basis of a definite diagnosis. It must be remembered that a diagnosis of mitral stenosis carries with it weighty and serious implications as to permissible exercise and probable length of life. If it is overlooked when present the child's chance of acquiring compensation may be jeopardised; if it is wrongly diagnosed, a potentially happy and useful life may be changed to one of anxiety and invalidism.

The signs of aortic lesions in children are essentially the same as in adults. They are usually associated with mitral lesions, but are much less common. Pure stenosis is extremely rare. The diastolic murmur of incompetence is easily overlooked; it is soft, sometimes very soft, and is generally best heard to the left of the sternum rather than at the aortic base. A certain amount of incompetence may result simply from loss of muscle tone, but this is much less common than at the mitral valve. When it occurs, it is perhaps most frequently in association with a severe anæmia.

In many cases some form of exercise-tolerance test is necessary in order to gauge the functional efficiency of the heart. A standard exercise should be performed, the manner of its performance be noted, the pulse counted, and the heart examined as with adults, but the result in children must be weighed with caution. Not only is the "normal" pulse-rate far more variable in children than in adults, but it is also more readily disturbed by emotion or excitement. Many children exhibit a tachycardia whenever they are examined, no matter how well they know the doctor, and the acceleration of the pulse after exercise is often obviously due in part to the excitement of performing it and will persist while the feeling of excitement lasts, often for much longer than the standard one or two minutes. In such children the manner of performing the test, the child's colour, and the presence or absence of dyspnœa are the best indications of the heart's response to the effort, and none of these is infallible.

Serious disorders of rhythm are rare in children. Sinus arrhythmia—the rhythmic variation in gear with the respiratory movements—is normal and often marked; a few deep slow breaths should suffice to differentiate it from other forms. It disappears on exercise and in general myocardial infections and intoxications, and its return in these latter cases is a sign of myocardial convalescence. Premature contractions or "extrasystoles" can be identified by the combined use of a finger on the pulse and a stethoscope at the apex. Unless very frequent or elicited instead of abolished by exercise they are of little import. Other disorders of rhythm are, in children, decidedly rare.

In difficult cases, when, for example, the significance or insignificance of an unusual murmur has to be determined and clinical evidence is not conclusive, valuable help may be gained from X rays or the electrocardiograph, but in most cases all pertinent questions can be answered without them.

Summary and Conclusions.

An attempt has been made to indicate the main differences between child and adult cardiology, and to point out some of the problems peculiar to children and how they may be faced.

The diagnosis of fully developed lesions is, on the whole, easier in children than in adults and even prognosis is in some respects less difficult than it becomes after middle life, but the problem of the early developing lesion is at times one of great difficulty. To form an opinion on the state of the heart at the moment of examination may not be hard, but there will arise in the mind the question "is this heart the seat of active infection—is this slight abnormality the first sign of serious trouble?" To answer this question a thorough and general investigation of the child and his history will be necessary, and in some cases a period of observation while the diagnosis remains in doubt cannot be avoided. Such cases are, however, the exception and not the rule. In very many cases brought up for decision the diagnosis of "healthy heart in a healthy child" can be made with confidence. In another group the nature and degree of cardiac damage can be stated with reasonable certainty, present infection excluded, a suitable régime instituted, and a watch kept for any recurrence of active trouble. In doubtful cases the necessity for reaching a decision at the earliest possible moment should never be forgotten.

The insidious nature of the rheumatic infection and the variety of its manifestations has lately been emphasised and even advertised. Parents, teachers, and others responsible for the health of children take early and serious note of fidgetiness and limb pains (though perhaps less than they might of febricula and tonsillitis). The doctor, knowing well what damage rheumatic infection can do is tempted to an attitude of extreme caution. This is, from one point of view, amply justifiable, but it must be remembered that while childhood is the time when rheumatic infection does its worst, it is also the time when accidental and insignificant murmurs are commonest and the pulse-rate most variable and easily disturbed, and further, it is the time when character and mental outlook are being formed. Six months of rest in bed to recover from cardiac dilatation may prove to be soundly invested; six months of doubt and caution with restrictions of exercise and play in an atmosphere of anxiety are unlikely to stay the progress of an insidious carditis, but are well calculated to sow the seeds of a cardiac neurosis difficult or impossible to eradicate.

ROYAL LONDON OPHTHALMIC HOSPITAL.—The annual report of this institution, which is still commonly spoken of as "Moorfields Eye Hospital," although 30 years have elapsed since it was removed to the City-road, shows that last year closed with a credit balance, after an expenditure of £31,607. There were 2581 in-patients who stayed, on the average, 16 days and cost £6 10s. 8*d*. each; there were 45,000 new out-patients who cost 6s. 3*d*. each. Considerable extensions are now imperative, including enlargement of the out-patients' department, accommodation for private patients, and additional nursing staff, and extension of the medical school and laboratories.

THE RADIOGRAPHIC AND MICROSCOPIC APPEARANCE OF
INFECTION OF THE TEETH AND THE SURROUNDING TISSUES.

BY DAVID A. IMRIE, M.D. LAUSANNE,
L.R.C.P. EDIN., D.M.R.E. CAMB., L.D.S. GLASG.,
HON. RADIOLOGIST, DENTAL DEPARTMENT, UNIVERSITY COLLEGE HOSPITAL; CLINICAL ASSISTANT, X RAY DEPARTMENT,
ST. BARTHOLOMEW'S HOSPITAL.

THE introduction of X ray examinations has provided the clinician with an additional and very valuable eye as an aid to diagnosis and prognosis. To obtain the greatest value from such examinations the radiologist should act as one of a team. The interpretation of dental radiograms is not easy. There are so many factors causing distortion of the images—the curving of the film in the mouth and the angle of incidence of the beam of X rays on the film when it is being activated. Add to this the wide range of variations of the dental arches and palates of different individuals, and it will become obvious that only the most painstaking technique is likely to lead to satisfactory results. Here, almost more than in other branches of radiography, the slogan "Only the best is good enough" applies.

Tables, setting out the angles of incidence for the beam of X rays upon the film for the various teeth, must be inaccurate, considering the wide variations of individuals. This angle must depend also upon the tilt of the patient's head. Only by experience and practice then is it possible to produce accurate representation of the teeth and surrounding tissues upon the films. Fortunately, it is easily possible to obtain clarity of detail, for the film can be placed in very close apposition to the objects under examination and there is a minimal amount of extraneous matter to be traversed by the beam of X rays in its passage to the film. Only the interposition of the nose, in the case of the upper incisors, and of the malar bone in the case of the upper molars, materially obscures this clarity.

The production of radiograms of fine detail, then, enables minute variations from the normal or healthy to be quickly and surely recognised, and it was with the purpose of proving that the radiographic interpretation of these alterations was true that the investigations about to be described were carried out. The radiographic appearance of infected bone in osteomyelitis and tuberculous disease is established and proved. The changes which occur in the bones of the jaws when these are infected from the mouth are essentially the same, although in the vast majority of cases the process is much more chronic. Yet the fine detail of a dental radiogram renders the detection of even small localised patches of infected bone quite possible.

The alterations produced in the bone as the result of infection are three: 1. Thickening of the trabeculæ with concomitant reduction in size and shape of the intertrabecular spaces—i.e., sclerosis. 2. Rarefaction of the trabeculæ with the necessary enlargement of these spaces. 3. Destruction varying from the loss of a few of the bony trabeculæ to the production of macroscopic cavities in the bone.

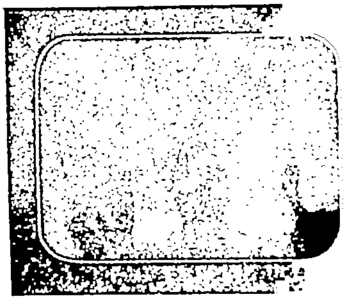
Sclerosis may be regarded, generally, as a defensive reaction of the bone to the advance of the infection. Rarefaction and destruction, then, will be regarded as a comparative lack of defensive power of the bone to the advance, due either to relative weakness of the tissues or to relative strength of invasion.

The investigations which were carried out to prove these points, although numerically weak, were valuable in that they were consistent with clinical evidence and with themselves, and they may stimulate others to carry on the experiments. There are eight cases. Small pieces of bone of the alveolar process were removed from around teeth, said to be infected upon X ray examination, by a small trephine of about three millimetres, mounted in the handpiece of a dental engine.

The preparation of the specimens was as follows. 1. Fixation in 40 per cent. formalin in physiological salt solution. 2. Fixation and decalcification in Bouin's fluid for two to three days. 3. Embedding in paraffin. 4. Cutting and mounting. 5. Staining with (*a*) hæmalum and eosin; (*b*) hæmalum, eosin, and saffron; (*c*) Gram's stain.

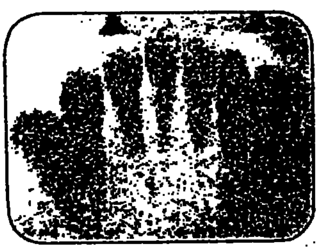
Specimen 1, taken from the dried skull of a dog, was decalcified with trichloracetic acid. The staining by hæmalum, eosin, and saffron brings out fibrous tissue more clearly. Gram's stain was used in the hope of demonstrating some micro-organisms in the deep bone. No attempt was made to produce cultures, for the technique of removing the bone was not sufficiently rigorous to exclude the possibility of contamination from the tissues of the mouth. All the cases were examined by dental radiograms before removal of the piece of bone.

FIG. 2.



Sclerosis around an infected cyst. The periodontal membrane is thickened and the lamina dura is absent. The trabecular network is replaced by compact sclerotic bone.

FIG. 3.



The lower incisors of a patient suffering from a "toxic" heart. The lamina dura is absent, the periodontal membrane is irregularly thickened, the trabeculæ are hazy, and tracks can be seen leading from the roots to the deeper bone.

Description of Specimens.

1. A fragment of bone, taken from the dried skull of a dog which had been the subject of marginal osteitis. Radiographically there is extensive loss of bone about the necks of the teeth. A mild sclerosis is noted around the apices of the roots. The radiograms are unnaturally clear owing to the lack of soft tissues. The site of the removal of the bone was at some distance from the margin. Under the microscope the bone tissue appears normal, except that, having been preserved dry, the marrow tissue is shrunk. Animals rarely show symptoms of deep bone infection.

2. A fragment taken from bone surrounding an infected cyst. Radiographically the bone is densely sclerosed, and the shadow of the lamina dura is lost in this sclerosis. The trabecular shadows are hazy, and the intertrabecular spaces are rounded (Fig. 2). Microscopically the bone trabeculæ are broader than usual. They show parallel striæ, as though fresh deposits of calcium salts had been laid down. These striations resemble the formations seen in tree trunks. The osteogenetic cells are normal, so that these lines of "secondary calcification" only accentuate the normal appearance. In the marrow there is abundance of fibrous tissue infiltrated with lymphocytes. Osteoclasts are numerous at the borders of the trabeculæ. In places they lie in little "niches" in these structures.

3. A fragment taken from around the lower incisors of a patient suffering from a "toxic" infection of the heart. Radiographically the summits of the interdental septa are destroyed, and there is little reactive sclerosis. The shadows of the lamina dura are indistinguishable, and the periodontal membrane shadows are irregularly thickened. The trabecular shadows are fine and hazy, and tracks are to be seen leading from the roots downward to the deeper bone (Fig. 3). The slides show a piece of bone with the periodontal membrane and a fragment of root. The trabeculæ show some rare deposits of "secondary calcification." The bone cells appear healthy, and are of average numbers. In the marrow the blood-vessels appear dilated and contain numerous polymorphonuclear leucocytes. These are situated against the walls of the vessels, and in places have traversed the walls and are lying in the surrounding tissue. At the borders of the trabeculæ the osteoclasts are numerous and in places are situated in "niches," apparently eaten into the bone. The cement and dentine of the tooth do not exhibit any pathological abnormality, and staining by Gram did not reveal any micro-organism.

4. A piece of bone taken from around the apex of an infected tooth. Radiographically the point of a broach, which had been passed through the apex, is seen. The trepanning was undertaken to remove this. At the apex is an area of "rarefaction," surrounded by dense hazy sclerosis. The shadow of the lamina dura is absent and the periodontal membrane is much thickened and irregular. The fragment of cement and dentine removed do not reveal any pathological change under the microscope. The bone is partly compact and partly cancellous. The trabeculæ do not show any "secondary calcification"; there is some increase of fibrous tissue in the marrow and also a slight general infiltration of lymphocytes. Osteoclasts, situated around the borders, are not numerous. In the periodontal membrane at the apex is an abundant accumulation of lymphocytes, and the limits of the bone are irregular. Staining by Gram was negative.

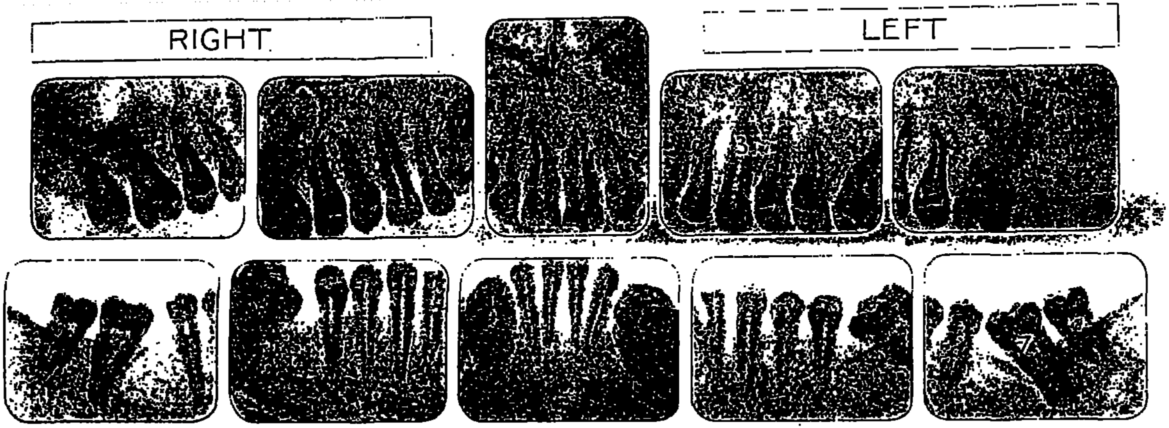
5. A fragment of bone removed during apicectomy. It was taken at a distance of about three millimetres from the apex. Around the apex the bone is sclerosed and hazy in the radiograms, and the intertrabecular spaces are rounded and diminished in size. There is little microscopical alteration in the bone cells, and the trabeculæ do not show any change. The periodontal membrane also is normal. In the slide stained by Gram, although no organisms were detected, there is a definite diffuse infiltration of lymphocytes in the bone-marrow. The slides were prepared from different areas of the specimen.

6. A fragment of bone taken from the edentulous jaw. The teeth had been removed two years previously. The trabecular shadows are thickened in places, but still hazy. A compact covering layer has not yet formed upon the surface of the alveolar process, an indication that healing is not yet complete. The bone cells are microscopically normal. The trabeculæ are thick, and lines of "secondary calcification" are well shown. The marrow tissue is invaded by excess of fibrous tissue. In places this is arranged in dense bundles. Where this tissue looks younger there is augmentation of the capillaries and a generalised infiltration of lymphocytes. At the borders of the trabeculæ the osteoclasts are in excess, and are often to be seen lying in little bays in the bone.

7. A fragment taken from the bone surrounding an infected cyst. The trabecular shadows are hazy and the limiting margin of the cyst ill-defined. Osteoblasts are numerous in the bone, in which are noted lines of "secondary calcification." In the marrow there is an increase of young fibrous tissue, and in places an infiltration of lymphocytes. Staining by Gram was negative.

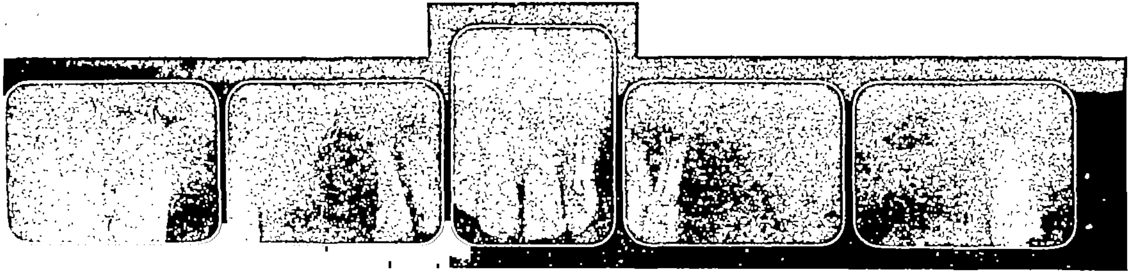
8. A fragment of bone taken with the tooth in extraction from a jaw the subject of osteitis deformans. In this series of radiograms (Fig. 4) the contrast with those of the normal bone is very striking (Fig. 1). The bone has lost its characteristic reticulate form and has acquired an appearance best described as that of ground glass. The roots of many of the teeth are exostosed, and the shadows of the lamina dura have disappeared. In spite of the bulbous roots, the teeth were easily removed by the dentist. The bone was soft and "springy" in consistence. Under the microscope the bone has a quite particular appearance. The trabeculæ are short, as if broken, and appear to have been invaded by medullary spaces. Some few lines of "secondary calcification" are still noted, and in places the trabeculæ are invaded and replaced by fibrous tissue, well shown by staining with saffron (Fig. 5.) The bone cells appear normal, but in the fibrous tissue the cells are shrivelled or lost. Normal marrow is completely absent and is replaced by large spaces, having a rounded and irregular cystic formation. The lining of these cysts is composed of fibrous tissue which in some parts is placed against the bone trabeculæ, while in other parts osteoclasts intervene. Where the bone is replaced or apparently being replaced by fibrous tissue osteoclasts are numerous, and are sometimes seen surrounded by this fibrous tissue, in which is a mild infiltration of lymphocytes. Coloration by Gram proved negative.

Some Notes on Case 8.—Aged 56, this patient came for routine examination of the teeth and jaws. Up till then



Complete survey. Each tooth is shown clearly at least once. There is some destruction of the summits of the interdental septa, particularly of the posterior teeth, with accompanying sclerosis. A small area of localised hazy sclerosis is to be seen at the apex of |3. There is well-marked hazy sclerosis also of the bone surrounding the roots of |7. Elsewhere the supporting bone is fair.

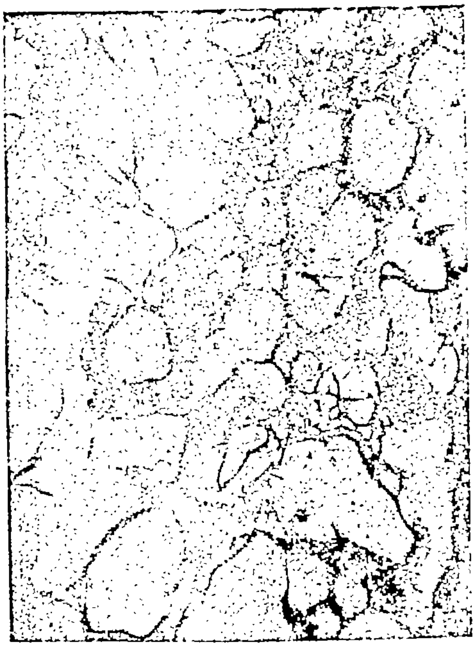
FIG. 4.



Radiograms from a jaw affected by osteitis deformans. The bony tissue looks like ground glass, the lamina dura is absent, and the periodontal membrane is irregularly thickened. The contrast is striking between this bone and that shown in Fig. 1.

there was no suspicion of osteitis deformans and the only clinical sign, albeit somewhat remote, that could be elicited was that her brother had remarked that she had become "bow-legged." Examination of the limbs by X rays did not reveal any curving of the bones, but there may have been slight alteration of the shape of the necks of the femora.

FIG 5.



Microphotograph of cancellous bone. × 90. The trabeculæ are irregular and the medullary spaces have undergone a cystic transformation.

The skiagram of the skull showed a suspicious thickening of the vault, but the change was not sufficient to warrant a diagnosis upon that alone.

The slide (Fig. 5) does not show all the characteristics of bone subject to this disease, perhaps because the change is very early, and also because the bone is infected.

In Specimen 1 there were no signs of inflammation in the bone, and the radiographic appearance was brilliantly clear. In Specimens 2, 4, 5, 6, and 7 there was lymphocytic infiltration of the marrow, excess of osteoclasts, and the delicate network of the bone had become more coarse and the trabeculæ thickened and hazy. Where the bone trabeculæ had become thickened the so-called lines of secondary calcification appeared. In Specimen 3 there was an osteoporosis. The bone trabeculæ are finer. The infiltration of the bone-marrow by polymorphonuclear leucocytes is an indication of a more acute inflammation. In Specimen 8 normal bone-marrow was absent. The bone trabeculæ were short and in certain sites replaced by fibrous tissue. In this case the lymphocytic infiltration warranted the removal of the teeth. The radiographic image of the alveolar bone in this disease has an appearance quite particular. It resembles that of ground glass.

Conclusions.

1. None of the slides revealed micro-organisms. Perhaps bacteriological culture would be necessary to establish their presence.

2. The osseous lesions are those that result from inflammation.

3. The radiographic appearance corresponding to the inflammatory lesions are: (*a*) Sclerosis, when the trabeculæ present the so-called lines of secondary calcification. (*b*) A haziness of the trabecular shadows when the microscopic examination revealed the signs of inflammation. (*c*) This inflammation is accompanied by sclerosis when the inflammation is chronic. On the contrary, when the inflammation is acute sclerosis is absent.

4. The histological and radiographic examinations correspond in general with the clinical findings.

5. The particular image of the bone in the dental radiograms of the case of osteitis deformans may permit of an earlier diagnosis of this malady.

CHORDOTOMY IN THE TREATMENT OF OSTEOARTHRITIS OF THE HIP.

BY A. S. BLUNDELL BANKART, M.CHIR., F.R.C.S.,
ORTHOPÆDIC SURGEON TO THE MIDDLESEX HOSPITAL; SURGEON TO THE ROYAL NATIONAL ORTHOPÆDIC HOSPITAL AND THE HOSPITAL FOR EPILEPSY AND PARALYSIS, MAIDA VALE.

OSTEOARTHRITIS, particularly when it affects the hip-joint, is one of the classical diseases of old age, and it is often difficult to treat when palliative measures have failed and the patient is crippled with pain and deformity.

It is essentially a senile degeneration of the joints characterised by atrophy and eventual disappearance of the articular cartilage in the centre of the joint, with hypertrophy leading to the formation of osteophytic outgrowths at the periphery. It is therefore a true arthritis *deformans*, but unfortunately this term has been used to include other conditions besides osteoarthritis. As will be seen presently, the age of the patient is not the sole factor in determining this "senile" type of degeneration, and osteoarthritis, particularly of the monarticular traumatic variety, is often seen in comparatively young subjects. But most of the patients are at least middle-aged or elderly and, it may be remarked, unsuitable for drastic surgical operations upon the affected joints.

During life the joints are not passive pieces of mechanism, but living structures which react to use like other living tissues. Every functional use of a joint is in a sense an injury—that is, friction and pressure tend to wear away the opposed articular surfaces. This normal wear and tear is at once made good by the increased blood-supply and nutrition which always accompanies function in normal tissues; hence the balance between wear and repair is dependent upon an adequate vascular response to function. If for any reason the vascular response in a joint is deficient, so that the process of repair is not equal to the demands made upon it, the joint simply begins to wear out and the cartilage becomes worn away where the friction and pressure are greatest. But the products of degeneration act as irritants to living tissues, so that in addition to degeneration in the centre of the joint there is also irritation, which makes itself evident in hypertrophic changes at the periphery where the blood-supply is still abundant.

Thus the characteristic features of osteoarthritis are degeneration leading to atrophy, erosion, and eventual disappearance of the cartilage in the centre of the joint, and hypertrophy leading to the formation of osteophytes at the periphery.

In old people the vascular response to function is less efficient than in the young, and often the power of repair is insufficient to make up for the normal wear and tear in a joint, so that the joint begins to wear out. Osteoarthritis is then a polyarticular affection beginning more or less simultaneously in many joints, although usually some of the larger joints, such as the hips, shoulders, or knees, are most obviously affected first. Naturally, any condition which greatly increases the wear of a joint, such as over-use, excessive weight-bearing in the case of the lower extremities, or repeated injuries, may predispose to or initiate the onset of osteoarthritis. So also any condition which enfeebles the vascular response—for example, arterio-sclerosis, endarteritis, or other circulatory disorder—may do likewise.

It has already been remarked that "senile" degeneration is not necessarily confined to the aged, and that anything which permanently interferes with the blood-supply of a joint may bring about similar changes at a much earlier age. Thus injury sufficiently severe to produce lasting effects is a common cause of monarticular traumatic osteoarthritis.

Lastly, osteoarthritis may be superimposed upon other forms of chronic joint disease, such as rheumatoid arthritis, for precisely the same reason, and failure to recognise this sequence has led to endless confusion between these entirely different diseases. There is no evidence whatever that osteoarthritis properly so-called is due to any infective or toxic agency.

Treatment.

From the very nature of the disease it is obvious that there is no actual cure for osteoarthritis. Exacerbations of pain and stiffness may occur from time to time and subside with or without treatment. But the fundamental pathological changes in the joints are *permanent* and slowly progressive.

Treatment consists in (*a*) palliative measures for the relief of pain and stiffness, and (*b*) surgical operations also for the relief of pain, or less often for the correction of deformity. Palliative measures, comprising various forms of physiotherapy and hydrotherapy, all resolve themselves into different ways of producing an increase of the local blood-supply, and their effects usually last just so long as the treatment continues, or a little longer. Many cases of osteoarthritis have their teeth, tonsils, and appendices removed without benefit to their arthritis, while vaccine therapy, founded as it is upon an erroneous conception of the disease, is equally futile.

It would seem rational to take the body-weight off a painful hip-joint that is wearing out. But elderly patients, especially if they are fat and heavy, do not take kindly to a calliper splint, and the relief so obtained seldom compensates them for the added discomfort.

In the earlier stages of the disease, before there are marked osteophytic outgrowths, much of the pain and stiffness may be due to fibrous adhesions at the periphery of the joint, and in some such cases a great improvement may be secured for a time by forcible manipulation under an anæsthetic.

Operative Treatment.

When palliative measures have failed, and the patient is crippled with pain and deformity, operative treatment may be indicated despite the fact that many of these patients are poor subjects for surgical interference. Practically only two operations are performed nowadays for the relief of painful osteoarthritis of the hip—namely, arthrodesis or destruction of the joint, and arthroplasty or reconstruction of the joint.

It is generally agreed that arthrodesis is the surest way of relieving pain in the joint. As usually performed, it is a very severe operation, entailing disarticulation of the head of the femur, the removal of the articular cartilage from both the head and the acetabulum, the replacement of the head, and prolonged fixation of the limb in plaster afterwards. Even then it is by no means assured that bony ankylosis will follow, although the pain is usually relieved. The modification of arthrodesis described by Albee consists in removing approximately the upper one-third of the femoral head by a horizontal cut, leaving a flat surface which is then brought into contact with a corresponding flat surface cut with a chisel in the roof of the acetabulum. This operation looks very simple on paper—for example, in a flat skiagram—but most surgeons have found that it is impossible to bring the two cut surfaces into contact without either reducing the diameter of the head of the femur or considerably enlarging the acetabulum.

Arthroplasty or reconstruction of the hip, as it is now the fashion to call it, is an attempt to form a new joint which shall be reasonably painless and yet retain some useful movement. The classical operation of J. B. Murphy has not yet fulfilled the hopes which he and others entertained for it. The operation now usually performed consists essentially in excision of more or less of the head of the femur and transplantation of the great trochanter to a lower level on the shaft of the bone, so as to give greater leverage to the muscles attached to it. It is by no means a trivial operation in an elderly patient, and the results as regards both the relief of pain and the preservation of useful movement are uncertain.

The operation described by Robert Jones for producing pseudarthrosis at the hip without disarticulation of the head of the femur is seldom performed nowadays. It may give relief of pain, but at the cost of great instability. Excision of osteophytes from the periphery of an osteoarthritic joint (cheilotomy) is utterly useless; it does not relieve either pain or stiffness.

From the foregoing considerations it is clear that the accepted treatment of osteoarthritis of the hip is extremely *unsatisfactory, there being no middle* course between ineffective palliative treatment and drastic surgical operations for which the majority of the patients are entirely unsuited. This has induced me to approach the subject from an entirely different point of view—namely, the relief of pain regardless of its local origin.

Chordotomy.

Clinically, the dominant feature of osteoarthritis is pain. Pain drives these cases to the surgeon, and pain is almost the sole indication for drastic operations, such as arthrodesis or arthroplasty in this disease. If sensibility to pain is abolished in an osteoarthritic joint, the patient is not only relieved of his suffering immediately, but he is enabled to recover much of the mobility which hitherto has been prevented by pain and muscular spasm. Sensibility to pain can be completely and permanently abolished by section of the anterolateral (spinothalamic) tracts in the spinal cord at a level above the entrance of the nerve roots from the affected part. By this operation the temperature sense is also abolished, but that is a small inconvenience if the patient is warned not to burn himself accidentally afterwards. Tactile sensibility is not interfered with.

To those who are not familiar with spinal surgery it may appear that this is an operation at least as severe as those which have been considered above. But actually it is not so. The removal of at most two or three laminæ in the dorsal region of the spine can be done with hardly any hæmorrhage and with the minimum of shock, even in an elderly patient, while the section of the cord is not necessarily attended with any serious risk. As compared with operations like arthrodesis and reconstruction of the hip, chordotomy is far less disturbing to the patient, while the results hitherto have been remarkable.

1. Man, aged 60. Fell on left hip three years ago; was not laid up, and had no treatment except rubbing with liniment. Hip has been painful and getting progressively worse ever since. Walks with a pronounced limp. Left great trochanter somewhat raised and prominent. Flexion of left hip limited to 40 degrees; rotation and abduction absent. Constant pain. X rays show advanced osteoarthritis of left hip. Operation, April 18th, 1929: chordotomy. Right spinothalamic tract divided at level of fifth dorsal vertebra. Result: complete loss of sensibility to pain up to level of left costal margin. Movements of left hip much increased and quite painless. Discharged May 18th, walking well.

2. Man, aged 40. History of contracted hips following typhoid 27 years ago. Has scar of old abscess over right great trochanter; otherwise right hip is apparently normal. Complains of gradual onset of pain and stiffness in left hip for five years. Is now in constant pain. Walks with pronounced limp. Left hip palpably enlarged; all movements very much restricted and painful. X rays show chronic arthritis with gross enlargement of head of left femur and acetabulum. Operation June 11th, 1929: chordotomy. Right spinothalamic tract divided at level

of fifth dorsal vertebra. Result: complete loss of sensibility to pain up to left costal margin. Left hip can be manipulated vigorously without pain. Movements much freer. Discharged July 10th, walking well.

Conclusions.

A great many people are going about in more or less constant pain and disability from osteoarthritis of the hips and other joints of the lower extremities. After spending a considerable part of their lives and fortunes in seeking relief from palliative treatment many of them seek surgical advice on account of the continued pain and disability. The forms of surgical intervention hitherto available—namely, arthrodesis and arthroplasty—are far too severe for most elderly patients, and it is usual to advise operation in such cases only when the pain is intolerable and something must be done. Chordotomy affords a means of giving immediate, complete, and permanent relief from pain in these cases without interfering with the hips or other joints.

It is not suggested that chordotomy is a trivial operation which can be lightly undertaken in all cases. But it is a much less severe operation than either arthrodesis or arthroplasty, and since it accomplishes the same object—namely, the relief of pain—more surely and with less risk, I venture to think that it may become the operation of choice in some of these cases.

Clinical and Laboratory Notes.

THE RELATION OF CAROTIN TO VITAMIN A.

By Thomas Moore, D.Sc.

(*From the Medical Research Council's Nutritional Laboratory, Cambridge.*)

In an earlier paper[1] in The Lancet I supported the claim of Euler, Euler, and Hellstrom,[2] that the pigment carotin, even after many recrystallisations, possesses physiological action similar to that of vitamin A. Duliere, Morton and Drummond,[3] using a fat-free basal diet, subsequently failed to confirm this view, but further investigations by the writer[4] and by Collison, Hume, MacLean and Smith,[5] in both of which basal diets containing fat were used, furnished a weight of evidence in favour of the intense activity of the pigment, even when in the purest form obtainable.

Notwithstanding such high activity, it has been obvious to all investigators that carotin cannot possibly be identified with the familiar form of vitamin A found in cod-liver oil. To reconcile the common physiological action of substances so different, Euler and his colleagues have suggested that vitamin A activity may not be the special property of any individual molecule, but may be possessed by several molecules of the carotinoid type. The factor present in cod-liver oil, for example, may well be a carotinoid derived from marine algæ, or possibly a hydrocarotinoid. On seeking support for this hypothesis, however, Euler, Euler, and Karrer[6] have found that out of numerous substances investigated—only carotin and dihydro-α-crocetin (a polybasic acid obtained by the reduction of crocetin, a pigment of saffron) possess growth-promoting power.

The case of dihydro-α-crocetin is surprising, and its discussion may well be postponed until confirmatory evidence has been put forward. With regard to carotin and vitamin A, however, my preliminary experiments, recorded below, have indicated the possibility that the pigment may not independently exert the same action as the vitamin, but that it may act as a precursor capable of giving rise to the vitamin in vivo.

Euler, Euler, and Karrer[7] have claimed that when carotin is administered to rats above a certain level it is stored in the liver unchanged. An examination of the liver fats of rats which had received excess of carotin has led the writer to a different conclusion. Albino rats (litter mates), employed in an experiment to demonstrate the absence of vitamin D in carotin, were placed upon the Steenbock rachitogenic diet No. 2965,[7] and were given daily graded doses of a sample of carotin (M.P. 174° in air), which had been prepared from carrots and recrystallised five times from chloroform by the methyl-alcohol method. At the conclusion of the experiment, which lasted 36 days, the livers were minced, digested with 5 per cent. caustic potash, and extracted with ether. The liver fats were obtained by washing, drying, and evaporating the ethereal extracts, and were analysed for carotin and for vitamin A by colorimetric and spectroscopic methods. The data obtained are shown in the Table.

Rat No. Maximum weight.	Daily dose of carotin (mg.).	Total colorimetric units ingested by rat.		Total colorimetric units found in liver.		Total yellow units to be expected in liver if blue chromogen were carotin.
		Blue units in $SbCl_3$ reagent at 590 μμ.	Yellow units in $CHCl_3$.	Blue units in $SbCl_3$ reagent at 610-30 μμ	Yellow units in $CHCl_3$.	
♀ 1 (114 g.)	Nil	Nil	Nil	100	11	1100
♂ 2 (126 g.)	0·0001	0·6	6·6	100	10	1100
♂ 3 (143 g.)	0·001	6	66	100	10	1100
♂ 4 (150 g.)	0·01	60	660	200	11	2200
♂ 5 (132 g.)	0·1	600	6,600	250	14	2750
♂ 6 (140 g.)	0·75	1500	19,500	550	45	6050

Attention may first be directed to the striking case of rat No. 6, which received carotin at the high level of 0·75 mg. daily. Although this amount of pigment, if absorbed unchanged, would have been sufficient to render the whole rat intensely yellow, it is noteworthy that on autopsy the body fat was found to be as colourless as that of control animals. Even in the liver fat only feeble yellow pigmentation was observed, but on the other hand an unusually intense reaction was given with the antimony trichloride reagent. Since the absorption band observed spectroscopically in the blue solution was situated at 610-630 μμ (characteristic of vitamin A) and not at 590 μμ (characteristic of carotin), strong evidence was afforded that a proportion of the pigment had been transformed in vivo to vitamin A.

This possibility is supported by the other results obtained. The colorimetric units adopted represent those amounts of material which when dissolved in a cube of 1 cm. side of either chloroform or the antimony trichloride reagent would produce colorations equivalent in depth to 1·0 Lovibond unit (yellow or blue respectively), when viewed through the cube. 1 mg. of carotin under these conditions contains 1800 yellow or 165 blue units. It will be seen at once that in the case of Nos. 2 and 3, to which carotin was administered at less than the minimal physiological dosage, no opportunity for storage was afforded, and the blue unit contents of the livers of these rats did not rise above the level of the negative control rat No. 1. In the case of all three rats (Nos. 4, 5, and 6), which received carotin in excess of the minimal dose, decidedly higher values in blue units were observed, but no appreciable increases in yellow units, such as must inevitably have accompanied the storage of carotin, were observed. This evidence, considered in conjunction with spectroscopic data, makes it plain that the high values in blue units shown in these cases were due to vitamin A.

The above experiments indicate clearly that carotin does not appear unchanged in the liver of the rat in more than minute traces, even when large excess of the pigment is ingested. A strong temptation must exist to connect the disappearance of the pigment with the formation of the vitamin. This important question is being put to test in more extensive experiments in which it is hoped that dangers due to irregularities in storage, or complications arising through the conservation of the rat's original store of vitamin by the preferential use of the added carotin, &c., may be ruled out. For the present justification must exist to suspect all estimations of carotin which are based purely on data obtained by the use of the antimony trichloride reagent without the support of spectroscopic data and estimations of yellow pigmentation.

Conclusion.

The ingestion of excess of carotin by the albino rat leads to no increase of the pigment in the liver, but to a great intensification of the colour reaction for vitamin A.

A CASE OF "POST-VACCINAL ENCEPHALITIS."

BY G. N. GROSE, M.R.C.S. ENG.,
HOUSE PHYSICIAN, ST. GEORGE'S HOSPITAL.

THE following is an account of a fatal case of encephalitis following vaccination recently admitted to St. George's Hospital:—

The patient, a boy of 14, passed the medical examination for the Post Office service in June of this year. He was vaccinated for the first time on July 30th; Government calf lymph was used but no other person was vaccinated at the same time. Four insertions were made, three of which "took well." His doctor examined him on August 8th and found the vaccination to be pursuing its normal course. The boy's father says that on the 9th he complained of headache and was constipated. Stiff neck and pain in the chest on deep respiration followed and continued for two days. On the 12th the headache was much worse. He became drowsy and this drowsiness increased till his admission to St. George's Hospital the same evening.

On admission the temperature was 103·4° F., the pulse-rate 104, and the respiration-rate 30. The boy was flushed and the whole body surface felt hot and dry. He was very drowsy and made no attempt to understand or answer questions. He opened his eyes from time to time, groaned faintly, rolled his head from side to side, and appeared to resent examination. There was no head retraction but definite stiffness was present in the neck muscles and erector spinæ. The pupils were equal in size, partly dilated, and reacted briskly to light. The fundi appeared normal but the discs were slightly inflamed.

The upper limbs were held in an attitude of flexion with occasional spasmodic movements and muscular twitchings. Both limbs were spastic and all tendon reflexes were greatly exaggerated. *The lower limbs were flaccid*, the right more than the left. Tendon reflexes were only feebly present. Plantar responses on both sides were equivocal. Kernig's sign was present on both sides. The abdomen was retracted and slightly resistant. Reflexes were present. There was no bladder distension and neither liver nor spleen was palpable. The heart was slightly dilated and a soft blowing systolic murmur was audible all over the præcordium. Nothing abnormal was detected in the lungs.

Vaccination marks were present on the left upper arm and appeared to be normal; of these three had "taken" and were surrounded by some petechial hæmorrhages.

The cerebro-spinal fluid on admission was *under moderate pressure* and clear. Dr. E. L. Hunt's report on it was as follows: "Colourless fluid; marked excess of cells in centrifugalised deposit, polymorphs about 80 to 90 per cent. No organisms found; globulin—no excess; albumin—excess, opaque cloud; sugar—well-marked reduction, about normal = 0·085 per cent."

Course of the Illness.—On August 13th drowsiness had advanced to coma. Pupils were still equal and active and there was no squint. Fine fibrillary twitchings were visible from time to time in both masseter muscles. There was complete flaccid paralysis of the right leg. In the left leg only the knee-jerk could be elicited and on attempting to obtain a plantar reflex the whole limb was drawn up slowly. The abdominal reflexes were present only in the upper right quadrant. The cremasteric reflex was absent. The bladder was distended and there was slight incontinence of urine. Urine drawn off by catheter contained nothing abnormal. The temperature rose to 106·5° F. at night and the respiration-rate to 36. There were no physical signs in the lungs. The resting blood-sugar was 0·188 per cent., and the blood-urea 0·037 per cent.

At a second lumbar puncture the fluid was found to be under less pressure than previously. Dr. R. B. Hervey Wyatt reported that it was "slightly tinted and blood-stained fluid. Sugar present in normal amount; globulin—faint haze; albumin—slight excess. Excess of cells—chiefly polymorphs; many lymphocytes also present; no organisms seen."

On August 14th the coma was deeper. The temperature fell during the day from 106° to 103°. The patient had incontinence of fæces but not of urine. There was complete flaccid paralysis of both lower limbs and the upper limbs were less spastic. Pupils were still equal and reacted to light but were smaller; there was no squint. The neck muscles and erector spinæ were less stiff. A hard, red swelling, size of a tangerine orange, appeared over the left sacro-iliac joint. Several erythematous patches were also present on other parts of the body. No hæmorrhages were seen in the buccal mucous membrane or fundi. Considerable œdema of the prepuce appeared. Respirations became slow and sighing at night.

At a third lumbar puncture the fluid was under greater pressure than on August 12th and more deeply blood-stained. Dr. Hunt reported: "Fluid contains a little *macroscopic* blood. After centrifuging the fluid the supernatant fluid has a distinct faint yellow colour. Centrifugalised deposit—mostly blood; the leucocytes present do not seem more numerous than would be accounted for by the blood present; the percentage of lymphocytes is rather high. No organisms found. Sugar—present, about normal; globulin—no excess; albumin—excess, opaque cloud. Urea = 0·06 per cent. No growths were obtained on any of the cultures made from the specimens of cerebro-spinal fluid.

On August 15th the boy was considerably weaker. Urine obtained by catheter contained a trace of albumin and blood. The pupils were contracted and fixed. The fourth lumbar puncture yielded only 1 c.cm. of blood-stained fluid not under pressure. A swab taken from the vaccination marks yielded no growth on culture. Blood culture was negative.

The boy grew rapidly weaker and died in the afternoon.

Post-mortem Appearances.—The body was examined 10 hours after death. Heart: some dilatation of both auricles; otherwise healthy. Lungs: a few petechial hæmorrhages under the visceral pleura on the left side and some degree of congestion at the bases of both lungs. Liver: slightly congested; otherwise healthy. Spleen: larger than normal and congested but soft. Kidneys healthy. Bladder distended with urine.

There was no flattening of the surface of the brain but all the vessels were intensely congested. On section the cut surface was at once covered with minute globules of blood oozing from the congested vessels. No hæmorrhages were apparent to the naked eye and there was no apparent increase of fluid in the ventricles. There was no meningitis. Sections of the pons, cortex, and basal ganglia are being prepared for microscopical examination.

I wish to express my thanks to Dr. C. B. Levick for permission to publish these notes, and to Dr. Hunt and Dr. Hervey Wyatt for their reports on the cerebro-spinal fluid.

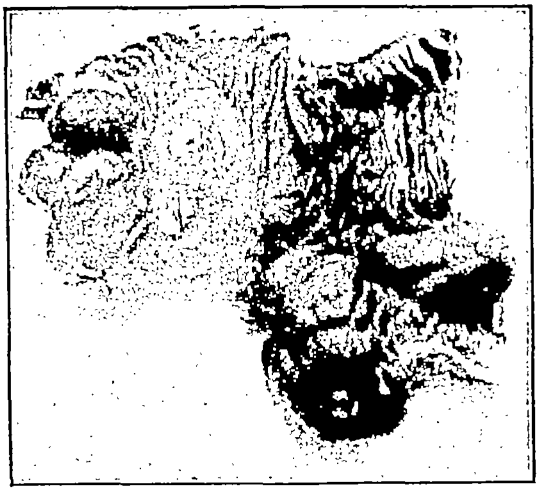
A CASE OF
INTUSSUSCEPTION CAUSED BY POLYPI
IN A YOUNG ADULT.

BY DONALD W. STUART, M.R.C.S. ENG.,
HOUSE SURGEON, ROYAL INFIRMARY, CARDIFF.

THE following case seems worthy of publication.

A girl, aged 15½, was admitted to the Cardiff Royal Infirmary on July 1st, 1929. On the same morning she had been seized with a sharp pain in the right side. During the course of the day she retched several times, but only vomited once; her bowels had been open on the previous day and she had never passed blood per rectum. She did not appear obviously ill. A definite, large, tender mass was palpable in the region of the umbilicus, and appeared to be of the consistency of intestine. There were no urinary symptoms or any undue emptiness in the right iliac fossa.

At operation by Mr. Harries the same evening a large ileo-ileal intussusception was found, and was reduced with great difficulty. Soft polypoid masses were felt within the lumen of the ileum. On opening the gut polypoid masses, like bunches of grapes, were seen springing from the wall and partially blocking the lumen; they extended along the wall for several inches, and the apex of the intussusception was opposite one of these masses. The photograph illustrates their appearance. As it was found impossible to remove the masses separately, about five inches of ileum was resected and the divided ends brought together with an end-to-end anastomosis. The patient made an uninterrupted recovery.



Polypoid masses springing from the wall of the ileum.

Microscopically, the protruding masses were shown to consist of fat lying in the muscular wall under the mucous membrane, and each had the appearance of an epiploic appendix projecting inwards.

It is quite common to get enlarged lymphoid follicles in an ileo-ileal intussusception, but very unusual to see an intussusception caused by polypoid masses.

I am indebted to Mr. D. J. Harries for permission to publish this case.

THE SURGICAL SIGNIFICANCE OF THE NERVUS SPINOSUS.

BY E. CAREW-SHAW, M.R.C.S. ENG.,
CLINICAL ASSISTANT TO THE NOSE, THROAT AND EAR DEPARTMENT, WESTMINSTER HOSPITAL.

THE nervus spinosus is so cavalierly treated in the standard anatomical and surgical text-books that it is not generally believed to possess the slightest surgical significance, yet it is an important path of referred pain—that reaction of a nerve to an abnormal stimulus. In this case the nerve is the mandibular division of the trigeminal, the abnormal stimulus is generally pressure and the result is pain over the area of supply of the nervus spinosus accompanied by tinnitus.

Anatomically the n. spinosus arises from the trunk of the third division of the trigeminal, and leaves the skull in company with the parent trunk through the foramen ovale. In this part of its course it is closely adherent to the periosteum at the base of the skull, and so usually escapes the notice of the dissector. It then re-enters the cranial cavity by way of the foramen spinosum with the middle meningeal artery, runs beneath the dura to the petro-squamal suture, and so enters the mastoid antrum, which it supplies, also sending twigs to the additus and posterior portion of the middle ear.

CASE 1.—A woman, aged 30, gave the following history. Three years ago there was pain and tenderness over the left ear which gradually increased in severity. Temperature 101° F., pulse-rate 120. Mastoiditis was diagnosed and treated by operation. The pain subsided for a few days after operation, only to reappear with marked vigour, and this time the right ear was also implicated. A sea voyage was tried, but there was no improvement. The patient's general condition deteriorated owing to the loss of sleep caused by the otalgia and tinnitus. On examination both drums were in perfect condition of colour, tension, and lack of scarring. The hearing showed the normal range of acuity. Behind the left ear was a well-healed mastoid scar. The nose, accessory sinuses, and throat were all normal and the teeth appeared to be in perfect condition. On X ray examination, however, bilateral impacted wisdom teeth were clearly visible. Further X ray plates showed that the roots of the impacted teeth were encroaching on the inferior dental canal. The two wisdoms were removed, also the first molars on both sides, because they exhibited signs of pressure necrosis; this gave almost instant relief from the pain and tinnitus.

CASE 2.—A nun, aged 32, had suffered from unilateral otalgia and tinnitus for six months. The symptoms were insidious in onset and though becoming steadily worse never interfered with sleep. The patient ascribed her troubles to a fall. On examination, the nose, throat, and ears were found to be quite healthy, but on the side of the painful ear an impacted wisdom tooth could be made out projecting a little above the gum margin. This was confirmed by X rays. The tooth and the one against which it was impacted—again because of pressure necrosis—were removed. This entirely cured all subjective symptoms.

CASE 3.—A woman of 29 gave a history of bilateral otalgia and tinnitus for nearly two years. Though there were occasional remissions, there were always exacerbations of pain at menstruation. Examination revealed nothing abnormal in the nose, nasopharynx, fauces, mouth, or larynx. Large painful glands could be palpated on either side of the neck. I regret to state that no radiographic examination was carried out because the patient, who was a dental student, assured me that she had had her mouth X rayed recently as she was worried about the condition of two crowned teeth, but that the plates showed nothing unusual. A blood count showed a leucocytosis of 16,000 with many immature polymorphonuclear leucocytes, but a very thorough medical examination failed to reveal signs of tuberculosis or other chronic disease. After two months the glands in the neck were no longer palpable, but the otalgia became steadily worse and with fewer remissions. The patient was again examined; this time a wisdom tooth could just be made out erupting slightly through the gum on the left side, but the X ray plates on which I now insisted showed that the tooth was impacted and also that a similar condition was present on the other side. The teeth were removed and the tinnitus immediately subsided, but the otalgia took nearly five weeks to disappear completely.

These three cases are selected from eight of their kind, and they all illustrate clearly how forgetfulness of the existence of this nerve might easily cause embarrassment or worse. I should mention that *each patient showed a rise of temperature to about* 100° F. with each exacerbation of pain.

OVERSEAS NURSING ASSOCIATION.—The annual report of this Association comes down to March 31st last. Its object is to supply trained nurses for hospital and private work in the Colonies and Dependencies, and among other British communities abroad. Its total income was £1144, of which £718 represented fees in respect of the cost of selecting 171 nurses for Colonial Governments and certain institutions. The number of nurses employed during the year was 840, an increase of 115. For the first time a nurse has been appointed for the Leper Settlement in Cyprus; she has charge of 98 Greeks and Turks.

HOSPITAL FOR SICK CHILDREN.—Last year, the annual report records, there were 6950 in-patients who cost £6 5s. 8*d*. each; new out-patients (6*s*. 10*d*. each) numbered 28,786. The board of management is still considering the urgent problem of reconstruction. Although the site of the Foundling Hospital is available it cannot be bought for lack of means, and unless those means are supplied, it is stated that the hospital will have to be rebuilt on the present disadvantageous site in Great Ormond-street. Since the institution was established in 1852, more than a million children have been treated.

BRITISH MEDICAL ASSOCIATION.

ANNUAL MEETING IN MANCHESTER.

(Continued from p. 337.)

SECTION OF SURGERY.

DIVERTICULITIS.

Opening Address.

WITH Prof. E. D. TELFORD, the President, in the chair, a discussion on Diverticulitis was opened by Dr. E. I. SPRIGGS (Ruthin). He began by reviewing the history of diverticulitis, and said that Graser in 1808 was apparently the first to suggest that inflammation of the peritoneum about the sigmoid colon was due to diverticula. With the advent of X rays further light was shed on the condition, and early stages of the disease detected; it appeared that there was a stage in the bowel in which diverticula were present but not inflamed. Afterwards O. A. Marxer detected a still earlier stage, so that three stages in the progress of the disease were now recognised: (1) the pre-diverticula stage; (2) the stage of formed diverticula; and (3) the stage of inflamed diverticula, or diverticulitis. In the first stage the affected bowel lost its normal segmentation and presented a more rigid outline due to pathological changes in the bowel wall. The second stage—i.e., of formed diverticula—was often discovered by radiological examination, and in 1000 such examinations at Ruthin Castle it was found in 10 per cent. As regards microscopic features, the muscular wall of the bowel might or might not cover the pouch. The ætiology of diverticulitis was not yet fully understood, but the incidence in middle age pointed to the pouches being acquired and not congenital. They might be simple pulsion pouches, but Dr. Spriggs thought the main feature was probably that of inflammation, for they were found associated with infective foci in other parts of the body. Constipation, he said, was probably not the cause, for the disease was commoner in men than in women, and there was no abnormal constipation in the series. Aperients were more likely to be harmful, by producing liquid fæces which by bacterial or chemical action damaged the bowel wall.

The clinical features might be classified as follows: (1) discomfort round the navel, or more especially in the left iliac fossa; (2) flatulence and a feeling of distension, often with constipation, irregularity of the bowels, diarrhœa, or a sense of incomplete evacuation. These symptoms might have intermissions of several weeks or longer. In some cases the bladder was implicated, with painful and frequent micturition. A sausage-shaped tumour was sometimes felt in the left iliac fossa. Rectal hæmorrhage was rare. The pathological features were those of chronic inflammation of the pelvic colon arising from one or more diverticula and spreading to the peritoneal coat. Later on abscesses might form in the inflamed area, and, in time, chronic inflammation might lead to a scirrhous narrowing of the bowel wall.

The main points in the diagnosis were the long history and the well-being of the patient in the interval of the symptoms. The absence of bleeding and mucus was against malignant disease, although both might occur in diverticulitis. Radiographic examination was the most positive aid to diagnosis, but it was a mistake to diagnose diverticulitis on the ground that some diverticula were seen, or to miss the condition because the affected piece of bowel was not thrown into profile. When there was a narrowing without the characteristic appearance of diverticulitis, the presence of near-by diverticula made it probable that the case was one of diverticulitis, though the possibility of cancer being also present was not excluded. Obstruction might develop in diverticulitis either from inflamed mucosal folds, this form of obstruction rapidly yielding to douching and warm oil enemas, or from fibrous constriction of the bowel wall. Douching might give relief in this as in the former.

The treatment of diverticulosis consisted in keeping the alimentary canal as clean as possible; any source of sepsis must be removed. Diet should be simple and regular with a good deal of fruit and vegetables and little meat. Dr. Spriggs used a freshly treated culture of *Bacillus acidophilus* in sterile milk. Paraffin was also given to ensure that the motions were soft. He did not believe in aperients except in special cases. The colon was to be washed out with normal saline solution every other day for a time; in some cases it was necessary to do this permanently. The above regulations, with a sufficiency of exercise and rest, together with abstinence from alcohol, was all that was necessary as a rule. Often by such treatment the disease could be arrested, or its progress at least greatly retarded, the pouches emptying their contents more rapidly after treatment. Operation might be needed for an accident such as the perforation of a pouch, also for complications such as an abscess or a fistula, and in some cases where obstruction had supervened. In a number of cases the disease was much localised, and some of them were favourable for excision.

Dr. Spriggs concluded his paper by saying that diverticulosis was a complaint that could be controlled if recognised early, but became dangerous if allowed to take its course unchecked. It was necessary, therefore, to be familiar with the early stages.

Dr. Mayo's Views.

Dr. WILLIAM J. MAYO (Rochester, U.S.A.) ascribed the first account of diverticulitis to Habershon in 1857. There were, Dr. Mayo said, two types of diverticula of the colon, the acquired and the true. In the former the mucous membrane of the intestine pouched through small openings at weak points of the bowel wall. This type was concerned in diverticulosis, in contra-distinction to true diverticula of the congenital type, in which all the intestinal coats covered the sac. Records at the Mayo Clinic, compiled from both radiographic and post-mortem evidence, suggested that more than 5 per cent. of persons over forty years of age had diverticulosis. A study of the relative incidence of diverticulosis in men and women showed 64 per cent. males and 36 per cent. females. As constipation was more common in women these figures seemed to show that this was not an important factor in causation. With rare exceptions diverticulitis was confined to the sigmoid. Cases might be classified into four groups: (1) Self-limiting diverticulitis in which there might be the formation of a tumour which disappeared in the course of a few weeks. (2) Diverticulitis and peridiverticulitis with abscess formation resulting in various fistulæ. (3) Diverticulitis complicated by an obstruction of the bowel. In acute cases this was due to infection and œdema, in chronic cases to hyperplasia and adhesions. (4) Carcinoma developing on a diverticulum. In such cases carcinoma might develop as a result of infection and irritation in diverticula, and this last group might comprise those cases in which colostomy had been performed many years previously, the patient eventually dying of carcinoma. The distinction between diverticulosis and carcinoma of the sigmoid could usually be demonstrated by radiological methods.

In acute cases, said Dr. Mayo, surgical treatment should usually be tentative; he had operated in 20·2 per cent. of diverticulitis cases. If there was abscess formation the pus should be evacuated and if more radical treatment appeared to be necessary it could be postponed. If acute obstruction resulted, colostomy should be performed, and at a subsequent operation the stenosed portion of the sigmoid and the colostomy opening might be excised simultaneously or cæcostomy might be done instead, with radical operation later if necessary. In other cases colostomy might be resorted to for temporary relief, the opening being closed later if the lumen of the colon spontaneously became patent. Other operative procedures were for the cure of fistulæ.

Discussing the origin of acquired diverticula, Dr. Mayo pointed out that the sigmoid colon, being of relatively recent development, had not achieved the stability of the primitive small intestine. It would be interesting to know whether diverticulitis was as common in the rice- and fish-eating countries as in potato- and red meat-eating countries, the latter articles of food tending to produce a large fæcal mass and a large amount of bacterial action. There was also a possibility that spasticity of the colon predisposed to the development of diverticulitis, whilst there might be sympathetic nerve derangement due to decreased sympathetic control of the bowel.

Medical and Surgical Treatment.

Prof. W. H. Maxwell Telling (Leeds) said he had published an account of his first case in 1908, and resummarised the known facts in 1917. He had originally made two mistakes: first, when he failed to invent the word diverticulosis to differentiate symptomless cases; and, secondly, when he said that the treatment of the condition could be summarised in the word surgery. He now believed in treating the case medically as long as possible unless there were complications, and he thought the prognosis not too gloomy. For treatment he recommended: (1) administration of liquid paraffin to keep the fæcal mass soft; (2) weekly lavage of the bowel by saline purges; (3) an ordinary diet, eliminating as far as possible indigestible things such as nuts, and also, preferably, potatoes; (4) the avoidance of any strenuous abdominal exercises so as to reduce the risk of perforation; and (5) the postponement of surgical intervention until absolutely necessary.

Mr. J. P. Lockhart-Mummery (London) disagreed with the statement of Dr. Spriggs that diverticula were formed as a result of pre-existing inflammation; he believed that the formation of diverticula was the first stage and that the inflammatory condition was secondary to their formation. Probably diverticula started as pulsion-herniæ of the mucous membrane of the colon, and secondary inflammation might take place at almost any stage in their development. Predisposing to their development, it seemed probable that there was degeneration of the bowel wall from age and unnatural conditions of bowel function. He distinguished two different types of diverticulitis: (1) a type in which the colon wall became inflamed over a wide area at an early stage of the pouches, this being the type in which obstruction occurred and could only be treated by resection of the damaged gut or colostomy; (2) a type in which the diverticula developed without the accompanying inflammation, such cases being rightly called diverticulosis. Inflammation might eventually occur in one or more of the diverticula and might result in abscess formation or peritonitis.

Diverticulitis was a disease of the wealthy classes. The diagnosis depended ultimately on radiography or discovery during laparotomy. The disease could, however, be diagnosed with considerable accuracy through the clinical picture, the chief symptoms being pain and tenderness of the left iliac fossa with slight rise of temperature. In women the affected portion of the colon might cause symptoms suggesting disease of the left Fallopian tube, and in men vesical symptoms. The early stages of diverticulitis could be successfully treated medically, and diverticulosis was a condition calling for no surgical interference; but once the inflammatory mischief was well established the condition was progressive, and although the condition might be kept in check for a considerable period serious results might occur quite suddenly. The best results of surgery were seen when the diseased area was confined to a short length of bowel and resection was performed. In many cases resection was impossible and colostomy the only procedure available. Colostomy was necessary when an abscess is perforated, either externally or into the bladder. In some cases the patient might be saved a colostomy by freeing the bladder and wrapping it carefully in omentum. Those cases in which septic sinuses had formed were very difficult to treat even when free drainage was established.

Mr. Lockhart-Mummery concluded by saying that he thought the association between diverticulitis and carcinoma of the colon was probably accidental in most cases, though possibly, through the pressure in the colon, a carcinomatous stricture might lead to the formation of diverticula.

Mr. Seymour Barling (Birmingham) said that, to the surgeon, diverticulitis most often presented itself as a local abscess, peritonitis, or intestinal obstruction, and treatment must be prompt and simple. Later on the problem of the underlying disease could be considered. It must be borne in mind, first, that the disease lay dormant, or progress was very slow and could be checked by suitable medical treatment; and, secondly, that the technical difficulties might make operation formidable. Nevertheless, in selected cases resection could be undertaken. From a chance observation of a case during a laparotomy he had noted that there was a stage at which the bowel wall was inflamed and irritable, when spasm could easily arise and cause the mucosa to protrude; and these two factors of inflammation and spasm appeared to be the essential underlying cause of the fully developed condition. He had never met with carcinoma developing on diverticulitis, but in two of his cases he had seen a stalked papillomatous growth associated with diverticulitis, and he did not regard the association as wholly a coincidence.

Mr. Garnett Wright (Manchester) called attention to emergencies such as free perforation into the peritoneum and fistulæ between colon and bladder due to inflammation in a single diverticulum. He gave a short account of a case he had operated on for acute intestinal obstruction, a colostomy being performed which was later closed because the inflammatory trouble in the colon had subsided, leaving a patent bowel.

Prof. D. P. D. Wilkie (Edinburgh) thought that a distinction should be drawn between diverticulosis and diverticulitis, the former being relatively common and unassociated with symptoms of ill-health. Surgeons might be consulted for: (1) Development of acute symptoms which generally subsided without operation. Occasionally immediate operation was necessary for diffuse or localised suppurative peritonitis showing that a perforation had occurred. (2) Intestinal obstruction for which a colostomy might be required. (3) A group in which the main features were a chronic toxæmia and in which coincident cholecystitis was often found, and probably represented a secondary infection. In these cases, owing to the poor operative risk, expectant lines of treatment were indicated. In a few cases resection was desirable. It should be done only after preliminary colostomy to allow the subsidence of inflammatory mischief; the bowel should then be resected with the colostomy.

Mr. T. P. Kilner showed a series of slides illustrating reconstructive surgery. First series showed methods of Thiersch grafting with pressure.

SECTION OF DISEASES OF CHILDREN.

CHRONIC DYSPEPSIA IN CHILDREN OF SCHOOL AGE.

With Dr. E. A. Saunders in the chair, a discussion on this subject was introduced by Prof. F. S. Langmead (London), who said that the term chronic dyspepsia in children was used to connote a group of symptoms varying in degree and in proportion, which together formed a common clinical picture. The picture presented was that of a dull and listless child, with a poor appetite and a coated tongue. There might be vague abdominal pains; the general nutrition was impaired and the stools irregular. Slight nocturnal fever, disturbed sleep, and psychical symptoms might also be present. In comparison with adult dyspepsia the difference lay chiefly in the relative infrequency of organic lesions in children. It was doubtful if it was justifiable to regard the so-called intestinal dyspepsia of children as a disorder apart from dyspepsia in adults.

Ætiology of Intestinal Dyspepsia.

Analysis of the symptoms showed that they fell into three groups—abdominal, constitutional, and psychical. The whole position of toxæmia—arising in that home of lost causes, the intestinal tract—was thorny and contentious; but neither toxæmia nor acidosis needed to be invoked to explain defective nutrition in a child with chronic digestive disorder.

(1) *Dietetic Causes.*—Food, said Dr. Langmead, played an important part. Some cases were associated with continued overfeeding; others with meals so frequent or irregular that appetite was absent. A child would always take its food if there was appetite, and there was no surer way to court dyspepsia than to eat when it was absent. Other common errors were giving cod-liver oil, &c., before meals, giving food at or near bed-time, food-bolting, and a diet containing excess of "roughage." Too much stress should not be laid upon the ætiological significance of any undigested particles found in the fæces. The relative excess of one of the elementary food factors was apt to be less considered in children of school age than in infants, but there was no doubt that faults in dieting were often committed along these lines. This was specially noticeable in the case of fat dyspepsia. The fermentation which arose from carbohydrate excess often led to the passage of frequent mucus-containing stools. There was also a group of cases which arose from protein sensitisation, producing nausea and vomiting very soon after the taking of food. Inquiry in such cases might elicit that the vomiting was always after a particular article of food—e.g., fish, eggs, apples,—and their omission would bring the attacks of vomiting to an end. The part played by vitamin deficiency in children of school age was doubtful. A cause which should always be considered was defective mastication.

(2) *The Rôle of Infection.*—To correlate the symptoms and course of the digestive disorder with the infection was not possible; nor could it be claimed with certainty that the departure from the usual intestinal flora was primary and provocative and not merely secondary and incidental. The production of the toxæmia was a difficult question and one worthy of discussion. It had often been shown that indicanuria was no guide to intestinal putrefaction, and probably stasis and putrefaction were not sources of intoxication so long as the mucosa was healthy. Focal sepsis, teeth, tonsils, adenoids, &c., did appear to play an influential part in some instances, but chronic appendicitis was probably not an important cause in many children.

(3) *Hepatic Dyspepsia.*—The cases which Dr. Langmead had been accustomed to call "hepatic" were those in which fats were badly borne, in which there were from time to time bouts of toxæmia, with pale greasy stools, slight jaundice, and sometimes a palpable liver. Defective functioning of the liver might, however, be a factor in many of the cases and might be related to toxic symptoms. The use of bile-salts certainly increased the power of these children to deal with fats. The changes found in the liver in fatal cases of cyclical vomiting seemed definitely to inculpate this viscus.

(4) *The Rôle of the Nervous System.*—Here the question that arose was whether the nervous symptoms were the result or the cause of the intestinal symptoms, or whether both were due to some antecedent cause. Dr. Langmead's view was that in most cases the nervous symptoms were secondary to the intestinal disorder.

In conclusion, he suggested that there was no fundamental difference between intestinal dyspepsia in children and many examples of dyspepsia in adults, and no reason for regarding it as a disease apart, with an individual ætiology.

Discussion.

Dr. HAZEL CHODAK GREGORY (London) was of opinion that the theory that the greater part of childish dyspepsia was due to hyperchlorhydria was based on a fallacy. With regard to the appendix it was doubtful if any inflammation or other abnormality of it was a common cause of intestinal indigestion. Among the organic lesions causing symptoms of dyspepsia tuberculous infection of the mesenteric glands was fairly common during school life, though the symptoms were by no means clearly defined. The present tendency to diagnose every case of dyspepsia in which there appeared to be a difficulty with fats, as one of acidosis was being overdone. A fat-free diet might suit for a week or so, but was quite inadequate for ordinary requirements. The common types of dyspepsia in childhood Dr. Gregory considered to be functional; they were sometimes hepatic, sometimes pancreatic, and sometimes enteric, but the system chiefly involved was the nervous system.

Mr. HERBERT RAYNER (Manchester) said that surgeons only saw those cases due to some tangible organic disease and these formed a very small class. The common organic lesions encountered in childhood were appendicitis, tuberculous mesenteric or retroperitoneal glands, tuberculous peritonitis, and a motley collection such as chronic intussusception, tuberculous ulcers of ileum, and Meckel's diverticulum. Gastric and duodenal ulcers were very rare indeed. Appendicitis as a cause of dyspepsia should not be overlooked, though as a rule the symptoms differed in many respects from those encountered in the adult. Three types of appendicitis could be recognised in childhood: (1) Cases with no previous history of any abdominal disorder. (2) Cases with a history of recurrent attacks of pain in the stomach over several years, but not recognisable as attacks of acute appendicitis; this was the commonest type. (3) Cases where the history indicated that the child had had mild attacks of appendicitis lasting from two to four days and recovering without operation. Tuberculous glands, said Mr. Rayner, were not so important from a surgical point of view, but there were some cases which it was impossible to distinguish from acute appendicitis.

Mr. T. S. IRWIN (Belfast) confined his remarks to the dyspepsia associated with duodenal ulcer, and gave details of four cases that had occurred in his own practice. His conclusions were (1) that duodenal ulcer did occur occasionally at school age; (2) that symptoms of a similar nature going back to school age were to be found in adults suffering from ulcer; (3) that even during school age some cases of actual perforation had been found; and (4) that vomiting was a much more frequent symptom in children than in adults.

Prof. C. W. VINING (Leeds) thought many dyspeptic symptoms were due to dietetic deficiencies. Protein deficiency and vitamin deficiency probably occurred in a large number of children. Good feeding and a generous diet were important prophylactic agents.

Dr. CATHERINE CHISHOLM (Manchester) had found that in over 3500 girls attending a secondary school in only 4·5 per cent. were gastro-intestinal symptoms present of sufficient severity to cause absence from school. It did not appear, therefore, that school stress, &c., played any part in the production of dyspepsia in children of school age, but defective hygiene was undoubtedly very important.

SECTION OF OPHTHALMOLOGY.

FOCAL SEPSIS AND DISEASES OF THE EYE.

Mr. J. GRAY CLEGG (Manchester) the President, opened the proceedings by brief reference to some former ophthalmic surgeons of Manchester: Benjamin Gibson, one of the most famous oculists of his day, who published in 1811 his treatise on the formation of an artificial pupil; David Little, a most skilful operator; Mules, whose name was associated with his operation for evisceration; and Hill Griffith, the first to recognise cellular deposit on the back of the cornea in choroiditis.

Mr. A. F. MACCALLAN (London) opened a discussion on toxic absorption due to focal septic lesions, and its effects in the production of eye diseases. He claimed that British ophthalmology was leading in the study of this subject, and acknowledged his indebtedness especially to the work of Mr. William Lang. The more usual sites of such focal sepsis were the mouth in adults and the tonsils in children. Less common sites were the appendix, colon, or duodenum, the gall-bladder, the female pelvic organs, and the deep urethra and vesiculæ seminales in the male. Any chronic focus of sepsis might set up ocular change—e.g., a septic focus in an old amputation stump. He disagreed entirely with the view expressed elsewhere, that dental sepsis did not cause ocular disease. In a suspected case it was important to obtain really good radiograms of the whole mouth. Edentulous areas should be radiographed, for buried stumps, or unerupted teeth might be found. The frequency of apical abscess was not yet realised by the medical profession. Pain might be absent, and the radiogram might furnish the only evidence. Pyorrhœa was, in his experience, a less common cause of ocular disease than apical abscess. Tartar on the teeth might also provide the focus of absorption. Crowned teeth were specially subject to the formation of apical abscesses. The resistance factor was extremely important; many people with septic foci had good powers of resistance, and so escaped ocular manifestations. The eye might be infected by three paths: (1) direct extension, from open dental sepsis, tonsils, nasal mucous membrane, or accessory nasal sinuses; (2) lymphatic absorption; (3) deglutition and absorption from the alimentary canal. Among the results of direct extension were blepharitis, acute and chronic tarsal cysts, some forms of conjunctivitis, phlyctenular conjunctivitis, episcleritis, corneal ulcer, dacryocystitis, and orbital cellulitis. Meibomian cysts were, in his experience, almost invariably associated with dental sepsis, in private as well as in hospital patients. Phlyctenular conjunctivitis in children was usually associated with enlarged tonsils. The treatment of ulceration of the cornea had been immensely improved in his hospital clinics since the recognition of the frequency of associated causative focal sepsis; almost every case showed the obvious presence of open dental sepsis, from which there was a constant flow of pyogenic organisms to the conjunctival sac. In acute ulceration of the cornea dental treatment must be prompt and adequate, within 24 hours, if it was to be effective.

Dendritic ulcer, in Mr. MacCallan's opinion, was peculiarly apt to be associated with dental sepsis. Dacryocystitis was, he believed, often caused by it, and required surgical intervention—since removal of the dental septic focus alone would not suffice. In these conditions, toxic absorption by the lymphatics was more commonly the cause than direct extension. Iritis, on the other hand, might result from either open or closed dental sepsis, or from tonsillitis or other forms of focal sepsis. Cyclitis, with or without iritis, usually had a similar origin. Early discovery and elimination of the septic focus was of great importance. More than one septic focus might be present. Hyperæmia of the retina at the macula, without other fundus changes, was very often present when toxic products had got into the circulation; degeneration followed if the toxæmia persisted. Vitreous opacities were always accompanied by long-standing focal sepsis. Cataract had been produced experimentally by certain toxic conditions; toxins in the blood might so affect the ciliary body as to cause alteration in the aqueous, leading in turn to damage to the epithelium of the lens capsule, allowing the entrance of substances causing cataract. He believed that long-continued focal sepsis (usually dental) was the most important cause of cataract. It was therefore of great importance to detect early slight opacities in the periphery of the lens, and search for the focus of septic absorption, and to eliminate the cause of the cataract. Progressive myopia in children was, in his experience, always associated with enlarged and septic tonsils, and primary glaucoma he had found in numerous cases to be associated with a fulminating focus of sepsis. Lastly, the effect of focal sepsis on intraocular operations was very marked—a fact which should be remembered not only as regards adults undergoing operation for cataract or glaucoma, but also in children with septic tonsils who required operation for lamellar cataract, &c. In conclusion, the speaker said that though he had not dealt with the subject exhaustively, the opinions he had expressed were based on personal experience.

Discussion.

Dr. A. F. **Hurst** (London) laid stress on the need for a definite system of investigation, for which team-work was necessary. He thought the term "stomatologist" more accurate than "dentist." It should be remembered that probably every dead tooth was a source of infection. It seemed absurd to send edentulous cases to a dentist; but it had been found in a number of such cases that there were areas of rarefying osteitis. It was essential to have really good radiograms of the sinuses, and then expert examination by a rhinologist, for an antrum might be full of pus without any localising symptoms. He had never found ocular infections in association with duodenal ulcer. In connexion with achlorhydria it should be remembered that hydrochloric acid had not only a digestive function, but was also an important antiseptic. In its absence one would expect to find increased sepsis in the intestine. Bacteriological examination of the fæces was helpful if some definitely pathogenic organism was found—e.g., of dysentery—which ought not to be there. Leucorrhœa was of far more importance in this connexion than the average gynæcologist realised. When due to cervicitis it might be of great significance. It was important to realise that the cervix could be sterilised by diathermy. He had seen cases of arthritis cured by diathermy to the cervix—rather than to the joints. It was very useful and a great safeguard in some cases to have a vaccine prepared from the source of infection—e.g., in the mouth—and give some doses of this before offending teeth were extracted.

Mr. E. **Musgrave Woodman** (Birmingham) referred especially to the sphenoidal and ethmoidal sinuses as possible sources of septic absorption, and called attention to the close proximity of the optic nerve. X rays showed very little of the condition of these sinuses. Methods of investigation at present available were inadequate. These sinuses lay in the position of greatest danger not only to the eye, but to the body. He submitted that there was still a case for further investigation into this area. The technique devised by Dr. P. Watson-Williams was accurate for the sphenoidal sinus, but not so satisfactory for the investigation of the ethmoidal cells.

Dr. **Arnold Renshaw** (Manchester) brought forward figures embodying the results of examinations of 1269 cases of infective eye disease in the pathological department of the Manchester Royal Eye Hospital. Of these, 682 were syphilitic and 587 non-syphilitic. In 170 of these cases elaborate systematic examination had been made including the Wassermann reaction, the Pirquet test (human and bovine), temperature reactions after injection of tuberculin, renal efficiency, glucose tolerance, and estimates of blood calcium. Of these 170 cases, syphilis was found in 41, tuberculosis in 47, tuberculosis with complications in 55, and other causes of infection in 20. Further analysis of the sources of infection (other than tubercle and syphilis) gave the following results: nose 44 cases, tonsils 38, teeth 24, ears 3, urine 6, cervix uteri 6, fæces 2, urethra (male) 2. In his experience, cases of tuberculosis affecting the eye did fairly well if treated with the proper tuberculin. Many of the cases were due to the bovine strain. Incorrect dosage might aggravate such cases. In people with oral infection teeth should never be removed till a vaccine had been prepared.

Mr. E. E. **Maddox** (Bournemouth) pointed out that dental sepsis, present in a patient with ocular disease, was not necessarily the causative factor. He referred to the interesting analogy in the structure of teeth and eyes—the enamel corresponding to the lens, the dentine to the sclera. Dental sepsis should not be regarded as a special entity; it was only a local expression of a general condition. Even a detached retina might sometimes be absolutely cured by the removal of septic teeth. He had had such a case in a young woman of 18 with double detachment of the retina. He attached importance to the least sign of rocking of a tooth when examining for suspicious teeth. Nearly all cataracts were due to focal sepsis somewhere

Mr. E. J. PRIMROSE (Glasgow) supported the views advocated by the opener of the discussion. He had had special experience of syphilitic diseases of the eye. In these cases antisyphilitic treatment was not all that was necessary. Other conditions often called for treatment at the same time—possibly some factor that had caused a latent syphilitic infection to become active or was hindering recovery. Or there might be a hypothyroid condition present, and recovery would be delayed till this was remedied.

Mr. W. B. INGLIS POLLOCK (Glasgow) urged the importance of examining the teeth before operation for glaucoma or cataract. He had seen three cases in which impacted unerupted teeth had been the cause of ocular trouble. It was advisable to remove a blind eye that might be a possible source of septic infection of the other eye. In private practice the expense of such elaborate investigations as had been described was a difficulty.

Dr. PATRICK WATSON-WILLIAMS (Bristol) said that in this matter ophthalmology was in advance of other sections of the profession. Only by all-round survey could one get to the bottom of these cases. He had suggested formerly the analogy between detachment of the retina and an infective pleurisy. He wished to emphasise the important factor of tissue defence. Defence failed at times owing to constant reinfection.

Mr. A. W. ORMOND (London) said that bacterial infection acted by chemical means; colloid chemistry was still in its infancy. Mr. Maddox's case of detached retina had interested him particularly. He had a similar case, in which cervicitis seemed to be the probable source of septic absorption. Dendritic ulcer had not seemed, in his experience, to be due to dental sepsis.

Mr. H. L. G. LEASK (Glasgow) referred to the fact that some rhinologists were more conservative than others. In his experience the ophthalmologist got more valuable help from those of the more daring temper.

Mr. T. AUBREY JONES (Stoke) called attention to McDonagh's work. He had had some very interesting results from using his treatment.

Mr. T. O. GRAVES (Birmingham) also referred to non-specific protein therapy—by T.A.B. vaccine. For example, where some chronic headache remained after a sinus affection this treatment stirred up an acute reaction, and the chronic headache disappeared.

Mr. N. BISHOP HARMAN (London) called attention to the curious fact that 75 per cent. of the phlyctenular lesions in children were located in the lower outer quadrant of the eye. In intractable cases of phlyctenular lesions it was remarkable how often removal of the tonsils effected a cure. In regard to detached retina, his experience confirmed the view that in some cases it was associated with dental sepsis.

Mr. MACCALLAN, in replying to the discussion, said, in regard to dendritic ulcer, there had, in his experience, recently been some focus of sepsis in all cases. In the removal of septic teeth caution was called for. Removal of a number of such teeth at one sitting sometimes had a bad effect. Such patients should be treated as cases of major operations were, they should have a general anæsthetic and go to bed for ten days. By this method untoward results could be avoided. As to vaccine treatment, he was not quite in agreement with Dr. Hurst. In cases of retinal thrombosis, he regarded vaccine treatment as likely to be specially dangerous. In cases of detached retina he now always looked for a focus of sepsis, and rarely used operative treatment for the detachment; the ætiology was probably similar to that of infective pleurisy. In ascertaining the presence of any dead teeth, the electrical testing of their vitality by the dentist was perhaps of more importance than a good radiogram. Before operating for cataract he would always remove a blind shrunken eyeball if present. He quite agreed with Mr. Primrose that it was important in syphilitic cases to look for other foci of sepsis.

SECTION OF OBSTETRICS AND GYNÆCOLOGY.

PLACENTA PRÆVIA.

AT a meeting of this Section, with Dr. C. E. DOUGLAS in the chair, a paper on

The Symptoms and Diagnosis of Placenta Prævia

was read by Dr. BETHEL SOLOMONS (Dublin). The terms "unavoidable hæmorrhage" and "placenta prævia" were used, he said, only when bleeding in the last three months of pregnancy was caused by the separation of a placenta situated either wholly or in part in the lower uterine segment. When speaking of the varieties of location he referred to placenta prævia as (1) central or total; (2) partial, where internal os was partially covered; and (3) lateral, where the edge could be felt just above the internal os in the lower segment. Use of the term "marginal" should be discontinued. As regards ætiology, he thought there must be some fault in the endometrium. He had several times curetted the uterus two months after the occurrence of placenta prævia, and had found evidence of either a true endometritis or else a hyperplastic condition of the uterine mucosa; he suggested that curettage was indicated two months after delivery in order to avoid a similar complication in future pregnancies. The dangers of placenta prævia, as shown by world statistics, were great for the mother and very great for the child. The mother might die from collapse following hæmorrhage, whilst sepsis might later develop owing to the low position of the placenta and the exsanguinated condition of the patient. Menorrhagia, the tendency to abort, and sterility were also sequelæ to be borne in mind. The records of the Rotunda Hospital showed 320 cases of placenta prævia with 10 deaths among 60,180 delivered; with improved technique in diagnosis and treatment Dr. Solomons was able to report a series of 55 cases without a death. Most of the babies were premature and only 12 were born alive. Placenta prævia should be suspected in pregnancy by the history of hæmorrhages at various times from the fourth month onwards. The first symptom to which attention was drawn was fresh hæmorrhage accompanied by clots. A very important point in diagnosis was that the bleeding was extremely insidious in its onset. There was no concomitant pain. Two pints of submammary saline should be given immediately after the hæmorrhage, and every practitioner should carry the apparatus and material for doing this. At the Rotunda Hospital the stock saline solution was made by boiling two teaspoonfuls of salt in a pint of water; when the solution was to be used one pint of boiling water was added. This gave the correct strength, and approximately the correct temperature (100° F.). After injecting fluid the abdomen should be examined. The uterus would be found soft and painless, with the presenting part high up and unfixed, and a uterine souffle would be heard in the hypogastrium. A vaginal examination should always be made and carried out with elaborate asepsis. The cervix would be found closed, and there would be bogginess in one or all of the fornices. If the os was open the placenta itself would be felt. The urine should be examined in all cases and would probably be found normal. In conclusion, Dr. Solomons pointed out that the prognosis depended on diagnostic ability and choice of therapeutic technique.

Treatment.

Dr. F. H. LACEY (Manchester) said that in face of a history of slight hæmorrhage at the sixth or seventh month, followed by perhaps another within several weeks, it was often hard to decide whether to temporise in the hope that the child might have a favourable chance. Since the child in these cases was usually born prematurely even when there had been no intervention, and the proportion of stillbirths was very high, the treatment adopted should be that which gave the best maternal results. If there was a history of severe hæmorrhage or of recurring slight hæmorrhages the uterus should be evacuated when the mother was in good condition. At St. Mary's Hospitals, Manchester, during the last ten years there had been 562 cases, of which 19·2 per cent. were primiparæ; the multiparæ had had an average of 4·9 children. The methods of treatment adopted were: (1) rupture of membranes in 125 cases, with a maternal mortality of 2·3 per cent. and 45 per cent. of stillbirths; (2) delivery by natural forces in 76 cases, with a maternal mortality of 2·0 per cent. and 30 per cent. of stillbirths; (3) version in 273 cases, with a maternal mortality of 7·6 per cent. and 81 per cent. of stillbirths; (4) breech delivery in 21 cases, with no maternal deaths; (5) Cæsarean section in 33 cases; (6) induction of labour in 15 cases, with no maternal deaths and 70 per cent. of stillbirths; (7) application of vulsellum forceps with weight (Willett's method modified) in 11 cases, with no maternal deaths and 27 per cent. of stillbirths. Dr. Lacey pleaded for more frequent Cæsarean section for placenta prævia at or near full term when the os was closed with a centrally placed placenta in an elderly primipara. In conclusion, he pointed out that of the 562 cases 28 had ended fatally. Fifteen per cent. had been treated at home for hæmorrhage and were very weak when admitted to hospital; this showed how important it was that every woman suffering from hæmorrhage during pregnancy, however slight, should be admitted immediately to a nursing home or hospital where she could be under constant supervision.

Discussion.

Prof. G. E. ESSEN-MOLLER (Lund, Sweden) was called upon to open the general discussion. He said that in placenta prævia the ratio of risk to the child was considerably greater than that for the mother, and he thought that in treatment maternal benefit should be aimed at. He agreed with the plea for the increased use and adoption of Cæsarean section for this condition.

Dr. J. W. RIDDEL (Plymouth) did not see why a simple issue should be complicated. Version gave the worst results and Cæsarean section was the operation of choice near full term.

Mr. L. C. RIVETT (London) agreed with the nomenclature of Dr. Solomons, and thought that the term "marginal placenta prævia" should be dropped. Discussing the differential diagnosis, Mr. Rivett pointed out that with accidental hæmorrhage the bleeding was continuous, whilst in placenta prævia there were repeated "shows" with periods of no bleeding in between. He thought that most cases delivered themselves with the aid of some simple procedure such as rupture of the membranes or the application of Willett's forceps; for the other cases he advised Cæsarean section. What was most important, however, was to avoid delay, for this was fatal.

Dr. A. L. MUDALIAR (Madras) considered that the degree of dilatation of the cervix should be stated in describing a case of central placenta prævia. The only sure way of diagnosing the condition was to feel placental tissue; in cases of high placenta prævia, although the placenta was not actually palpable, a peculiar gritty sensation could be made out if the finger were passed up through the cervix between the uterine wall and membranes. In the treatment Dr. Mudaliar considered small doses of pituitrin useful. Cæsarean section should not be done too frequently, and must only be considered when the child was alive and when there was a reasonable chance of its surviving. The mother could be saved by simpler methods.

Dr. J. P. HEDLEY (London) did not approve of the routine adoption of Cæsarean section for placenta prævia in young women. He pointed out that the patient had to be constantly watched and was in constant fear throughout subsequent pregnancies.

Prof. R. W. JOHNSTONE (Edinburgh) said that the importance of the diagnosis prompted the Edinburgh school to examine all patients thoroughly per vaginam; they did not hesitate to resort to anæsthesia and pass the finger up into the uterus to feel for placenta. No one should temporise with placenta prævia; treatment must be immediate.

Dr. GIBBON FITZGIBBON (Dublin) thought that although Cæsarean section had a place in treatment, statistics tended rather to over-rate its utility. He referred to over 200 cases treated in the Rotunda Hospital under his Mastership in which version was employed with a very low maternal mortality. Dr. FitzGibbon thought that treatment should follow vaginal examination. There was no great urgency in all cases, and it was better to delay examination until treatment could be undertaken.

Dr. GILBERT STRACHAN (Cardiff) maintained that in many cases of placenta prævia there was a great deal of shock. He agreed that immediate saline infusion was desirable.

Dr. R. S. STATHAM (Bristol) protested against the use of submammary saline; he had lately seen two cases of sloughing of the breasts as a result of it, and he now used the flanks for saline infusion. Hot vaginal douches were pernicious. The cases should be dealt with where and when the hæmorrhage occurred, and version therefore had a useful place in treatment. He used Willett's forceps and had found de Ribes's bag of value in cases where there was a good deal of shock and the recovery of the patient had to be waited for.

Miss MARGARET BASDEN (London) said she had employed vaginal plugging with gauze soaked in Bonney's paint after rupturing the membranes; this treatment, however, had been followed by superficial ulceration of the vagina and subsequent stenosis necessitating a plastic operation. She thought that the results were good as far as the mother was concerned. She employed Cæsarean section in bad cases.

Prof. W. BLAIR BELL (Liverpool) said it was impossible to adopt uniform treatment for every case. He thought the terms "placenta prævia centralis" (p.p.c.) and "placenta prævia partialis" (p.p.p.) should be employed, the former to include all cases in which there was encroachment of the maternal os by the placenta. In certain cases Cæsarean section was the only proper treatment—e.g., with central placenta prævia in a primigravida with undilated cervix and a viable child. Of the other cases a considerable percentage could be treated by Cæsarean section. While in cases of doubt the mother's life should be the first consideration, that of the infant could often be saved without extra maternal risk. He had had two cases of post-partum hæmorrhage after Cæsarean section for placenta prævia, and suggested that this accident might be avoided by the use of pituitrin and ergotin. It should be remembered that many cases, especially where the cervix was not involved, terminated normally.

Dr. W. R. ADDIS (Manchester) said that if treatment was to be carried out at home simple methods should be devised, and any attempt at increasing the number of instruments which the general practitioner had to carry was to be deprecated. He favoured either version or rupture of the membranes, together with administration of pituitrin.

Prof. DANIEL DOUGAL (Manchester) thought that "safety first for the mother" should be the obstetrician's motto when treating placenta prævia. The high fœtal mortality was due to (1) prematurity, and (2) separation of part of the placenta, and these should be considered carefully before any new form of treatment was introduced with the idea of saving the child. *Willett's forceps ought to be employed* more often. Prof. Dougal thought that the indications for Cæsarean section in cases of placenta prævia were definite and limited. It should be done only when there were chances of getting a live child.

Dr. H. L. H. GREER (Belfast) agreed with those who advocated caution before performing Cæsarean section. He always did an external version as a preliminary to bringing down a leg in cases of placenta prævia, so that the foot was over the internal os.

Sir EWEN MACLEAN (Cardiff) thought early version with slow extraction was the ideal. It was his own practice to exhaust all methods of treatment before resorting to Cæsarean section, and he asked whether the Cæsarean scar might not possibly be an ætiological factor for placenta prævia. He had one case of death from post-partum hæmorrhage following a Cæsarean section for placenta prævia. He agreed with Prof. Blair Bell about considering the child's life in deciding upon any form of treatment.

Dr. E. A. GERRARD (Manchester) urged that therapeutic methods favourable to the child should be preferred so long as the safety of the mother was not prejudiced. The partial type of placenta prævia seemed to offer most scope for improved methods. A form of treatment which involved little interference with the child and one which was nearest to the normal course of labour should prove the most satisfactory. These conditions, in his opinion, were fulfilled by Willett's method of rupturing the membranes and applying traction to the child's head by means of a forceps attached to the scalp.

The CHAIRMAN regretted that no general practitioner had spoken. He had been in practice for 47 years and had met with only nine cases of placenta prævia.

Reviews and Notices of Books.

SCIENCE AND PERSONALITY.

By WILLIAM BROWN, M.A., M.D. Oxf., D.Sc. Lond. With a foreword by Sir OLIVER LODGE. London: Humphrey Milford, Oxford University Press. 1929. Pp. 258. 12*s.* 6*d.*

IN a brief foreword Sir Oliver Lodge remarks with some surprise the versatility of the author, particularly his mathematical equipment. But Dr. William Brown has always shown in his writings the catholicity of his mind, and in addition a certain yearning for the religious and the philosophical. Unfortunately, his desire to be fair to psychology and yet keep intact his and other people's religious aspirations leads to a timidity in both acceptance and criticism. This is unfortunate in a writer who, in addition to wishing to keep abreast of advances in psychopathology, attempts to give philosophical sanction to his standpoint. One has always been led to believe that the best philosophers were, in their search for truth, dignified and logically uncompromising. It is this intellectual asceticism and austerity which is lacking in Dr. Brown's latest collection of essays. He covers the whole field of the sciences from mathematics to the normative studies of ethics and æsthetics; rightly so, since his thesis is that man's highest pursuits are the Good, the True, and the Beautiful. But in all fields he has left us vague as to what his point of view really is. He expresses very honestly his doubts about Freudian psychopathology, and makes pregnant remarks throughout his inquiry. That done, the more positive side is stated in somewhat cloudy philosophical announcements which are zealous rather than logically convincing. In this volume the author confesses a more than passing interest in the phenomena of psychical research. No psychologist has the right to ignore or to sneer at these phenomena; they call for calm and dispassionate inquiry. Dr. Brown is impressed by the data of so-called telepathic and mediumistic experiences. He gives us a sample which, however, more mundane explanations might suffice to elucidate. We should welcome from Dr. Brown an exposition of these phenomena by methods of research on the lines of his now classical work on the Essentials of Mental Measurement.

SYNOPSIS OF MIDWIFERY AND GYNÆCOLOGY.

Fourth edition. By ALECK W. BOURNE, B.A., M.B., B.Ch. Camb., F.R.C.S. Eng., Senior Obstetric Surgeon, Queen Charlotte's Hospital, London; Obstetric Surgeon to Out-patients, St. Mary's Hospital. *Bristol*: John Wright and Sons, Ltd. 1929. Pp. 434. 15*s.*

THE fourth edition of this book has been revised and brought up to date by the inclusion of such new matter as has been accepted as a permanent addition to our knowledge of obstetrics and gynæcology; it serves admirably as a supplement to and a substitute for the ordinary text-books for the purpose of revision before examination. One section only, in our view, deserves criticism, that on abdominal palpation. On page 26, when abdominal examination during pregnancy is described, two "grips" are advised. The next time that abdominal palpation is mentioned is in connexion with the diagnosis of occipito-posterior positions (page 93), when three "grips" are mentioned. On page 99 four "grips" are enjoined for diagnosis of face presentations and a similar number for breech on page 106, while little indication is given as to what the third and fourth grips are. This is of no moment to the experienced graduate, who sooner or later invents a method of palpation of his own, but is liable to confuse the beginners who use the book. Moreover, examiners in practical work are liable to demand precise and accurate knowledge of this important method of diagnosis. We question whether the method described on page 26, of attempting to push the head downwards and backwards into the pelvic brim by abdominal palpation alone, is really of much value, and in inexperienced hands it may well create a false sense of security. A fuller account might have been given of the modern views on the origin of pelvic endometriomata.

We know of no synopsis which better serves the purpose for which it is intended, and the book deserves the popularity it has attained.

LES OTITES MOYENNES.

By GEORGES PORTMANN, Professor to the Oto-Rhino-Laryngological Clinic in the University of Bordeaux; and KARL KISTLER, of Zurich, formerly *Assistant* in the Clinic. Paris: Masson et Cie. 1929. Pp. 212. Fr.70.

THE classifications of affections of the middle ear, for long purely empirical, has been put on a scientific basis by the pathological work of F. von Bezold and his pupils, F. Siebermann and A. Scheibe. But, although 30 years have elapsed since the publication of the first and only edition of von Bezold's treatise on diseases of the ear, the authors affirm that only a faint echo of his work is to be perceived in the literature of French otologists, and this book has been written to fill this gap. For the sake of accurate terminology, in this book the expressions "catarrh" and "catarrhal" have been avoided, since though they should denote inflammation of a mucous membrane, they are often used to designate very different affections. The termination "itis" expresses the idea of an inflammatory process, and therefore the expression cicatricial otitis, for a condition which is not such a process but rather the result of one, is ruled out. Again, otorrhœa is not the name of a disease, but of a symptom. These may seem small points, but the authors consider accurate nomenclature important as an aid to the classification of our conception of diseases of the ear, which is the chief aim of their work. The term "tubal obstruction" is here used to define the class of case often described as "acute catarrhal otitis," but distinguished from true inflammation of the middle ear by the absence of pain and the complete return of hearing after inflation; "tubal obstruction with exudation" takes the place of "chronic exudative middle-ear catarrh"; and chronic dry or adhesive catarrh is classified either as "tubal obstruction with persistent retraction of atrophied drum-membrane," or as a sequel of "recurrent simple otitis," or of "necrosing acute otitis." The book is written in a concise, almost tabular form, but contains much interesting matter. In regard to chronic suppurative otitis, a distinction is made between simple and cholesteatomatous; the former, which constitutes between 60 and 70 per cent. of all cases of suppuration, is characterised by a central perforation and a non-fœtid discharge, the latter by a marginal epitympanic perforation and a fœtid discharge.

The authors do not admit the conception that chronic suppuration depends on osseous lesions, since all the true bony lesions are consecutive to cholesteatoma; in support of their view they point out that all cases of death due to chronic suppurative middle-ear disease have shown an epitympanic perforation, and have been complicated by cholesteatoma and, that over a period of years in the Central European countries they have been unable to discover a single death due to chronic middle-ear suppuration with a central tympanic perforation. This last statement is supported by statistics collected by Bezold, Siebermann, and Scheibe, which show 11,105 cases of "simple" chronic suppuration with tympanic perforation and no death, contrasted with 4281 cases of "cholesteatomatous" chronic suppuration with epitympanic perforation and 78 deaths.

The book is profusely illustrated by microphotographs, some from the authors' collection and some from those of colleagues, among whom we notice Mr. J. G. Fraser of Edinburgh. These are beautifully reproduced, and add greatly to the value of the work, which is of importance to general physicians as well as to otologists.

Kolle and Wassermann's Bacteriology.

Handbuch der pathologen Mikroorganismen. Third edition. Edited by W. Kolle, R. Krass, and P. Uhlenhuth. Lieferung 18. Band V. S. 525–1036. Berlin: Gustav Fischer and Urban and Schwarzenberg. 1928. M.38.

This standard text-book on pathogenic bacteria needs no introduction, since it has been in international use as one of the works of reference for many years. The authors of this section have made no attempt to adopt any of the new nomenclatures of bacteria, such as that adopted by the American Society of Bacteriologists, but have been content to follow the time-honoured terminology. The volume opens with an account of the immunological aspects of *B. diphtheriæ*, by Prof. E. Wernicke and Prof. H. Schmidt. The work has been brought up to date by the inclusion of modern studies on the Schick test and on toxin-antitoxin mixtures. The description of serum sickness following the inoculation of antidiphtheritic serum is, however, confined to one short paragraph.

Prof. H. A. Gins devotes eight pages to a consideration of the *Bacillus fusiformis*. He recognises three different forms: the fusobacterium of Plant-Vincent, the fusobacterium nucleatum, and the fusobacterium polymorphum. Brief mention only is made of the interesting question of the symbiosis of this group of organisms with the spirochætes, a subject on which a good deal has been written lately in connexion with broncho-pulmonary spirochætosis, pulmonary abscess, and gangrene, but probably this subject receives notice elsewhere in this many volumed work. The rest of this section, containing some 400 pages, is given up to a consideration of the tubercle bacillus in its many aspects. Seven professors (B. Möllers, H. Selter, W. Blumenberg, E. Löwenstein, R. Kraus, W. Zwick, and S. Witte) are responsible for this part of the work, and they have discharged their responsibility with success. The pages are packed with information culled from reliable sources. Searching for observations on questions specially prominent at the present time, we find a useful summary of the so-called filtrable virus form of *B. tuberculosis;* the existence of these Möllers considers still sub judice. De Witt and Long's recent work on the chemistry of tuberculosis seems to have escaped notice in the chapters on the chemistry of the bacillus. In dealing with the different types of tubercle bacillus occurring in man and animals the exceptional figures given for Edinburgh by John Fraser are tabulated separately from those quoted from other authorities. It would be interesting to get confirmation of these results by another research under post-war conditions. L. Cobbett's book, the "Causes of Tuberculosis," which gives so much valuable information on tuberculosis in man and animals is not mentioned; being a war-time publication it has not received in continental countries the publicity it deserves. A. S. Griffith's work on the atypical forms of tubercle bacilli found in lupus is dealt with fairly fully. There is also a long and careful analysis of the work of the Calmette school on the B.C.G. culture of tubercle bacillus and its use as a vaccine. Prof. Kraus comes to the conclusion that when inoculated into animals this strain is capable of producing a benign infection with non-progressive lesions which tend to heal, that the strain is therefore analogous to "virus fixe," and that it is capable of being used as a prophylactic vaccine under adequate control.

Other modern developments in bacteriology are critically and sanely considered in this comprehensive work; the broad historical basis on which it is compiled and the successful efforts made to keep it up to date maintain its title to a proud position among works of reference.

The Newer Knowledge of Bacteriology and Immunology. Edited by Edwin O. Jordan and I. S. Falk. London: Cambridge University Press; Chicago: University of Chicago Press. 1928. Pp. 1196. 50s.

Adequate praise may appear exaggerated here. There are over a thousand pages and 82 contributors, and the general standard of the articles is high. Each forms a summary of contemporary knowledge, with a very full list of references. Certainly no bacteriologist can afford to overlook this work, which is sure to save him a great deal of labour in analysing the literature of many outstanding problems. Many of these papers present synopses of matters too new to have become the subject of monographs. Such are the articles on toxins and the estimation of their strength, on the use of human serum from convalescent patients in prophylaxis and treatment, and the isolation of substances with immune properties. The articles on the spirochætes and the bacteriophage are also memorable, and several papers are included on the bacteriology of dairy-farming. We regret that workers other than American are insufficiently represented—through no fault of the editors we are assured.

St. John Ambulance Brigade.—In the report for 1928, which has just been issued, Major-General Sir Percival Wilkinson, the Chief Commissioner of the Brigade, states that 317,671 cases of accident and sudden illness were dealt with, in addition to many thousands of unrecorded cases. During the year there was an increase of 104 divisions, with a personnel of 3662. The strength of the Brigade is now 1684 divisions and 51,631 persons, of whom 13,409 are women; there are, in addition, 202 cadet divisions. There was a large increase in the calls upon the service, and the 106 ambulances traversed more than 271,000 miles. Sir Percival Wilkinson adds: "The desire to join our ranks is reaching all grades of society, all ages, and all professions."

THE LANCET.

LONDON: SATURDAY, AUGUST 24, 1929.

DERMATOLOGY AND GENERAL MEDICINE.

Views upon the functions of the skin and their importance in general medicine have changed a good deal of late years. From being regarded as a protective covering having little relation to vital internal processes, we have come to appreciate the close and intimate associations of the skin with biological activities hitherto held to be but little connected with it. In many ways we have reverted to the opinions of the old-time physicians who laid great stress upon the normal functioning of the skin, and we have been able to elucidate some of the mechanisms by which the benefits of this functioning may be brought about. Thus we have come to realise, for example, the remarkable interdependence of cutaneous activity with that of the vegetative nervous system, and to learn that the powerful influence of season and climate upon health and well-being acquires some explanation through this association. In the Lettsomian lectures, whose publication commences in this issue, Dr. H. W. Barber discusses aspects of this important question which have already received attention. It has been shown by Cramer and others that an influential governor of the activity of the thyroid-adrenal apparatus is found in the heat-regulating function of the skin; moreover, the effective stimulus to this system is change of temperature rather than the exact level at which the temperature is set; variations in climate and rate of movement of air effect more than constancy of heat or cold or the degree of moisture present. Of all climatic factors influencing the human organism the rate of air movement and the intensity of the solar radiation are perhaps the most important. The former, by leading to increased cooling of the body, provokes an increased activity of the thyroid and adrenal, and produces a more rapid oxidation and higher gaseous exchange. Light clothes and a non-stagnant atmosphere are thus important adjuncts to treatment, a point which Jakowenko [1] has lately emphasised in a study of the stimulating effect of sun and air baths at health resorts upon metabolism. It is possible, as recent work has shown,[2] that cooling itself may lead to the formation of a histamine-like substance in the skin—such as Sir Thomas Lewis has shown to be formed after vessel injury—upon which the general effects of cold are mainly dependent. The liberation of an "H-substance"—according to Lewis's brilliant researches—is in the nature of a defence mechanism, being a normal response of the skin tissues upon which reactive hyperæmia, inflammatory changes, anaphylaxis, and similar processes largely hang. Prof. Fröhlich's work, too, has shown the importance of seasonal variations upon the permeability of vessel walls, and the condition known as chilblains is probably an abnormal response of some such defensive process to undue chilling.

The action of sunlight, and especially of the ultra-violet rays of sunlight, is as yet far from fully explained. Their effect is mainly upon the skin, for they do not act deeply, and the problem is intimately bound up with that of epidermal pigmentation. That they lead to a formation of vitamin D in the skin layers is probable, and that their effect is in some way connected with the sympathetic nervous system and the adrenal bodies is undoubted. A chemical hormone is suggested as the medium by which such connexion is effected, and extracts of pigmented skin are said to be both pressor and mydriatic, which points to adrenalin or some similar substance being concerned. Irradiation of the skin, however, while causing increased pigmentation, tends to lower sympathetic tone, though in therapeutic doses ultra-violet light has little effect upon blood pressure, pulse-rate, or basal metabolic rate (Fries and Topper).[3] There are, moreover, important constitutional factors also involved, a point in the study of skin diseases which Dr. Barber emphasises opportunely. In no branch of medicine are constitutional variations in individuals more clearly illustrated than in the investigation of skin responses to irritants or infections. The blonde subject with soft pale skin who blisters readily on exposure to sunlight has long been known to be less resistant to tuberculosis than the brunette who pigments readily in the sun and in whom tuberculosis, if contracted at all, tends to run a more benign course. An immense number of skin tests have been devised with the object of determining such constitutional variations in skin responses, and to such variations much of the incidence of skin diseases is due. Dr. Barber exemplifies such factors by the case of three common external infecting agents of the skin, the pityrosporon, the acne bacillus, and the staphylococcus. He has done great service in pointing out afresh the importance of the seborrhœic "diathesis," or as he has termed it, the "status seborrhœicus," and has drawn a striking picture of the two types of this "diathesis," worthy of the study of all physicians. He holds with others that its essential change is an alteration in the secretion and composition of the cutaneous fat.

Such a conception must clearly have significant and practical bearing upon treatment, and we must look further than the purely local lesions in such conditions as are under discussion. Thus changes in the endocrine glands (particularly, as Sabouraud insists, in the sex glands), in the digestive organs, and in the excretory organs should be looked for in the examination of such cases. The possibility of intestinal toxæmia as a factor is also suggested by Dr. Barber, and in this connexion it is interesting to recall that Lloyd Arnold [4] has lately shown that the bacterial flora of the small intestine may be altered by both diet and climatic changes. Clearly both can be of the utmost importance in the treatment of skin disease. The former by perhaps affecting the nature of the cutaneous fat not only through changes in its quantity but also in its quality, the latter by its influence upon the endocrine glands and the vegetative nervous system. The relationship of fat metabolism to intestinal auto-intoxication and to cutaneous manifestations is one which, as Dr. Barber suggests, may well repay more complete biochemical investigation. The rare conditions of acanthosis nigricans, which occurs in association with malignant disease of the peritoneum and bowel, and of xanthoma, which is invariably associated with greatly increased cholesterol content in the blood, are of interest in this connexion. It is not only, however, with regard to the sebaceous glands that we should pay attention to dirt, climate, and "diathesis." The same wide view of skin disorders must be taken in other conditions besides those of the "seborrhœic state." Eczema and urticaria are, of course, two notable examples in which general principles can never be subordinated to local measures; hyperhidrosis, pruritus, alopecia areata, von Recklinghausen's disease, to mention but a few, show also the importance of nervous factors in ætiology. It is, in fact, not only in ætiology but also in diagnosis and treatment that close study of the skin may reward the general physician, and ever more must a close study of the body as a whole repay the dermatologist.

◆

THE SIGNIFICANCE OF CAROTIN.

Carotin and closely associated lipochrome pigments are widely distributed throughout the world of living organisms, but nothing has been definitely known of any physiological function which they perform in either plants or animals. It seems impossible that they are of no advantage to the plant body, where they are made, but their presence in animals might, of course, be due to their passive ingestion in food.

The frequent association of carotin with substances rich in vitamin A was early noticed and was followed up by J. C. Drummond and by H. Steenbock, and with various collaborators. Steenbock found the association in plant tissues to be very close. Yellow maize, for instance, was well supplied with vitamin A, whereas white maize was not; whilst in the varieties with intermediate shades of colouring the vitamin A value was found to be proportional to the depth of yellowness. In the case of animal fats, however, the parallelism is less exact, and it appears to break down altogether where the liver oils are concerned, although these oils also contain unidentified lipochromes. Carotin itself was actually fed to rats as a source of vitamin A by Drummond (1919, 1920, 1925), by M. Stephenson (1920), and by Steenbock (1921). The two former got negative results, but Steenbock, using recrystallised carotin of constant melting-point, found that it promoted growth in rats on a deficient diet. All these observations, however, except that of Drummond in 1925, were carried out at a time when the fat-soluble vitamins A and D were not differentiated and all tests of substances for vitamin A which were performed in that period are now regarded as unreliable. Drummond's observation of 1925 is not open to this criticism, and has stood in the literature as the chief evidence that vitamin A cannot be supplied in the diet as carotin. This year he has repeated his experiments,[1] and again obtained a negative result, using a highly purified carotin of melting-point 184·9° C. Three other sets of workers, however, report results different from his, but corresponding with one another's. Euler, Karrer and co-workers, Thomas Moore, and Smedley-MacLean, Hume and co-workers, have all found that vitamin A is adequately supplied to a rat on a deficient diet by a daily dose of 0·01–0·005 mg. of recrystallised carotin. The last-named group found even 0·003 mg. to be a sufficient dose of a carotin of melting-point 178° C. and of iodine value 330, and also that the minimal dose decreased with the increasing purity of the preparation. It is true that the melting-point of some of the carotin used by Drummond was higher than that of any used by the other workers, and the truth may simply be that he is working with the pure substance, whilst the others are employing a contaminated carotin in which the contamination represents vitamin A. The situation would then be very like what happened in the case of ergosterol, the parent substance of vitamin D, which proved to be a contamination of cholesterol. On the other hand, something very much more fundamental may be at stake, and it may be that when the cause of the discrepancy between Drummond's result and those of the other workers is explained, our understanding of the chemical nature of vitamin A may be much advanced; though even if pure carotin is found in certain circumstances to supply vitamin A, some additional explanation is needed to include the means by which the vitamin is supplied in liver oils. A contribution by Mr. Moore on p. 380 of our present issue probably brings this explanation a step nearer. In the circumstances of his experiment, the consumption of carotin in large excess by two albino rats did not lead to any considerable increase of pigment in the liver, but was followed by great intensification of the antimony trichloride colour reaction for vitamin A, also in the liver. The observation suggests rather forcibly that the large consumption of carotin had in some way contributed to the formation of a reserve of vitamin A. A further observation of great interest is recorded by Euler and Karrer, but awaits confirmation. They have tested several other lipochrome pigments and their derivatives as sources of vitamin A; most of these were negative, but one, dihydro-α-crocetin, is reported to be active for rats in a daily dose of 0·015 mg.

The problem from the point of view of the colour test for vitamin A was discussed in our columns on August 3rd by Mr. Moore, who pointed out how the intrusion of carotin concentrates, rich in vitamin A, has vitiated the reliability of the antimony trichloride colour test for vitamin A; for such preparations of vitamin A of plant origin a biological test with rats is the only criterion, but the colour test is still held to be valid in the case of liver oils. Should it prove that carotin can in certain circumstances supply vitamin A, another series of researches, which hitherto have somewhat baffled interpretation, would receive an explanation. F. P. Underhill and co-workers,[2] and J. Goldberger and co-workers,[3] last year both described a condition called "black-tongue" in dogs, which is produced on certain diets. Goldberger's syndrome is cured with yeast and seems to represent pellagra in the dog. Underhill's syndrome is not cured with yeast, but with butter, pig's liver, eggs, carrot, and recrystallised carotin. The condition is said not to have been cured with cod-liver oil, and on this ground, and because it is curable with pure carotin, the possibility that it is due wholly or partially to a vitamin A deficiency is dismissed. The diet used appears incomplete in other ways, but on the whole, in view of the list of curative substances, and in the light of the new evidence about carotin, the suggestion that this form of black-tongue is due to vitamin A deficiency certainly deserves reconsideration.

CARDIO-AORTIC SYPHILIS.

BOTH the difficulty in diagnosis and the disappointing results of antisyphilitic treatment in cardio-aortic syphilis were referred to by those who took part in the discussion on this subject at the meeting of the British Medical Association, a report of which appeared on p. 330 of our last issue. There is a general consensus of opinion that the common cardiovascular syphilitic lesion is an aortitis. This often gives rise to no symptoms whatsoever, and is only discovered post mortem in a patient who has died of some other disease. Sometimes, however, the aortitis leads to aneurysm of the aorta—perhaps the most distinctive of the syphilitic lesions, since it is so rarely due to other causes. Sometimes the process involves the root of the aorta producing incompetence of the aortic valves, or leading to partial obstruction of the orifices of the coronary arteries with its sequel angina. Aortic incompetence is, however, also a common result of rheumatic infection, though it is then generally associated with mitral stenosis. Similarly coronary arterial disease may be a part of the general degenerative process accompanying senescence, and the resulting ischæmic fibrosis is of a similar nature to that produced by syphilis. Age, therefore, is an important consideration in the diagnosis. Rheumatic heart disease is essentially an affection of youth, while atheromatous changes appear late in life. Syphilitic heart lesions, on the other hand, generally become manifest between the ages of 35 and 50, and the sudden appearance of anginal symptoms or the discovery of aortic regurgitation, in a previously healthy subject, in middle life, should at once arouse suspicions of a possible syphilitic ætiology. The Wassermann reaction is less helpful in diagnosis than the casual observer might anticipate. As several speakers pointed out, symptoms of heart disease plus a positive Wassermann are by no means conclusive of cardio-aortic syphilis, and still less does a negative Wassermann exonerate syphilis as the causal factor. The symptoms of cardiovascular involvement do not generally make their appearance for 15 years or more after the primary infection. But, once they have appeared, the progress of the disease is often rapid, and it is unusual for the patient to live for more than two or three years after the condition is first diagnosed. By thorough antisyphilitic treatment of the primary infection we may hope to prevent the development of cardiovascular lesions; but when once those lesions can be recognised, neither arsenic, mercury, nor iodides will give more than a temporary relief. The treatment then becomes that of heart failure, and antisyphilitic remedies are a secondary consideration.

It is possible that the future may have in store new developments in the clinical outlook on cardiac syphilis. WARTHIN has been able to demonstrate the presence of spirochætes in the heart muscle of a series of patients who died suddenly after a brief period of ill-health—generally less than 48 hours. These cases he regards as examples of malignant exacerbation of latent syphilis. He has also demonstrated certain more chronic lesions of the heart muscle which he believes to be pathognomonic of syphilis, and is of the opinion that syphilitic myocarditis is a much more common condition than is generally believed. At the present time there is no link between these pathological findings and the clinical manifestations, but the evidence is sufficiently definite to suggest that it may become necessary to modify our present view of cardiovascular syphilis as being essentially an aortitis.

RAY LANKESTER.

SIR EDWIN RAY LANKESTER, whose death at an advanced age occurred last week, was the most widely known man of science in England, and among not only his acquaintances but his intimate friends he could count a large number of medical men of every sort of different standing or specialty in the profession. By family ties this was made probable, for he was the eldest son of Dr. EDWIN LANKESTER who succeeded the founder of THE LANCET as medical coroner for Central Middlesex, while his brother is a well-known physician, and his own training, after a boy's acquaintance with classics, was purely on scientific lines. Thus it was natural that LANKESTER should appreciate, instinctively or logically, the aims of medicine, and medicine owes him a debt in many directions. He was the leading zoologist in this country, and we do not know who has a better claim than LANKESTER to be considered the leading zoologist of the world. Not only was his equipment perfect but he had a genius for communicating his knowledge. As lecturer and author alike, his clear arrangement of material and his logical methods of expression introduced to a varied public those scientific aspects of biology which were exactly needed for a comprehension of the large outlook of medicine; and his immediate pupils, who benefited alike by his genius and his friendship, became themselves agents for spreading still further the doctrines of progressive biology. Through them, as through his own great personality, LANKESTER can be considered a pioneer along many different lines of medical thought and work—lines which would never have been laid down had it not been for the constructive genius and power of logical coördination which suggested them.

Annotations.

"Ne quid nimis."

INFANT MORTALITY.

AT the end of the week there was issued from the Ministry of Health a Report on Infant Mortality,[1] constituting the English contribution to an international inquiry which has been instituted by the League of Nations. In accordance with a general plan the English inquiry takes the shape of an investigation in certain parts of Staffordshire and in Sunderland where infant mortality is relatively high, and in Oxfordshire and Croydon where it is relatively low. The primary object of the inquiry was to ascertain the causes of infant mortality in these centres during 1927 and 1928, and previous investigators of the subject will have the satisfaction of knowing that the general findings of the inquiry support views which are already held, little having been elicited that was at variance with English experience.

Throughout the Report the subjects of infant mortality in these districts are considered under two heads—namely, (1) stillbirths and deaths during the first six months of life (neonatal deaths), and (2) deaths from postnatal causes—and the main part of the Report is taken up by an analysis of the principal causes of these two groups of deaths in the four selected localities. The analysis is accompanied by statistical notes from Dr. Peter McKinlay upon such points as *mortality in relation to the order of birth* in the family, the birth-rate in relation to the social status and housing conditions of the family, and the mortality in relation to those conditions, and in relation to the age of the mother, and the well-being or indigence of the family. The general findings of the Report are confirmatory of previous experience in respect of all the circumstances adduced. Thus first pregnancies are found to be attended with a higher death-rate than is met with in the immediately subsequent group of births, but the latest children born have, on the whole, the highest mortality-rate. Clinical experience would have anticipated this, as it would also have anticipated the conclusion that bad housing and overcrowding are definitely prejudicial to infant life, although neonatal cases are much less closely associated with a dense population than are the deaths from postnatal causes. There is a fairly clear dividing line between the causes of stillbirths and neonatal deaths on the one hand and deaths after the first month of life on the other. Out of 1083 deaths investigated in the selected districts, 774 were either born dead or died during the first month of life, prematurity and obstetric difficulties, including ante-partum hæmorrhage, accounting for the figures; while in the second group of older infants we find respiratory diseases and gastro-intestinal diseases, many of which have an infective origin, to constitute the main scourges of infancy.

[1] International Inquiry, Health Organisation of the League of Nations (English Section). Report by Dame Janet Campbell, M.D. With Statistical Notes by P. L. McKinlay, M.D.

The manner in which the investigation has been conducted makes the Report a valuable document for reference; new facts or new doctrines it may not contain, but it forms a good example for local investigation with regard to a subject which every health authority of the country must keep prominently before their own and public attention. The first concrete suggestions of the Report are that general sanitary environment, and particularly housing, requires improvement, and that there should be established throughout the country a maternity service for mothers whose circumstances call for such aid, the service to include adequate attendance at childbirth and hospital provision for abnormal cases, or where domestic environment calls for it. Other suggestions are, and naturally are, that home-visiting and welfare centres should be developed, that a domicilary nursing service should be instituted, and that domiciliary medical attendance under the National Health Insurance service should be extended and hospital accommodation for infants increased. At the close of the document appear the following far-reaching and valuable pieces of advice—namely, that further scientific investigation of infant hygiene should be conducted together with training of medical students in the subject, and that the public generally should be educated in the importance of securing suitable provision for maternal and child welfare. Dame Janet Campbell's words which close the Report allow that little elucidated or suggested in it will be new to students of this question, but describe the paramount value of the investigation as lying in the more exact definition and emphasis of certain known but not always fully recognised facts and in the clearer light which it throws upon conditions under which many babies now live and die. She would have us not rest content with thinking that the present machinery for supervising infant health and welfare is relatively complete and satisfactory, for "much yet remains to be done before it can be said with truth that the pregnant woman and the young infant are receiving all the support and all the assistance due to them from the community if the children of the nation are to multiply and prosper." Every social worker will be in agreement here.

NERVES IN CANCERS.

THE most fundamental character of tumours is their functional isolation from the harmonious corporation of the body in which they live; they live for themselves alone. Correlated with this isolation is the traditional fact that they have no blood-vessels or nerves of their own; we call it a "fact" because there is still no reason to doubt that in a broad general way it is true. The more we know of tumours, however, the more we realise that they grade into normal tissues, structurally and functionally, and some of them reproduce something of the physiological action as well as the histological structure of the organs from which they spring. We might therefore expect that in some instances tumours might be found to have some blood-supply and some nerves of their own, not to the normal extent but imitating it in greater or less degree. That secondary tumours may excite a new growth of vessels out of proportion to the connective tissue reaction has been known for some time. A few observers have claimed that they may do the same with nerves, and Prof. H. Oertel, of Montreal, has lately published [1] the results of a long search in human tumours by the new silver methods. He shows beyond much doubt that nerves can be found in a good many new growths, and from their intimate disposition in relation to the neoplastic cells he seems to have made out a fair case for his belief that they are in functional relationship to the tumour tissue, supplying the parenchyma as well as the vessels and connective tissue. By the nature of the case anatomical evidence by itself can hardly be quite convincing, but his descriptions and illustrations merit careful study. Negative findings are of little importance; knowing the lawlessness of tumours in general we should hardly expect that all of them would have nerves, and that most have no nerves is no great argument against the thesis that some possess them.

PNEUMOCONIOSIS.

THE list of pneumoconioses, as every student knows, begins with anthracosis, a term applied to a pulmonary fibrosis affecting the workers in coal mines and, more loosely, to the pigmentation of the lungs of town dwellers as commonly revealed at autopsies. The researches of André Jousset[2] who has made a careful pathological and chemical study of the pigment found in the lungs of both town dwellers and coal miners, indicate that the use of the word anthracosis in either connexion is incorrect. He maintains that what has been assumed to be carbon is in reality a residue of black oxide of iron, "not physiological dirt but pathological dross." The black oxide may be the legacy of hæmolysis following stasis, in which case yellow pigment is produced, or of infection and inflammation which whether acute or chronic results in a deposit of black pigment. The mixture of the two pigments commonly found points to their community of origin. The large detached alveolar cells, often described as "dust cells," according to Dr. Jousset do not contain infected particles of inhaled carbon or other foreign matter, but pigments representing different degrees of oxidation of iron derived from hæmoglobin. When tuberculosis has been found in the "anthracotic" lung, it has been assumed that the tubercle bacillus has found a suitable nidus in tissues which have undergone fibrosis due to the irritation of inhaled carbon. But carbon is not a pulmonary irritant and the examination of the sputa of miners made at intervals after they have left the mine shows how rapidly the lungs clear themselves of coal dust. The source of the pulmonary pigment must be found elsewhere. Dr. Jousset points out that pulmonary tuberculosis is always accompanied by a deposit of melanin which impregnates even the smallest tubercles and is especially well seen in the environment of cavities. Thus the pigment, in these cases as in other congestive and hæmorrhagic states of the lung, is the result and not the precursor of disease. The French miner, as such, is neither more nor less liable to consumption than other workers. But mining is not simply a matter of digging for coal, operations in many of the French coal mines include rock-drilling, and in work of this type inhalation of siliceous dust is possible. It has been found that workers at the rock-face are specially liable to pulmonary complaints. An analysis of the lungs of miners who had died as the result of accident showed a comparatively high percentage of silica and iron. Silicosis, sclerosis, and pigmentation would thus seem to be three stages in the development of "miners' lung."

[1] Jour. of Path. and Bact., 1929, xxxii., 557.

[2] Rapports de l'anthracose et de la tuberculose pulmonaire, Rev. de la Tuberculose, 3e Série, 1928, ix., 884.

If too much attention has been paid to anthracosis as a possible source of disease, too little has been paid to other occupational causes of pulmonary fibrosis. Attention has recently been directed to the grave results which may follow the inhalation of asbestos dust in factories for the carding and spinning of this substance.[3] Asbestos fibre contains a relatively high percentage of silica and this differs from carbon in having an intensely irritant action upon the mucous membrane of the bronchial tree. Pulmonary asbestosis, when once established gives rise to an intense dyspnœa which precludes the patient from the slightest exertion, may be accompanied by extreme cachexia and often leads to an early death from broncho-pneumonia. If the student must omit anthracosis from the head of his list of pneumoconioses asbestosis should be substituted for it, at any rate, till more vigorous action on the part of those charged with the supervision of factories and the control of occupational diseases has reduced the incidence of this disease.

EXPERIMENTAL ELECTRIC SHOCK.

A COUPLE of years ago we commented[4] on a paper in which Dr. R. W. Ian Urquhart, of the University of Toronto, described experiments on the effect of strong alternating currents on the nervous system of animals. He showed then that when an alternating current of suitable strength was passed through the base of the brain, the nerve centres were paralysed or blocked in such a way that the respiratory, vagal, and conjunctival reflexes were inhibited. Provided that there was no charring, these reflexes returned after a time if efficient artificial respiration was kept up. In collaboration with Dr. E. Clark Noble, Dr. Urquhart now records[5] further observations on this condition, which he terms a-c block, to distinguish it from the anelectrotonus produced by a direct current. Shocks were administered to the cardinal centres of the brain and spinal cord and to the sciatic nerve of rabbits. In the experiments on the brain, one of the vagus nerves was isolated and severed at the level of the cricoid cartilage and arranged so that the central end could be stimulated by weak induction shocks. The occipito-atloid membrane was exposed, and a special button electrode applied to it. A point electrode was inserted high up the nose. The current, which was applied as soon as the animal was enough recovered from the anæsthetic to give a conjunctival reflex, varied from 1200 to 1850 milliampères, and was passed for two seconds. Artificial respiration was begun as soon as possible after the current was broken, and it was found that normal respiration returned at varying intervals up to three and a half minutes, the pupillary reflex and vagal response reappearing decidedly later, always within a few seconds of each other. The relative shortness of the block was presumably due to the immediate commencement of artificial respiration. Further tests of no little clinical importance showed that if resuscitation was delayed for two and a half to three minutes, the animal rarely recovered; that no advantage was gained by the use of pure oxygen or of oxygen and carbon dioxide mixtures, and that the chance of recovery was not increased by injections of adrenalin. Currents of varying frequency all produced much the same results. Tests were also made on ten rabbits to determine the truth or error of the current belief that shock patients sometimes relapse after spontaneous breathing has been re-established. Two of the animals were found dead next morning, but the other eight were apparently quite unharmed. Since the cause of death could not be ascertained, the authors regard the experiment as inconclusive. The attempts to demonstrate block in the spinal cord met with many technical difficulties, but it was established that a current of 750 ma., applied for two seconds, produced a block lasting five minutes in a decerebrate cat. In the sciatic nerve of the rabbit the smallest current that would produce block was 2 ma., applied for two seconds. The block was confined to the length of nerve through which current was passed, and did not spread as in anelectrotonus. Its duration varied directly with the strength of the current, and after a certain limit recovery did not occur.

These experiments bear out still further the importance of starting artificial respiration immediately after an electric shock. They show that whereas it is possible to save life and health by immediate first-aid, a delay even of a couple of minutes may mean the loss of the patient. This fact should be impressed on the minds of all electrical workers.

THE ANXIOUS LITTLE TACHYPHAGE.

New York is said to possess an organisation known as the Three-hours-for-lunch Club, which was devised to combat the evil influence of the quick-lunch counter. The "anxious little tachyphage," a type of dyspeptic admirably described by Dr. Paul Michon,[1] would certainly not be eligible for membership until he had radically revised his habits. Live with him for a day, says Dr. Michon, and his digestive troubles will be more easily understood. He wakes in the morning with a tight feeling in his epigastrium at the thought of what is before him, lies in bed too long thinking about his troubles, hurriedly gets through his dressing, toys with his dull breakfast, and rushes off to the office. At every delay on the journey the epigastric discomfort reminds him of its presence, and a morning spent in telephoning, interviewing, and correspondence harasses him still further. Home to lunch with the telephone too close to his table, he bolts his food, drains his glass at one gulp, and throughout the meal crumbles bread and chews at it nervously. Then to the office again, he throws himself once more into the press of business, and ends the working day with a hurried dinner so as to rush off to a theatre or reception. This sort of thing continues year after year, its victim constantly denying the possibility of anything going wrong with his health, until quite suddenly the suggestion of an ulcer or growth in his stomach brings the "tachyphage," a little more anxious than usual, to the physician. Unless he is lucky enough to meet someone who really understands the sort of life he leads he may quite well be sent away with merely an alkaline powder and some pious hopes about his diet. Dr. Michon insists on the essentially psychopathic nature of the malady and prescribes his treatment under three headings. First, there is the direct treatment of the stomach, and this is to be reduced to a minimum. Alkalis are definitely forbidden, and all that is allowed is a powder of animal charcoal or of kaolin before the main meal of the day. Secondly, there is the treatment of the "tachyphagia"; instructions for this must be written. Regular hours for meals and a generous allowance of time for each meal are important, while papers, messages, and the telephone must be banished during its progress. At the meal itself solids must be chewed and not bolted, and liquids taken in small portions throughout, while a definite and reasonable ration of bread should be selected beforehand and not exceeded. Thirdly, the general anxious state must be dealt with by what some people may call psychotherapy and others common sense. Walking without hurry should be substituted as far as possible for other modes of transport, while moderation in all work and the various forms of pleasure-seeking must be tactfully counselled. Medicaments to curb the activities of the sympathetic nervous system, such as belladonna, may be administered before meals, and especial attention should be directed to securing regular hours of sleep, for which purpose sedatives such as valerian and the bromides are recommended. This is all very well, a critic may say, but how is one to tell that this sort of treatment is all that is required, and how many times will a real case of gastric ulcer or of malignant disease give much the same sort of vague story as this other type of case? Dr. Michon does not despise radiological assistance, but he thinks the diagnosis pretty evident from the patient's appearance and behaviour. Look at this man, he says, still young, who comes to consult you for gastric trouble. His rapidly roaming eye looks first at one corner of your consulting room, then at another, now stares you straight in the face, now is off on another tour of inspection. His restless face looks as if the worst is about to happen, and in a brief and nervous way he describes his symptoms, none of which really suggest the idea of an organic lesion. Such, he holds, and with good reason, is the clinical picture of the "anxious little tachyphage"—a figure who is becoming increasingly common in these islands. Possibly the best way to combat this occupational disease would be to invite the Three-hours-for-lunch Club to start a mission in England.

HEALTH AT THE JAMBOREE.

THE organisation of the Boy Scouts' World Jamboree at Arrowe Park, Birkenhead, nowhere showed to better advantage than in the medical department. The hospital, which was in charge of the Medical Commissioner, Lieut.-Colonel J. C. Holdich Leicester, consisted of nine marquees and six bell tents. Four of the marquees were wards, each holding 16 beds. Another was divided into two parts, one-third of its space being used as a dispensary and the rest as an emergency operating theatre. A sixth marquee, similarly divided, served as a dental clinic and an out-patient department. The remaining three were used respectively as an office, a store, and a dining-tent for the staff. One of the bell tents was a store-room for patients' clothing and the other five were isolation wards. A small portable plant supplied the hospital with electric light, and all the units were linked by telephone. Cooking was all done out-of-doors under a corrugated iron roof. The Cheshire Girl Guides Association supplied the entire nursing and executive staff, whilst Colonel Leicester was assisted in his medical work by three local practitioners and a number of local honorary consultants. The dental clinic was under the supervision of Mr. H. H. Tomlinson, who was assisted by a staff of six dentists.

More than 30,000 scouts attended the camp, and it is surprising that in the three weeks only 321 had to be admitted to hospital. Of these, 52 were evacuated to local hospitals as being likely to need attention for more than a few days; this figure included nine cases of infectious disease sent to Birkenhead Fever Hospital. All the rest returned to their units relieved or cured. Tonsillitis accounted for 70 cases, and the next commonest types of ailment for which admission was necessary were cuts, stings, or bruises (39 cases). These were closely followed by chills, malaria, and malaise (28 cases), and pyrexia (26 cases). There were 21 fractures and dislocations, 14 sprains, 15 cases of constipation and colic, and 14 of other stomach troubles. Considering the mud and damp in which the camp has lived, the proportion of respiratory disorders was low; there were 11 cases of asthma, bronchitis, and catarrh, 8 of "influenza," and 7 of pneumonia and pleurisy. Coughs and colds might have been expected to number more than 80, while rheumatism accounted for only 3 admissions. Twenty operations were performed for the reduction of fractures and repair of other injuries. The out-patients' department was attended by 1229 boys, 271 of whom had cuts and wounds (68 septic), and 125 had boils. Scalds, burns, sunburns, and abrasions accounted for 108 more. Naturally the greatest number of in-patients were English: 160. French followed with 47, and Scottish 12, Welsh 12, Irish 11, and American 9, came next. A really remarkable absence of epidemic disease and of serious illness in such a large concourse was very largely due to the efficient hygienic precautions taken by the Assistant Camp Chief (Health), Major M. B. Ritchie, ably seconded by the Hygiene Commissioner, Dr. Richard Wyse. The stagnant pools in the woodland areas were freed from infestation and the water-supply was carefully planned. The latrines were adequate in number and suitably placed, and an expert staff saw to their emptying and cleansing. The camp was patrolled by members of the St. John Ambulance Brigade and the British Red Cross Society, and whenever possible the boys were medically examined before coming to camp. There is a first-aid post under medical supervision at the rest camp organised at Earl's Court for scouts who wish to stay in London before or after the Jamboree. Here, again, local hospitals are coöperating cordially. The organisers and medical staff are to be congratulated on the success of their work, which may well form a model for future encampments of the same kind.

THE TREATMENT OF ENURESIS IN CHILDREN.

THE psychological causation of nocturnal enuresis in children is much emphasised nowadays, and many writers discredit all forms of treatment by medicaments, diet, restriction of fluid, or the various forms of surgical intervention. Two recent papers illustrate possible methods of approach along the lines of what is called psychiatry. Dr. R. C. Hamill[1] holds the view that enuresis is a conduct disorder and can be perfectly well stopped when the child so desires. He explains to both child and mother that the only reason why the bed is wet is that the child prefers a wet bed to getting up, and once the child admits this and assumes responsibility for its conduct a cure is effected. In Dr. Hamill's opinion any other suggestion will only be detrimental to the child's interests; to accuse the tonsils, prepuce, hereditary influences, and so on will merely furnish the child with excuses for its ill-behaviour. With a young child the mother must quietly assume that nothing short of a dry bed every night can possibly be expected from her offspring, and with an older one, who can understand Dr. Hamill's ingenious explanation of conscious control during sleep, a few talks at the psychiatric clinic will usually complete the cure. Out of 80 cases thus treated 40 were entirely rid of the habit, and of the other 40 some were improved, some not improved but still under treatment, and some had been lost sight of. Dr. Hamill claims that this treatment is "specific," and Dr. I. S. Wile makes a similar confident claim of great success for two methods of treating enuresis which he brings forward.[2] Dr. Wile says that for cases of enuresis in institutions the method of personal approach to each child is quite impossible, so in the first of his two methods a "group approach" was employed. In this scheme the inmates of the institution—the Hebrew Orphan Asylum in New York City—were divided into teams, and the object of the campaign was explained separately to the boys and girls. Each team elected a captain, and each week the percentage of dryness was calculated for the various teams so as to foster the competition spirit. The method employed by the teams was left to their discretion, but the usual plan was to wake up the offending members or to encourage the weaker members to greater efforts by means which are not stated but can be imagined. When a member of one of these enuretic teams had remained dry for four weeks he or she was allowed to enter a regular dormitory. This scheme worked very well over a year, and for the second year the boys and girls were allowed to carry on without the interference of the "psycho-pediatrician" with equally satisfactory results. The second plan which Dr. Wile employed was to wake all male enuretics at 9 P.M., 12 midnight, 2 A.M., and 5 A.M., *the child being made to get up* and visit the closet. The percentage of cures in this group was somewhere in the neighbourhood of 30 to 40 per cent., while by the "team" method the results seemed slightly lower, although their assessment was more difficult. Dr. Hamill claims for his plan of putting the responsibility on the child that it greatly aids in the development of character, by encouraging the inhibition of impulses without conscious effort, while Dr. Wile says that the cured children in his series "reflect their new power in personality and in physical health, together with some intangible immeasurable advantages along the line of better emotional stability, greater intellectual application, and finer social balance." Such claims have never been made for the old-fashioned belladonna method, but the percentage of cures obtained was probably very much about the same.

THE IMMUNISING DOSE OF VACCINIA.

THE Rolleston Committee on Vaccination, in their report to the Ministry of Health last year, pointed out that definite experiments do not seem to have been made "to determine the minimal dose sufficient to give rise constantly in the human being to the characteristic vesicular manifestation and to immunity lasting for a reasonable time." In the light of their suggestion that "experimental observations be made to ascertain if it is feasible to increase the dilution of vaccine lymph beyond the present degree without impairing its efficiency," it is interesting to note some results obtained by Dr. Peter Clearkin,[1] of Tanganyika, in an investigation of vaccinal immunity in monkeys. He used a variolous strain obtained from a case of small-pox in 1920. Its virulence was maintained by alternate passage from calf to animal, and the titre was ascertained by the intradermal injection of 0·1 c.cm. of serial dilutions on the shaved abdomen of the monkey. The highest dilution causing vesiculation was taken as the titre, and the minimal infective dose was calculated from it. The immunity of the monkeys was tested, from 14 to 28 days later, by insertions of serial dilutions of a fresh, very active vaccine. The number of monkeys used was not large and the estimation of the minimal infective dose in this way is rough, but the experiments showed that very small quantities of vaccinia virus protect against enormous doses. The immunity given by 60 minimal doses was as strong as that given by 20,000, and protected against 50,000 minimal infective doses. In another experiment, *two minimal infective doses protected against* 100,000. Dr. Clearkin thinks that these results form a useful guide in the vaccination of human beings, since the dermal reactions of the monkey are very much the same as those of man. He points out, however, that the whole problem *of anti-variolous* immunisation is bound up with the production of a stable vaccinia virus.

OPHTHALMOSCOPIC SIGNS IN HEART DISEASE.

A PAPER by Wallan M. Yater and Henry P. Wagener, of the Mayo Institute[2] analyses the post-mortem findings in 137 cases of heart disease, in which the fundi had been examined ophthalmoscopically during life. The cases were classified first according to species of heart disease and secondly according to character of the changes observed in the fundus. The writers conclude that ophthalmoscopic examination yields negative results in heart disease unless this is due to or associated with hypertension, coronary sclerosis, or subacute bacterial endocarditis. Of the 137 cases, 8 had subacute bacterial endocarditis, death being due to septicæmia in all cases. Embolic lesions were noted in 2 cases. Thirty-two patients were classified under the heading of hypertension; of these, 25 died of cardiac decompensation with or without uræmia, 4 of hemiplegia, 2 after operations, and 1 after an accident. All but one out of the 32 showed sclerosis of the retinal arteries of "hypertension type"; by this the authors mean generalised constriction of the calibre of the arteries with exaggeration of the arterial reflex stripe, irregularities in the lumen of the arteries, and arterio-venous compression. In addition to these changes, 17 showed retinitis—i.e., scattered cotton-wool patches and hæmorrhages and œdema of the retina, occasionally even œdema of the disk. In three other cases there were hæmorrhages not severe enough to come under the term retinitis. In this series, therefore, very nearly all those cases of heart disease which were dependent on high blood pressure alone showed retinal changes. Among 25 cases in which coronary sclerosis was found, 19 deaths had been due to causes purely cardiac and six followed operations. In many of these cases, and also in 11 cases of mixed type, high blood pressure was present and fundus changes had been recorded. These changes were often merely indicative of what the authors term senile arterio-sclerosis—that is, only *an alteration in the light reflex, difficult to diagnose* without any marked constriction of the retinal veins or alterations in the calibre of the arteries. Leaving these mild cases aside, the investigation showed that out of the 137 cases under review 52 had been diagnosed as having retinal arterio-sclerosis of the more severe or unmistakable type with or without retinitis. Even more interesting is the observation, already recorded, that, in the 32 cases in which hypertension was the only cause of cardiac disease discovered, typical retinal changes had been present in 31.

DIABETIC COMA.

Dr. E. P. Joslin[1] *does well to point out that* although seven years have now passed since the discovery of insulin, diabetic coma goes on taking its toll. It is, as he says, high time that deaths from this cause became very rare, and the simple outline of treatment which he sets out would go far towards achieving this if it were generally carried out. The treatment of the emergency of coma should, he says, take precedence over everything else and as soon as the diagnosis has been made insulin should be injected subcutaneously every half hour in doses of from 10–40 units or more until returning consciousness, normal respiration, and decreasing glycosuria show that recovery is beginning. To meet dehydration, a quart of normal saline should be injected subcutaneously at once, because in coma it is dangerous *to trust to retention* and absorption of liquids by the mouth or rectum. Intravenous injections are satisfactory if given slowly to avoid distension of the heart. The circulation, he suggests, may be stimulated by caffeine sodiobenzoate in doses of grs. 7½ given if necessary four-hourly. The stomach should be gently washed out so that liquids will be retained, and fluid containing about 50 g. of carbohydrate should *be given in the first 24 hours.* A gradual return to simpler articles of regular diet may then be made, the dose of insulin being regulated by frequent urinary tests, at first every two hours and later every four or six hours. The dose of insulin should be 15 units for a red reaction with Benedict's solution, 10 for a yellow, and 5 for a green, and no insulin is required if the urine is sugar-free.

Prevention, however, *is better than treatment* and the patient must be taught to avoid coma. He must never omit insulin, in Joslin's opinion, so long as there is sugar in his urine, and irrespective of the diet he is taking he must increase the dose if he has fever or an infection. This is an aspect of the subject lately treated of by Dr. R. Boulin,[2] who places infection in the first rank of causes predisposing to coma. The more impressive conditions such as pneumonia and gangrene are, of course, not likely to be overlooked, but sore-throats, influenza, boils, and small infected ulcers have an importance to the diabetic which is out of all proportion to their apparent gravity. Coma in a chronic diabetic accompanied by any of the above conditions does not react easily to insulin and the prognosis is correspondingly grave. Next to infection emphasis should be laid on fatigue, both physical and mental, whilst shock from trivial injuries, and intoxication by alcohol or anæsthetics are other important precipitants of coma. Error in the diabetic régime is another and better recognised factor, and in this connexion Boulin mentions especially excess of animal proteins. In some diabetics, he says, too much meat is a far greater danger than too much fat. Surgical intervention is an obvious risk; this should not, however, mean that its aid is withheld or even postponed, but only that due precautions are observed. Starvation he regards as a valuable weapon in the treatment of precomatose conditions. The argument that because in the normal subject it produces slight acidosis it is therefore likely to increase the acidosis of diabetes, he dismisses as unjustified by facts; many authorities have consistently used complete starvation to reduce acidosis and have found it quick and reliable. As regards diagnosis he lays stress on the gradual onset of mental and physical feebleness passing progressively into loss of consciousness. Coma never comes on unless there are large amounts of sugar, and acetone as shown by the ferric chloride test, in the urine; but it is impossible by urinary examination alone to estimate the degree of acidosis, for this will depend upon the extent to which the kidneys allow these bodies to pass. Other and well-known signs of coma are loss of appetite, diarrhœa, vomiting, and abdominal pain, whilst the association of slow and ample inspiration and forceful expiration with a smell of acetone in the breath is, of course, conspicuous evidence of its commencement.

THE TRANSFUSION OF IMMUNISED BLOOD.

WE may reasonably look on serotherapy as being still in its infancy. At birth it was the idol of all beholders; then it seemed to lose weight and popularity; and now once more it shows signs of being a credit to the family. Notable advances have been made of late years, for example, in the therapeutic use of convalescent serum in quite a number of diseases, such as poliomyelitis and measles. But obviously there are many difficulties in the way of getting suitable and sufficient serum from convalescent patients and the method has many limitations. The main effort is therefore concentrated on attempts to produce blood or serum with strongly antipathogenic properties. Theoretically, it should be possible to render whole human blood more potent in this respect than any animal serum, but in practice it has not proved very easy to do so. In applying the method to the treatment of acute illnesses most of those working along these lines have of necessity utilised non-specific transfusions, the donor of the blood being actively "immunised" by injection of an indifferent "antigen" such as nucleic acid or a stock vaccine. It is customary to take the blood within 24 hours—usually about six to eight hours after the inoculation—and give it at once to the patient. In less acute conditions there is, of course, time in which to try more specific immunisation of the donor, a procedure which ought to be free from risk if it is done carefully. Thus in treating enteric fever J. Clemens[3] gave injections of typhoid vaccine to the donors until the agglutination-titre of the serum had reached a high value, and carried out transfusion of blood to the patient without any danger or disadvantage to the donor. Greater difficulty is likely to arise with streptococcal infections in which immunisation is attempted by means of autogenous vaccines, and Clemens preferred to use blood taken from people who had recovered from septic wounds or erysipelas, seldom employing any preliminary inoculations to raise their immunity. The choice of donor depended on study of the bacterial flora of secretions from the wound and of organisms obtained from the patients' blood, and in the few cases he describes it appears that proven streptococcal septicæmia which had shown no improvement after frequent injections of streptococcal serum and other treatment were completely cured. It is to be regretted that fuller details of these cases are not recorded, but so far as they go they support the view that immunisation of a donor by autogenous streptococcal vaccines as a preliminary to blood transfusion might be carried out in such a way as to prove useful in such conditions as subacute malignant endocarditis. Some of the work done in this country has indicated that a similar course of treatment may prove of value in conditions of chronic toxæmia such as are sometimes present in rheumatoid arthritis or ulcerative colitis. With highly virulent organisms the process of immunisation is likely to take a considerable time, but in good hands it should certainly not be dangerous. In spite of the practical and theoretical obstacles which begin to crop up as soon as the subject is closely examined there are undoubted possibilities in this line of treatment, and it is not too much to hope that some of them may soon be realised.

SPECIAL GLASS IN SCHOOL WINDOWS.

OPINION still differs about the value of having school-room windows made of glass which is pervious to ultra-violet rays. We know that ordinary glass cuts off most of these rays, including those of shortest wave-length which are said to be peculiarly beneficial to health; we also know that specially prepared glass will let such rays through; further, we may take it as proved that exposure to these short rays is often beneficial to weakly children. Here, then, is evidently a prima facie case for practical experiment, and such an experiment has now been made. In 1925 a test undertaken in a Smethwick school showed striking benefit to the health and nutrition of children who had their lessons in a class-room with windows of vita-glass, which is perhaps the best-known variety of special window glass of the kind under consideration. These results got a good deal of publicity, but it was felt that the small number of children (30) and the lack of adequate controls made their reliability doubtful. Therefore last year, at the instance of the Board of Education, a thorough investigation was made in which a large group of children (240 in all) was kept under more elaborate observation. In his annual report Dr. Paul, the school medical officer for Smethwick, records the method and results of this research. Two classes were selected in each of three different schools, great care being taken to ensure that each pair contained children of the same average age, 5½, 8½, and 10½ respectively, of the same social status, and with similar school curriculum and environment. In each group one class was kept in a room with special windows, and for over a year from May, 1927, careful records were kept of the children's height and weight, and of their hæmoglobin index by von Fleischel's method, whilst educational tests were also systematically conducted. From the tables showing the figures at the beginning and end of the experiment, which are set out in the report, it appears that growth was in no way greater in the vita-glass classes than among the controls, whilst the educational tests had inconclusive results, the most favourable figures being spread fairly evenly over both sets of classes. The average attendances were also no better in the vita-glass classes. On the other hand, the hæmoglobin content figures were consistently better in the vita-glass classes, the average increase for them being nearly 13, whereas in the control classes it was only about 7½. Critics familiar with the technique of von Fleischel's method might suggest that this difference is not significant, but in view of the scientific and judicial way in which the research was carried out, these figures must be taken to mean a real difference in favour of the special glass. On the whole, however, it is impossible to deny that the benefit to the school-children from the vita-glass windows was very slight, the reason probably being that children sitting upright in a class-room with their clothes on have very little of their skin exposed to the light. When, as in special establishments, they can be recumbent and unclothed with the light falling on them from above, the benefit is generally accepted as considerable, and the effect would doubtless also be more marked in places where there is clear air and much sunshine. The daily average of sunshine at Smethwick was only 2 hours 45 minutes, and for two hours (noon to 2 P.M.) of the sunniest part of the day the children were not in school. These factors would more or less hold good for English schools in general, and considering that vita-glass tends to lose its special penetrability with time and is a good deal more expensive than ordinary glass, it scarcely seems sound policy to reglaze all class-rooms. Certainly it would be undesirable to do so if such a step were thought a satisfactory alternative to the establishment of adequate open-air schools where sunlight can act under much more favourable conditions and in company with many other healthful influences.

A NEW VACCINATION ORDER.

THE Minister of Health has adopted the four first recommendations of the Committee appointed by his predecessor in 1926 to consider, inter alia, "the practical methods which are available in the light of modern knowledge to remove any risks which may result from vaccination." An Order issued this week gives effect to the change of policy, and an account of its provisions will be found on p. 411 of our present issue. It instructs public vaccinators to make single insertions of lymph instead of the four which were previously required; multiple insertions will be available for those who wish to gain maximal immunity at one operation. As a corollary to the smaller dosage the rule is altered by which the Ministry did not allow revaccination, by public vaccinators, below the age of 10. Revaccination will be encouraged at the age of entering school (5 to 7 years), and again on leaving (14 to 16). In a covering letter to local authorities the Minister emphasises the importance of primary vaccination in infancy. Recognising that "post-vaccinal nervous disease" has occurred mainly in children of school age or in adolescents who have never been vaccinated, he expresses the opinion that in the present state of knowledge, and so long as the small-pox prevalent in this country retains its mild character, it is not generally expedient to press for the vaccination of such persons unless they have been directly exposed to infection. The new Order makes no reference to the use of less potent lymph.

DRY LUMBAR PUNCTURE.

THE difficulties occasionally encountered in securing a sample of cerebro-spinal fluid, although the needle has been correctly passed, are examined by Dr. H. Carter in a short note contributed to the annual report of the Metropolitan Asylums Board for 1928 (p. 280). In the first place, he points out, the fluid may be pathologically thick or may be liable to clot in the needle. Secondly, there may for some reason be low local intrathecal fluid pressure. Neither of these explanations admits of much discussion. A third possible impediment—namely, lateral displacement of the theca by the needle—is set aside by Dr. Carter as improbable in view of the strong lateral and anterior attachment of the theca by the nerve roots and the common ligaments respectively. The fourth obstacle to drawing off fluid is usually described as the presence of nerve roots floating against the needle, but here again he finds the suggestion unacceptable, because the constituents of the cauda equina lack mobility. The fifth and newly recognized impediment, which he describes in the present note, is an abnormal persistence of three considerable masses of firm subarachnoid connective tissue in the theca. The chief masses are lateral and the small one is in the middle line. By the presence of these masses in the theca the cavity from which fluid is usually obtained may be reduced to one-third of its normal width. A needle is apt to be thrust into one of the lateral masses, and Dr. Carter suggests that in cases where "dry" lumbar puncture can be attributed to this cause the needle should be withdrawn and redirected so that it passes into the theca, not exactly in the middle line, but not far from it. The large lateral and small mesial masses should thus be avoided. The dissections on which the note is based were made on children, but it is possible that the abnormally persistent subarachnoid fibrous tissue may be found in a certain proportion of adults.

ON Tuesday evening, August 20th, the following bulletin was issued from Buckingham Palace:—

> The progress of His Majesty the King towards restoration of health continues. The wound is steadily diminishing in size, and is healing satisfactorily. His Majesty has derived benefit from breathing and other physical exercises. Both bodily and mental activity are now undertaken without undue fatigue. The King will be able to leave London for Sandringham in a few days.

This bulletin, which is the first to appear since July 3rd, was signed by Sir Stanley Hewett, Sir Hugh Rigby, and Lord Dawson.

MORE than 700 people have enrolled as members of the Thirteenth International Ophthalmological Congress which is to be held at Amsterdam and The Hague from Sept. 5th to 13th, and nearly 250 communications covering the branches of ophthalmology have been promised. The principal subjects of discussion will be the ætiology and non-operative treatment of glaucoma; the geographical distribution of, and international social campaign against, trachoma; and the diagnosis of suprasellar tumours. Committees will present reports on the examination of visual acuity, perimetry, the notation of the cylinder axis, the examination of light sense, the standardisation of the visual examination of railwaymen and others, and ophthalmological education. The representative of England on the International Ophthalmological Council is Mr. Leslie Paton, whilst the secretary is Dr. E. Marx, of Holland.

WE have to record the death of Dr. Fletcher Beach, consulting physician to the West End Hospital for Nervous Diseases, and at one time medical superintendent of Darenth Asylum, on August 18th, in his eighty-fifth year.

CENTRAL ASSOCIATION FOR MENTAL WELFARE.—The annual conference of this Association, which was held in London at the end of last April, was described in our columns on May 4th (p. 921 et seq.). A complete report of the proceedings has now been issued and can be obtained from the Central Association for Mental Welfare, 24, Buckingham Palace-road, London, S.W., price 3s. 6d. The conference met under the presidency of Sir Leslie Scott, M.P., and was attended by a large number of people specially interested in mental welfare and the effect of the Local Government Act, 1929, on the work of local authorities under the Mental Deficiency Acts. Among the papers read was one on the report of the special investigation carried out on behalf of the joint committee of the Board of Education and the Board of Control, contributed by Dr. A. F. Tredgold, and an address on the recommendations of that committee was given by Dr. R. H. Crowley, senior medical officer to the Board of Education.

The Clinical Interpretation of Aids to Diagnosis.

A Series of Special Articles contributed by Invitation.

XLI.—CHOLECYSTOGRAPHY.

THE object of cholecystography is to render the contents of the gall-bladder opaque to X rays so that its anatomical characteristics and physiological reactions may be studied. The normal gall-bladder is constantly receiving or discharging bile, and if a series of cholecystograms are taken at appropriate times this filling and emptying can be made visible.

Mechanism of the Test.

Broadly speaking, the mechanism of the test is as follows: A halogen compound, the one most frequently used being sodium tetraiodophenolphthalein, generally known as "the dye," is introduced into the body intravenously or by the mouth, according to the technique adopted. It is carried by the blood to the liver, through which it passes, leaving by way of the bile. In the gall-bladder the bile containing the dye is concentrated and so rendered opaque to X rays, and then after an interval is discharged down the common bile-duct. For a successful cholecystogram it is necessary to have (1) adequate absorption of the dye, (2) a permeable liver, (3) a patent cystic duct, (4) a gall-bladder able to concentrate its contents, (5) a patent common bile-duct. Full details of technique are given in recent medical text-books. Once a satisfactory technique has been arrived at, it should be scrupulously followed; in this way only is it possible to reduce mistakes to a minimum. At Ruthin Castle we get good results with a preparation known as keraphen (tetraiodophthalophenon), which has the advantage of producing small reactions. It is given orally and is not unpleasant to take.

A preliminary screening should never be omitted. With cholecystography a normal gall-bladder gives a shadow (see below), while a pathological one, into which no dye enters, may not be visible. As is well known some diseased gall-bladders also give a shadow at an ordinary screening, and if a little dye does enter such a gall-bladder during cholecystography, the shadow of the gall-bladder itself, reinforced by this small amount of dye, may give a total shadow closely resembling that seen in a normal cholecystogram.

Cholecystography gives anatomical information as to the shape, size, position, capacity, and mobility of the gall-bladder, but it is mainly a test of function and herein lies its greatest use. Pathological changes must be inferred for the most part from the disordered function and, with the important exception of stone, cannot be directly shown in the way that is possible with an opaque meal in ulcer or growth of the bowel. Even when stones are present the gall-bladder may empty and fill normally.

THE NORMAL GALL-BLADDER.

The shadow begins to appear about four hours after intravenous and 12 to 15 hours after oral administration. It gradually becomes denser and after reaching a maximum fades, shrinking at the same time. This reduction in size and density is greater after a meal is taken, especially one containing much fat. (Figs. 1 and 2.) The shadow as a rule is gone 20–24 hours after its first appearance. Such a sequence proves that the ducts from liver to gall-bladder are patent, that the gall-bladder wall is flexible and that its mucosa is healthy, and finally that the way is clear from gall-bladder to duodenum.

Anatomical Variations.

Shape and size.—The normal shadow has a smooth outline and is pear-shaped, oval or sometimes almost globular. Its size varies greatly and is much influenced by the time of the last meal.

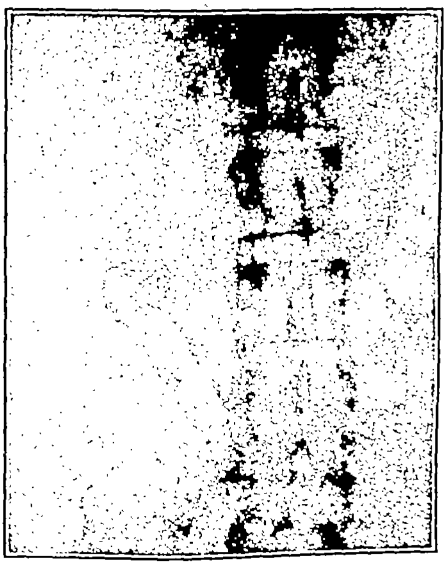
Position and mobility.—The position of the normal gall-bladder is also variable, as it may lie anywhere between the right costal margin and the right lumbar region, with almost as great a lateral swing. A range of three inches has been seen between the positions of the gall-bladder in the same patient standing and lying. This variability of position must be borne in mind, since a normally filling gall-bladder may lie in such a way as to be masked by the spine, or so that the tip of a transverse process may lie behind it and be mistaken for a stone within its lumen. The movement of the gall-bladder in various positions can be used in the differential diagnosis of opacities lying within the organ itself from those without. The anatomy of the gall-bladder also varies with the type of individual. The shadow is broader, placed higher, and moves more with respiration in those of massive build, heavy bony framework, short wide deep thorax, wide costal angle, and good bowel tone and position. In addition to general mobility within the abdomen, the range of movement in relation to neighbouring viscera is important. Here the radiologist is of great assistance by taking views from different angles, rotating or changing the orientation of patient to tube, and by the giving of a small barium meal when the gall-bladder is visible.

There are then wide variations of the normal gall-bladder, but for the most part they may be disregarded if a good shadow is obtained conforming to the emptying and filling changes noted above.

Significant Changes in the Normal Shadow.

The presence of a stone within the lumen may cause an abnormal outline and will be separately considered later. The hour-glass or biloculated gall-bladder, which is particularly liable to stone formation, may be congenital in origin or due to disease, such as adhesions, the presence of a large diverticulum, a tumour in the wall or pressure from without. My belief is that it is seldom congenital, and I would urge that a second cholecystogram should be taken before deciding that a gall-bladder is of the hour-glass type, for I have seen a bilocular shadow appear normal at a second examination. Double gall-bladders, gall-bladder diverticula, rudimentary gall-bladders, and those in which the fundus is bent up

FIG. 1.

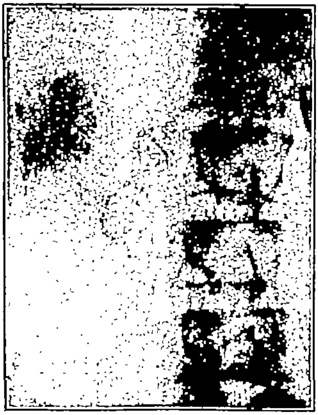


Normal shadow (oral cholecystography) filling stage.

so as to resemble a "Phrygian cap" are so rare as almost to rank as curiosities.

The normal gall-bladder should be more or less mobile, and one which does not show a fair range of movement should be regarded with suspicion, especially if highly placed, near the twelfth rib.

FIG. 2.



Normal shadow (oral cholecystography) after fat-containing meal.

A mottled shadow is generally due to stones, though it may be produced by gas in a superimposed duodenum or colon or by papillomata in the gall-bladder. When intestinal gas is present it is not confined to the gall-bladder region, and the shape of the bowel containing it can generally be made out. Multiple papillomata are rare; gritty stones lying free in the gall-bladder will change their position and arrangement with change of posture. If the stones contain enough calcium to render either periphery or centre opaque, the diagnosis is made more certain. A single stone adherent to the wall of the gall-bladder may cause an irregularity in the gall-bladder outline and be confused with an adhesion, a papilloma, or a lipoma

PATHOLOGICAL CONDITIONS.

From the standpoint of function the chief cholecystographic signs are the absence of a shadow of the gall-bladder, a faint shadow, the delayed appearance of shadow, and persistence of shadow. Of these the first two are the most important.

Absence of Shadow.

The absence of any shadow is the surest sign of a diseased gall-bladder. There may, however, even with a normal gall-bladder, be no shadow in extensive liver disease, catarrhal jaundice, acute abdominal conditions leading to temporary enlargement or œdema of the liver, and, as a rule, in the later months of pregnancy.

With these exceptions a failure to fill the gall-bladder may be regarded as due to (1) blocked cystic duct, stone being the most usual cause though growth and stricture are possibilities; (2) cholecystic disease so severe as to impair the concentrating power of the gall-bladder by destruction of mucous membrane or to fill it with calculi, mucus or inspissated bile: (3) blocked common duct due to stone or malignancy. In a series of 244 cases where no shadow appeared, which later came to operation, B. R. Kirklin[1] found a diseased gall-bladder with stones in 165, a diseased gall-bladder in 58, slight changes in the gall-bladder in 10, and a normal gall-bladder in 11, giving a total error of about 5 per cent. This raises the important and still unsettled point as to what constitutes a "diseased gall-bladder." The radiologist judges by cholecystography, which is a functional test, the surgeon by inspection and palpation, and the pathologist by the microscopic appearance of the organ. (The physician often has the unenviable task of trying to reconcile the opinions of his colleagues.)

If the 11 cases referred to above as normal gall-bladders had been removed it is more than probable that the pathologist would have supported the radiologist. I have seen a surgeon pass as normal a gall-bladder which had been condemned by the radiologist, and it was only when a "second look" was insisted on that the stones were detected which had been shown by cholecystography and were delivered when the organ was removed and opened. At present there are unfortunately no criteria applicable to all cases to indicate which is the gall-bladder whose removal will benefit the patient.

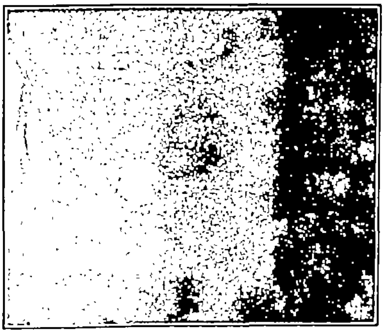
Faint Shadow. (Fig. 3.)

E. A. Graham, to whom the method of cholecystography is largely due, states of a faint shadow[2]—

> "This is but a degree of gall-bladder deficiency of which non-visualisation is the complete expression. . . . Ability to gauge the density of the gall-bladder image can only be gained by experience and observation. . . . There is no absolute scale of cholecystographic opacity because of the numerous variables that have their effect."

It is obvious that these "variables" should be reduced as far as possible by adhering closely to the chosen technique. The causes of faint shadow are those outlined above, operating to a less degree or more intermittently. As is to be expected, the degree of accuracy is not so great as with "no shadow." In Kirklin's series of 141 cases of faint shadow, 81 showed stones, 40 a diseased gall-bladder, 4 slight changes in the gall-bladder, and 16 a normal gall-bladder, an error of about 11 per cent. Even this degree of error shows greater accuracy than is possible by other means of investigation, particularly when it is remembered that "faint shadow" occurs for

FIG. 3.



Faint shadow (oral cholecystography). Two negative shadows in gall-bladder (confirmed as stones at operation).

[2] Diseases of the Gall-bladder and Bile-ducts. By E. A. Graham, W. H. Cole, G. H. Copher, and S. Moore. London, 1929.

the most part in the clinically suspicious or doubtful cases.

Other Variations.

Little is known about certain other variations from the normal seen in cholecystography. The late appearance of the shadow would be expected to follow delayed excretion of dye due to liver changes or a partial obstruction within the intra-hepatic duct system. In the gall-bladder itself a slow concentration owing to local disease would produce the same result. Even then should a shadow of normal density finally develop one should hesitate before diagnosing disease. When the shadow persists beyond the normal time the gall-bladder is rarely at fault, and other causes are to be sought, such as over-long abstention from food or reabsorption of the dye from the bowel.

Can a Diseased Gall-bladder give a Normal Shadow?

Here again we are faced with the unanswered question of what constitutes a diseased gall-bladder. In 121 cases which gave a negative response—i.e., normal shadow—Kirklin found at operation 4 cases of diseased gall-bladder with stone, 26 of a diseased gall-bladder, and 7 with slight changes in the gall-bladder, an error of about 30 per cent. He is supported by other observers, but Graham believes that "normal cholecystographic behaviour eliminates the biliary tract as the offender." My own experience is against such a definite statement. It is certain that the same gall-bladder may give a different response at different times owing to the presence of some temporary local condition at one examination. A repetition of the test is therefore advised in all doubtful cases. A professor of physiology was once asked as to what should be done when doctors differed. His reply was, "Call in more doctors." What, then, is to be done when doubt arises on the interpretation of a cholecystogram? Whether doubtful or not, it must take its place in a proper perspective with other data. Cholecystography is a test of function which may be capable of translation into terms of disease, but it cannot be allowed to replace the inferences drawn from a careful clinical examination. For example, recently in a case under our care, a bilocular gall-bladder filled and emptied normally. Operation was, however, advised on the history, when the suspected stone was found and removed, with cessation of symptoms. The history must be carefully taken and if necessary checked. This is instanced by the case of a jaundiced patient who denied all pain or even discomfort in the right upper quadrant of the abdomen. Despite this, surgery was advised, since stone was suspected. It was not till his operation, when 80 stones were found, that information was available from relatives of attacks of pain severe enough to require morphia.

Even when cholecystography indicates a diseased gall-bladder the case should be considered as a whole before treatment is decided upon. Cholecystitis is probably caused by a blood-borne infection, and there is a great possibility of disease elsewhere when the gall-bladder is involved. For this reason cholecystography should not be undertaken as a single line of investigation without due consideration of other organs. Thus, a man who showed a poorly-filling gall-bladder with multiple stones has been enabled to resume his work in comfort by clearing up a colitis which was evidently the main cause of his previous disability.

Summary.

In the presence of stone or gross gall-bladder disease cholecystography gives its most accurate results. It follows, then, that absence of shadow is the most reliable of purely cholecystographic signs and faint shadow comes next. In every instance the case must be considered as a whole before diagnosis and again before treatment. Cholecystography was devised as a test of function, and whilst it is a good servant may prove a bad master.

TREATMENT OF GENERAL PARALYSIS OF THE INSANE.

RESULTS OF MALARIAL THERAPY.

FROM the time when general paralysis was first recognised as a clinical entity the diagnosis has been regarded as almost equivalent to a sentence of death within four years. The recognition of its relationship with the *Spirochæta pallida* raised hopes doomed to early disappointment, for antisyphilitic remedies failed to give good results, and until Prof. Wagner-Jauregg introduced the malarial treatment no known form of therapy offered any prospect even of remission, much less of cure.

The Board of Control lost no time in starting an extensive test of the new remedy; they urged the superintendents of their institutions to try malarial therapy and instituted an inquiry into the results as soon as sufficient time had elapsed. The report of this inquiry is now available [1] in a form which constitutes a complete brochure on the subject of general paralysis. The history of the subject is outlined by Sir Hubert Bond in his preface, while Surgeon Rear-Admiral Meagher supplies an account of the work carried out in this country and in the various continental centres.

The Discovery of General Paralysis.

The historical introduction is a summary of Prof. G. M. Robertson's presidential address to the Royal Medico-Psychological Association in 1923. T. Claye Shaw has claimed that Shakespeare portrays a case of general paralysis in Achilles ("Troilus and Cressida," II., iii.), but the first account in medical literature was given in 1798 by John Haslam. The recognition as a clinical entity of what we call general paralysis is due to A. L. J. Bayle, who published his thesis in 1822 at the age of 23. During the two closing decades of last century the connexion of paralysis with syphilis was debated, but Sir Frederick Mott's appointment as pathologist to the London County Mental Hospitals marked an epoch in the history of the subject. His monumental volume, "Syphilis of the Nervous System," was published in 1910. The "parasyphilitic" doctrine was abandoned when Noguchi and Moore found the living spirochæte in the brain in 1913, and Mott was the first to admit that his hypothesis must give place to one which regarded general paralysis as "parenchymatous syphilis."

Malarial Treatment in this Country.

Dr. R. M. Clark, of Whittingham (Lancs), was the first English medical superintendent to induce malaria in general paralytic subjects; the date of the experiment was July 21st, 1922. In 1923 the City of London (Dartford), Rainhill, Hanwell, Bexley, Springfield (Middlesex), Claybury, Cardiff, Winwick, Chartham, Cane Hill, and Scalebor Park mental hospitals also adopted the treatment. Early in 1924 the Board of Control, assisted by Colonel S. P. James, I.M.S., of the Ministry of Health, issued a circular letter to all the institutions under their care, urging them to investigate the new remedy. Infected blood was supplied by Whittingham to other hospitals, and a mosquito centre was started at Horton. Statistics of all cases have been collected on an approved form from the outset, and Rear-Admiral Meagher, as well as collating these records, has personally visited as many of the discharged patients as possible.

To secure figures for comparison the report first reviews the fate of general paralytics in the 55 hospitals where malarial treatment has not been introduced. After correction, the total number of cases admitted during the year 1923 was found to be 624. Of these, 560 (90 per cent.) were dead at the end of 1927, while 52 (8 per cent.) were still in hospital, and 12 (2 per cent.) were living at home. All but two of those still in hospital were in the last stages of the disease. The 12 outside an institution were visited, and all were found to be mentally abnormal. One was bedridden, dirty, deluded, and incoherent; three were childishly dependent and demented; one suffered from "neurasthenia," and another from varied subjective disabilities; one had done a little work but was always ill; one did a little supervised work, and two females were able to do a little housework in their own homes. None was capable of normal occupation. This series suggests very strongly that complete recovery must be extremely rare, and that the "natural remissions," to which improvement under malaria is sometimes ascribed, are of very brief duration and poor quality.

---

[1] General Paralysis and its Treatment by Induced Malaria. Report by Surgeon Rear-Admiral E. T. Meagher, R.N. (Retd.) H.M. Stationery Office. 1929. Pp. 87. 2s.

A similar investigation of the cases admitted during 1924 shows parallel results; 88 per cent. were dead, and 284 out of 549 (51·7 per cent.) had died within a year of admission. Nineteen out of every 20 general paralytics, once certified, *remain in hospital until they die.* Complete remission lasting as long as 12 months is most rare.

Results of Malarial Therapy.

Of 152 cases treated by malaria in 1923, no fewer than 36 were living at home, and 45 in hospital, while 71 had died by the end of 1927; thus 53 per cent. were alive, as against 10 per cent. of untreated cases. Of those still in hospital 7 had improved both mentally and physically, 7 mentally only, 5 physically only but without mental regression, while 18 had degenerated mentally. Six of the discharged cases could not be traced, but the others were visited, and 17 of them were at work earning wages, 3 were capable of work but unemployed, 3 females were successfully managing their homes, 2 were able to do odd jobs, and 5 only showed signs of dementia or degeneration. None was confined to bed or to the house. A similar series for 1924 showed that of 286 cases treated 120 were dead at the end of 1927, while 94 were in hospital (50 improved both mentally and physically, 4 mentally only, 16 improved physically without mental regression, and 24 degenerated mentally). Thirty-nine of the patients at home were earning wages, while 5 were temporarily out of work; 10 were performing their usual household duties, 4 did part-time work, and 4 were unemployed for physical reasons. Five only showed progressive degeneration, and none was confined to bed.

These figures have been compiled with the utmost regard for accuracy and may be accepted without hesitation. The report goes on to consider the possible fallacies introduced by diagnosis and selection of cases. There is, however, no disparity in accuracy of diagnosis between the treated and the untreated groups, so that the comparison stands, and any selection of cases seems to have erred rather on the side of liberality than of exclusiveness. The unavoidable conclusion is that patients treated by malaria have longer lives and lead a more desirable *existence than untreated cases. If they eventually* die their bedridden stage is shorter, and the nursing staffs declare unhesitatingly in favour of malarial therapy. Of the 108 discharged cases visited, 77 were found following their previous employments, which included surveying, shorthand typing, motor-driving, shopkeeping, mill work, and farming. Naturally, they had passed through a grave illness from which some permanent damage might be expected, but many of them were able to do laborious work and live reasonably normal lives among their relatives and neighbours. The impression received from a second group was that treatment had retarded rather than eliminated the disease; their horizon seemed a little limited, and their mentality a little dull, but their friends denied any increasing childishness. When marital life had been resumed the relationship seemed to be normal and the children healthy.

Cases treated during 1925, 1926, and 1927 are reviewed, and, *although too recent to justify conclusions*, they bear out those for 1923 and 1924. Of a total of 1597 cases treated in the five years, 33·9 per cent. are dead, 40·8 per cent. in hospital, and 25·3 per cent. alive at home.

Precautions and Conclusions.

The prognosis in untreated cases would justify a grave risk in treatment; the report discusses the deaths which have followed inoculation and which may be ascribed to malaria, and points out that the period of treatment is a perilous time requiring careful nursing and control by quinine. Once the patient has survived the fever the chances are good. It is not yet possible to state definitely which method of inducing malaria is the better. Relapses are frequent (about 50 per cent.) after mosquito bite, but rare after malarial blood (2 per cent.), but they usually remit spontaneously. Wagner-Jauregg has eliminated malarial deaths by careful preliminary cardiac treatment and quinine control, and his technique may prove equally successful if introduced here. The earlier malaria is given the more favourable is the outlook, and the report emphasises the urgent need for earlier diagnosis and earlier treatment. For the best results discharged cases must be followed up and supplemental treatment supplied. With these qualifications the malarial treatment can unquestionably be accepted as a therapy of proved value and great hope. To quote the report: "In applying malaria to general paralysis, Wagner-Jauregg has found a key that moves the lock."

MEDICINE AND THE LAW.

The Liability to Give Evidence.

THE liability of a medical witness to give evidence in the county court, and the limited remuneration which he may expect for so doing, were emphasised in the Bath county court last week when his honour Judge Gwynne-James inflicted a fine of two guineas upon a practitioner who had failed to answer a subpœna to attend the court and produce the medical record of one of his patients. The judge remarked that in two recent cases he had become aware of the existence of misunderstanding upon the subject. On each occasion a medical practitioner had refused to give evidence on behalf of a patient unless paid a special fee; in one instance the special fee demanded was 20 guineas, in the other a smaller amount. Such demands, said the judge, are of no avail and cannot be enforced. If a litigant desires the presence in court of a medical or other witness, all he need do is to serve him with a subpœna together with proper conduct money. The conduct money represents the travelling expenses, if any, to and from the court; "in the case of an ordinary medical witness" there is "an extra payment of one guinea which may, in an exceptional case, be increased not beyond five guineas." When this step has been taken, the witness is obliged to appear in court and obey his subpœna. He can demand no special fee, and, if he fails to appear, he is liable for contempt of court to a fine and imprisonment.

With this statement of the law, from one of the most senior and experienced of our county court judges, there is no quarrel. The medical practitioner has his duties to perform towards the administration of justice like any other citizen, though to hang about a county court all day long may cause him inconvenience, annoyance, and definite financial loss. The position is governed by Order LIII. of the County Court Rules and the official scales of fees which, within a certain not very liberal maximum, vary with the importance of the case and the discretion of the registrar or judge. If the witness fails to attend, or, being in court, refuses to give evidence, he may be called upon to show cause why a fine should not be imposed upon him, and may then be fined if his explanation is inadequate. Possibly, if his absence was due to a summons in emergency to save life, the judge would accept it; in the recent case at Bath the absent witness had no definite reason to give; all he could say was that he had never had a subpœna before, did not appreciate what it meant, took the opinion of a friend, and absented himself. The judge accepted this frank statement as mere want of thought rather than deliberate affront to the court. As is explained in "The Conduct of Medical Practice," in criminal cases, a witness who disobeys a subpœna is liable to arrest and imprisonment. In civil cases he may be fined, and also conceivably he may be made liable in damages if the litigant can show that the case was lost for lack of the evidence which the absent witness would have given. Attendance in court, in fact, is an unfortunate necessity, and the practitioner who seeks to avoid it must foresee the possibility of litigation and do his best to stand aside at the beginning—a course which his patient's interests do not always permit. As "The Conduct of Medical Practice" points out, it is sometimes possible to make a bargain beforehand with the party concerned and thus to stipulate for a special fee; if so, this is best done before disclosing any report or memorandum of the nature of the evidence that the witness will give; for, once the litigant knows what the witness will say, he can serve his subpœna and procure the attendance in the ordinary way. It remains only to add that more and more work is constantly being placed on the shoulders of the county court judges, and that attendance in the county court may become a more frequent duty for professional witnesses. The main justification of the county court as a tribunal is—next to its speed of decision—its cheapness. It follows that county court proceedings will seldom permit the payment of substantial fees.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Amalgamation of Medical Associations.

THE annual meetings of the Hartmann-Bund and of the Ärzte-Vereinsbund were held this year in Essen. The result of these meetings was that the by-laws of both associations were amended with a view to the closer coöperation of the two associations. The Hartmann-Bund was founded some 20 years ago by the late Dr. Hartmann, of Leipzig, on the model of a trade-union, and was at first in opposition to the old established Ärzte-Vereinsbund, which was said to be not sufficiently energetic in the struggle with the sick clubs. By and by, however, the competition between both associations ceased, and notwithstanding their difference in organisation the work was divided between them; the Hartmann-Bund looked after the economic interests of the profession, whilst the Ärzte-Vereinsbund dealt with general questions such as medical ethics, medical study, and hospital questions. At the Essen meeting a thorough reorganisation was effected. While Leipzig continues to be the seat of the Hartmann-Bund, the provision that the committee must consist exclusively of Leipzig medical men is repealed as being no longer in accordance with the extension of the work of the Hartmann-Bund. It has been arranged that the president of this organisation shall ex-officio sit on the board of the Ärzte-Vereinsbund and vice versa. The situation has been still more simplified by the election of Dr. Stauder, of Nuremberg, as president of both associations. A resolution was passed against the trade tax being extended to the medical profession and against a wider application of compulsory sickness and invalidity insurance. Dr. Hellpach proposed that State insurance should be compulsory for persons earning less than 3000 M. a year, and voluntary for those earning 3000 to 6000 M., while people earning more than 6000 M. should be excluded from State insurance. Finally, the hospital question was discussed. It was stated that the number of hospital beds has increased by 71 per cent. since 1913, notwithstanding the decrease of the population by the loss of German territory after the war. In cases of illness the public more and more prefer hospital treatment to home treatment; nevertheless, private hospitals, the majority of which belong to religious corporations, cannot be maintained owing to their cost, and must be taken over by the municipalities where they are supported by public means. A motion was adopted that the appointments of hospital physicians or surgeons should not be influenced by the politics of the candidates.

Dietary Treatment of Tuberculosis.

The Berlin Medical Society lately discussed a new treatment of external tuberculosis devised by a medical man, Dr. Gerson, of Bielefeld, Westphalia. The discussion was introduced by Prof. Sauerbruch, who said that in his clinic in Munich, where he was professor of surgery until his recent appointment to the chair of surgery at Berlin University, he had made experiments on the influence of diet on the healing of wounds and of external tuberculosis. By chance he heard of a Bielefeld medical man curing tuberculosis by a special diet, and thereupon he sent his assistant, Dr. Hermannsdörfer, to that city to study the method. Dr. Hermannsdörfer, in his paper read before the Medical Society, said that the new diet was based on the following facts. Experiments on animals had proved that a protein diet reduced susceptibility to infectious diseases, whilst carbohydrates favoured tuberculosis. The liability of the body to infectious diseases depended on the amount of water in the tissues, and the limitation of kitchen salt made the tissues drier. By administration of vitamins the liability to infectious diseases could be decreased. Dr. Hermannsdörfer therefore prescribed for tuberculous patients protein and fat with a small amount of carbohydrates, and replaced kitchen salt by a salt which Dr. Gerson called mineralogen, consisting of potassium and magnesium. He further prescribed much salad and vegetables in a raw state; the quantity of grilled and boiled meat was limited. The cost of such food was 50 per cent. higher than that of the ordinary hospital diet, but the results were extraordinary. Tuberculous lesions of the bones and joints and fistulæ healed; in lupus healing was obtained within a few weeks or months, and the results were permanent, even when the diet had been discontinued. As regards tuberculosis of the lungs, a definite judgment cannot yet be given, but it is reported that Dr. Rollier has introduced the above diet in his well-known sanatorium in Leysin, Switzerland. Dr. Bommer, of Giessen University, stated that the method had been applied in the University Clinic in 200 cases of lupus with excellent success. A great sanatorium is to be opened in Wilhelmshöhe, near Cassel, for the treatment of tuberculosis according to Dr. Gerson's method and under his direction.

Country Practice in Eastern Prussia.

A correspondent to the *Berliner Ärzte-Correspondenz* gives an interesting description of the position of country practitioners in Eastern Prussia, the part of Germany beyond the Polish Corridor. Eastern Prussia is the most lonely region of Germany, the population consisting for the greater part of peasants and large landowners. Cities are rare, and a town of 30,000 inhabitants is regarded as an important city. The railway lines are few and far between, and sometimes many miles from the doctor's residence, and the traffic is small. After the war, when many newly qualified medical men returned to Germany, there was a great movement towards the country, as the towns at that time were already overcrowded with medical men. This movement has now completely stopped and many country practitioners try to go to the towns. There are several reasons: first, the *deficiency of dwellings. The country medical man* has no chances of diversion outside his home, and when his surroundings are not pleasant he tries to get away as soon as possible. In some places where the local authority has provided for adequate residence for the medical man and has let it to him at moderate prices, the result is that those posts were much sought after. Another reason is that in Eastern Prussia the income of the country practitioner is too small, a practice of 6000 M. being, as a rule, the maximum income. In some particularly lonely places, where no medical man would voluntarily settle, the Treasury has given an extra allowance of 3000 M. for a resident doctor, but this sum is too small to attract medical men because private and club practice in those deserted places is quite insignificant. A medical man who, as an exception, earns as much as 10,000 M., is not in a position to have holidays, a locum tenent for a month costing 1000 M. A motor-car, which is indispensable owing to the great distances, may be purchased by the instalment plan, but as a rule the medical man has not the means to buy another car when the old one is worn out. In Königsberg, the capital of Eastern Prussia, the local group of the Hartmann-Bund has appealed to the Königsberg medical men not yet admitted to club practice to settle in country places, but there has been no response to that appeal.

UNITED STATES OF AMERICA.

(FROM AN OCCASIONAL CORRESPONDENT.)

The International Physiological Congress.

THE International Physiological Congress is meeting from August 19th to 23rd for the first time on American soil. This is the thirteenth of these gatherings, of which the first was held at Basle in 1880, as the outcome of suggestions which found expression at the International Medical Congress in London in 1881. Since the war meetings have been held at Paris in 1920, at Edinburgh in 1923 (when German physiologists once more attended), and in Stockholm in 1926. The meeting this summer is to be held at the Harvard Medical School under the presidency of Dr. William H. Howell, director of the School of Hygiene of Johns Hopkins University.

Effects of Carbon Monoxide in Low Concentration.

When the Holland tunnel was being built in New York it became necessary to find out how much carbon monoxide is permissible in tunnel air. The research done at that time[1] has become a standard in this country for ventilating engineering, but it took account of tunnel ventilation rather from the point of view of the driver of an automobile exposed for a relatively short time than of the worker—e.g., traffic policeman or repair shop employee—who may be exposed for several hours, and members of the U.S. Public Health Service now describe[2] an investigation of effects on this latter class of worker. Exposures were made in a special chamber from four to seven hours daily over a period of 68 days to gasoline engine exhaust gas so adjusted that the mixture breathed contained at the will of the experimenters 2, 3, or 4 parts of carbon monoxide per 10,000 parts of air. Six men were subjects of the experiments. Exposure to 2 parts carbon monoxide per 10,000 air gave distinct frontal headaches in from 3½ to 4 hours in about half the exposures. No occipital headaches resulted from exposure to this concentration. In a concentration of 3 parts per 10,000 of air frontal headaches appeared sooner (2½ to 3 hours), and a few cases of occipital headache and of vertigo occurred after three hours. This concentration produced 20 per cent. carboxyhæmoglobin in the blood in 2½ to 3½ hours, and 30 per cent. in 4 to 5½ hours, depending on the subject and whether he was at rest or exercise. *At the higher concentration of 4 parts* per 10,000 parts of air the above effects were more rapidly induced. At the end of 3½ to 4 hours more than 90 per cent. of exposures resulted in frontal headaches. In general, frontal headaches appeared when the hæmoglobin was about 20 per cent. saturated. A few distinct occipital headaches accompanied by vertigo developed at 23 to 28 per cent. saturation. When the subject was breathing uncontaminated air, saturation of hæmoglobin was reduced from 35 per cent. to 5 per cent. in five hours. Inhalation of oxygen greatly increased the speed of desaturation—from 35 per cent. to less than 10 per cent. in 30 minutes. There were no apparent signs that the health of the test subjects was adversely affected by the experiments. Hæmoglobin was usually increased pari passu with an increase in the red cell count. The leucocytes were unaffected. Apart from the occasional appearance of sugar nothing abnormal was found in the urine. Significant results were not obtained by psychological tests, possibly because so few men were under observation.

Medicinal Whisky.

Although there has been a slight decrease in the average amount of liquor prescribed by each physician the number of doctors prescribing alcohol continues to show a steady increase, having risen from 48,097 on June 30th, 1927, to 69,045 on the same date this year. The amount of whisky prescribed and consumed for medicinal purposes has been somewhat over 6,000,000 gallons in the last four years. There remain some 9,000,000 gallons mostly distilled before 1917. This stock, being sufficient only for four or five more years, the Prohibition Commissioner has authorised the manufacture next year of 2,000,000 gallons of medicinal liquor to replenish the supply.

BUCHAREST.

(FROM OUR OWN CORRESPONDENT.)

Relative Intelligence of the Sexes.

Dr. Petrescu lately read a paper before the Pedagogic Society, giving the results of 15 years' observation *in the schools of Bucharest. He has found that* intelligence is about equal in the two sexes in the earliest school years. The subsequent increase in mental power is considerably more rapid among the girls, so that at the end of the school period the results of intelligence tests are all in favour of the female sex. His conclusion is that the female intellect develops more rapidly than the male, and in this he agrees with the experience of de Körösy in Hungary. But he points out that as the great work of human progress has been accomplished by males, it is fair to assume that there is an early turning point at which the intellectual activity of women is arrested.

The Katzenstein Method of Testing the Heart.

In a communication recently presented to the Medical Society of Jassy Dr. Constantinescu spoke of *Katzenstein's* method of determining the functional power of the heart—a method which holds to be of especial service before surgical operation. It is based on the observation in animals that ligature of the larger arteries results in an increased cardiac activity which is characterised by higher blood pressure without any change in the pulse-rate. This condition does not disappear until the collateral circulation is fully established after a period of several weeks. In practice the test is performed as follows. The patient lies down, and when he is quite quiet the pulse-rate and blood pressure are determined. Both iliac and femoral arteries are then compressed, and the pressure is kept up for two to five minutes, changes in blood pressure and pulse-rate at the end of that time being carefully noted. With a healthy heart acting normally there is a rise of from 5 to 15 mm. of mercury in the blood pressure, while the pulse-rate remains the same or is slightly diminished. With a hypertrophied heart a rise of from 15 to 40 mm. is observed, and the pulse remains the same or is increased. With slight cardiac insufficiency the blood pressure does not rise, and the pulse-rate is unchanged or increased; whilst a marked insufficiency shows itself by a reduction of blood pressure and an increase in the pulse-rate. The method has the advantage of being simply and easily applied, but it is necessary to guard against excitement which might affect the result.

Multiple Arterial Thrombi.

In a recent paper in *Praxis Medici* Dr. I. Sturza criticises the common diagnosis of embolism where occlusion of large vessels and sudden death occur in patients suffering from mitral lesions. He is inclined to view the process as thrombotic, on the ground that the large masses found on the vessels are often altogether out of proportion to the small and delicate excrescences upon the diseased valves. Even if thrombi are present in the left auricle, their smooth surface argues against the possibility of embolism. In a case recently under his observation the abdominal aorta from 10 cm. above the bifurcation, together with the left and right femorals, the superior mesenteric, the left renal, splenic, right pulmonary, left inferior thyroid and left carotid arteries were found filled with clot. The immediate cause of death was occlusion of the mesenteric artery, and though the patient died half an hour after the accident, the intestines were already the seat of a hæmorrhagic infarction and peritonitis was beginning. The autopsy was performed four hours after death. To decide the question of thrombosis or embolism, the walls of the affected vessels were examined microscopically and intense inflammation was discovered in them, probably set up by the entrance of bacteria into the vasa vasorum, incident to a recurring endocarditis. On this explanation, he holds, it is not difficult to understand that a thrombosis may set in as suddenly and with the same signs as an embolism. The number of vessels occluded is often surprising, but the patients may have relatively few symptoms.

Public Health Services.

REPORTS OF SCHOOL MEDICAL OFFICERS.

Name of district.	No. on roll.	Average elementary school attendance.	No. of routine children examined.	No. of special examinations and re-inspections.	Percentage of children found on routine examination requiring treatment.†
Bootle ..	11,807	10,613	3,631	14,578	22·4
Leeds ..	75,150	—*	21,817	77,569	32·7

Ilford ..	14,910	—*	5,910	9,795	28·6

* Not given. † Excluding dental defects and uncleanliness.

Bootle.

Dr. F. T. H. Wood, of Bootle, calls attention to the progress and expansion of the school work made possible by the increasing interest and coöperation of parents and teachers. Special inspections have risen from 4790 to 5280, largely owing to the attendances at the rheumatism clinic established early in the year; over 60 per cent. of the sources of reference at the special inspections were direct requests from the parents. Dr. Wood stresses the value of the attendance of parents at the routine inspections. He believes that the education of parents in sound nutrition and domestic care, the improvement of facilities for the drying of clothing of children arriving wet at school, the provision of dry dwellings, and prompt early attention to chills and illness such as tonsillitis will all play an important part in the conquest of rheumatism. He notes that 84 per cent. of all the skin diseases were due to conditions closely associated with uncleanliness and that nearly 3000 school days were lost by exclusion indirectly due to the same cause; the annual cost to the ratepayers of the inspection and treatment of uncleanliness in school-children was at least £300. He is convinced that the source of infection of all habitually verminous children is the home and not the school, and that if further progress is to be made it must be through education of the parent. On the subject of dental treatment he holds that the surprising difference in the conditions of the children's teeth and in the number of consents given for treatment among schools of similar standing can only be explained by the varying degrees of interest and enthusiasm shown by teachers, who are also urged to devote attention to the prevention of flat-foot, which mostly begins in later childhood. He draws attention to the importance in this connexion of (1) avoidance of muscular fatigue in the growing child and provision for ample sleep; (2) supervised training of the whole muscular system, especially that of the legs; (3) ordering a proper type of boot, which should be so fashioned that the inner side of the boot is kept straight and the end of the boot opposite the big toe; and (4) teaching the child to walk and stand with feet kept parallel and not pointed outwards. In walking the child should rise on the balls of the toes with each foot in succession.

Dr. A. G. Williamson, the assistant medical officer, analyses 111 of the first cases of rheumatism seen at the clinic. He states that no new features have come to light. The great majority of the cases started between the ages of 5–12, and that as the heart was so often affected in insidious and unsuspected cases the value of the clinic was emphasised. The spread of scalp ringworm was also inquired into, and in the 18 cases closely investigated the infection was not of school origin—a feature that is in harmony with the keynote of Dr. Wood's report, that the most important influence on the child is to be found in the home.

Leeds.

Dr. A. Wear notes the changes in the 20 years since the first report on the school medical work was issued; the work in general has increased in extent and efficiency, while the special work has come to include orthopædic treatment with massage and artificial sunlight, X rays, clinics for ear, nose and throat, eyes and skin, and searching ascertainment, registration, and administrative action for exceptional children. The clinic work began in one top room with one nurse (Miss Webster), who to-day superintends the school nursing service of Leeds (covering nearly 320,000 patients every year), of which she was once the sole representative. Owing to the indefatigable work of the nurses, with the help of the teachers, the presence of lice and nits, almost inevitably found in these early days, has become "distinctly rare." There is now a generally improved physique and more careful dental and general cleanliness, and the establishment of a health conscience, particularly among the girls, is becoming noticeable. On the value of fresh air in elementary schools Dr. Wear is emphatic. He cites two otherwise similar schools; one with better ventilation had a percentage of 6·5 cases of infectious illness, another less well ventilated had a percentage of 13·7. It is surprising that the report contains no direct reference to the lack of an open-air school. This lack is the more striking because the percentage of defects found is unusually high (32·7 per cent.) which reflects both thorough medical inspection and adverse local conditions. There may be some local factor which explains this omission, nowadays very rare. Provision seems to be made for all exceptional children apart from the delicate and pre-tuberculous class, and it is especially this class which benefits so much from prophylactic treatment. There are special schools for the physically and mentally defective, for the blind and the deaf, and there is a nursery school. For anæmia, rickets, malnutrition, and tuberculous conditions artificial sunlight treatment has been available since June, 1927, and recently these facilities have been improved. Dr. Wear comments on the low earning capacity of the ex-pupils of the special mental deficiency schools, and thinks that more attention should be given to manual training, and he also suggests that a larger proportion of scholars might be allowed to leave school for *suitable* employment after reaching the age of 14. But would not, however, this system defeat its own object? The child leaving at 14 usually gets into a blind alley job from which he is turned away at 16 when his employer is faced with payments under the Insurance Act. He is then workless, untrained, and unsocialised, and for the defective lad the moral and social outlooks are deplorable. If this possibility were borne in mind in the interpretation of the phrase suitable employment this danger might be avoided, but the number of children finding permanent work would be small. Improvement is to be hoped for along the other lines indicated in this report—better manual (semi-vocational) training continued until 16 years of age, and close coöperation with the employment exchanges.

Despite the immense amount of routine work time has been found for some special inquiries, and for propaganda in the best sense of that word—including the award of prizes for the child with the best cared-for teeth and for the best essays on the subject.

Stockport.

Dr. N. Gebbie draws attention to the fact that in Stockport, as elsewhere, the number of children found to be suffering from defects at the very beginning of their school life is still unduly high, and suggests that it is to a more complete supervision of the infant and the toddler by means of an extended maternity and child welfare service that we must look for improvement. This conclusion is not altered by the circumstance that the percentage of defects at later ages does not differ greatly from that of the entrants, for many defects may persist and others are revealed—e.g., errors of refraction—as school life progresses. But the care of the toddler is not so much in the province of the infant welfare centre as in that of nursery schools, the universal and adequate provision of which is an ideal not yet likely to be attained. They do not exist in Stockport, and it is not indicated in the report how far the facilities of the school clinics are made use of for infants below school age. A considerable extension of the dental work has been made possible by the appointment of an additional dentist in August, 1928. There have been inspections in 20 schools, compared with six in the previous year. Steps have also been taken to reduce the number of casual cases, though six sessions per week out of 24 are reserved for treatment of urgent necessitous cases. A complete orthopædic scheme has not yet been established, but good work is being done by means of a special arrangement with the Stockport Infirmary, and the interest taken in the welfare of the crippled children by Mr. E. S. Brentnall, the hon. orthopædic surgeon of the infirmary. The facilities provided include massage, exercises, and artificial sunlight treatment. Some beds are allotted at the infirmary to school-children, and cases are also sent to the Shropshire Orthopædic Hospital at Oswestry. It has been decided to provide an open-air school at Woodbank, where there is an ideal site, with accommodation on modern lines for approximately 100 children. Three class-rooms of the open-air type are in use in a temporary building at Flyde Lodge High School. A voluntary organisation known as the "George Fearn Trust," aided by a grant of £150 from the local authority, maintains 15 beds at the Ormerod Convalescent Home at St. Anne's-on-the Sea. There is no organiser of physical training, but in the elementary schools this training is given by teachers who have paid special attention to the subject, and in the secondary schools for girls remedial exercises when required are discussed by the visiting doctor with the drill instructor. Owing to the prolonged illness of the specialist teacher the class for stammering children could not be held. It is evident that the work in Stockport, as far as the facilities allow, has been thoroughly carried out.

Margate.

Margate is one of those smaller places where practically all the general work is done by one person. Dr. Cowan McCombe has to turn his mind from large engineering questions like main water-supply to smaller ones like the cure of blepharitis or the giving of an anæsthetic, and constantly has new duties to face such as the care of rheumatic children and the licensing of nursing homes. He has help in the special branches of dental, aural, and ophthalmic work, and his burden is lightened by the nurse (there is apparently only one full-time nurse) and by the sanitary inspectors. He has also the coöperation of the attendance officer and the teachers, to all of whom he gives especial thanks. It is perhaps because Dr. McCombe is known so well personally that the percentage of parents attending the medical inspections is unusually high—nearly 80 per cent. Another feature of a small area with good local interest is the large share taken by voluntary bodies; the provision of meals for necessitous cases is carried out independently of the authority, and the occupation class for the ineducable mentally defective was run privately. The risk attached to such voluntary service was made obvious when the lady responsible for this class was unable to continue and it had to be dropped at least temporarily. This is the more unfortunate because there is no home for mentally defective children in Kent, and it is almost impossible to get institution treatment for them. Another disadvantage of areas of this size is the impossibility of establishing any local special schools; use has to be made of joint or borrowed accommodation. The education authority has recently coöperated with the county council in the orthopædic scheme. The clinic is held at Broadstairs, where an orthopædic surgeon attends twice a month and a trained nurse weekly. Hospital accommodation is provided in suitable cases and surgical appliances are supplied for out-patients when necessary. There are 65 delicate children who would benefit from an open-air school, but this, unfortunately, does not exist.

Ilford.

Dr. A. H. G. Burton, whose school medical report was again one of the earliest to appear, shows clearly what has been done in Ilford and what extensions of activity are essential. The authority has established an adequate and well-planned open-air school to which 90 children have already been admitted. It is designed to allow the maximum amount of sunlight and air into the class-room, the whole of which can be opened on the south side by folding doors. Arrangements have been made for the conveyance of those who live in outlying parts of the borough. The next step forward will be the establishment of an orthopædic scheme, which is not a very easy matter owing to the position and size of Ilford. Coöperation with the Essex County Council has been considered, but the nearest centre is at Romford which is too far for Ilford children to attend. The nearest hospital at which there is an orthopædic surgeon is in London. The authority would therefore need (1) to make arrangements for in-patient orthopædic treatment in London; (2) to appoint an orthopædic surgeon whose salary would be some 80 guineas a year if he attended fortnightly; and (3) to establish and fit up clinics for massage and remedial exercises with a whole-time trained masseuse at a salary of £200. At present valuable remedial exercises are being carried out for postural defects and slight deformities by Mr. F. T. Roberts, the supervisor of physical training, whose interesting report is here included. Extended facilities for dentistry are much needed. The present scope of the work is very limited, and the low percentage of acceptances (45·9 per cent.) should be raised when the appointment of a second dentist makes it possible to undertake educational propaganda among the parents and children.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED AUGUST 10TH, 1929.

Notifications.—The following cases of infectious disease were notified during the week: Small-pox, 114 (last week 129); scarlet fever, 1482 (last week 1776); diphtheria, 741; enteric fever, 80; pneumonia, 612; puerperal fever, 28; puerperal pyrexia, 81; cerebrospinal fever, 8; acute poliomyelitis, 16; acute polio-encephalitis, 2; encephalitis lethargica, 14; continued fever, 1; dysentery, 10; and ophthalmia neonatorum, 81. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the Metropolitan Asylums Board on August 13th–14th was as follows: Small-pox, 132 under treatment, 5 under observation (last week 134 and 9 respectively); scarlet fever, 1326; diphtheria, 1491; enteric fever, 18; measles, 330; whooping-cough, 276; puerperal fever, 27 (plus 13 babies); encephalitis lethargica, 123; and "other diseases," 23. At St. Margaret's Hospital there were 12 babies (plus six mothers) with ophthalmia neonatorum.

Deaths.—In the aggregate of great towns, including London, there were no deaths from small-pox, 3 (1) from enteric fever, 28 (5) from measles, 1 (0) from scarlet fever, 25 (6) from whooping-cough, 33 (6) from diphtheria, 60 (5) from diarrhœa and enteritis under two years, and 15 (4) from influenza. The figures in parentheses are those for London itself.

Of the deaths from measles 5 were reported from Liverpool and 5 from Bradford; those from diarrhœa and enteritis included 6 each from Manchester and Liverpool, 5 each from Birmingham and Sunderland, 4 each from Hull and Stoke-on-Trent, and 3 each from Leeds and Newcastle-on-Tyne.

The number of stillbirths notified during the week was 305 (corresponding to a rate of 49 per 1000 total births), including 59 in London.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—From Sept. 9th to 14th the Brompton Hospital will hold an all-day course in diseases of chest. Facilities will be given for attending the practice of the various departments of the hospital, and instruction will be by lecture and demonstration. Under Dr. Eric Pritchard's direction there will be a course at the Infants Hospital from Sept. 9th to 22nd. This is designed mainly for those engaged in infant welfare work, and visits will be paid to centres other than the hospital. From Sept. 10th to Oct. 5th a course of lecture-demonstrations in psychological medicine will be given at the Bethlem Royal Hospital on Tuesday and Saturday mornings. An intensive course in medicine, surgery, and the specialties for men only will be given at the Westminster Hospital from Sept. 16th to 28th, from 10.30 A.M. until 5.30 P.M. daily. The Prince of Wales's Hospital and the North Middlesex Hospital will hold a course in gastro-enterology from both medical and surgical aspects from Sept. 30th to Oct. 4th. The Metropolitan Hospital will hold its first course under the auspices of the Fellowship, in medicine, surgery, and the specialties, from Oct. 21st to Nov. 2nd. A second evening course for the M.R.C.P. examination from Oct. 15th to Dec. 6th. Further information and syllabuses may be had from the Secretary of the Fellowship at 1, Wimpole-street, London, W. 1.

Obituary.

WILLIAM EWART, M.D. CAMB., F.R.C.P. LOND.,

CONSULTING PHYSICIAN TO ST. GEORGE'S HOSPITAL.

WE announced last week the death, on Sunday, August 11th, in his 81st year of Dr. William Ewart. This will have come as no surprise to those who knew him, since for several years he had been in a very precarious state of health; but in spite of his increasing general weakness and his painful lameness he remained until the end a familiar figure in the Athenæum, and a regular attendant at the Comitia of the Royal College of Physicians of London.

DR. WILLIAM EWART.

[Photograph by Elliott and Fry.

William Ewart was the son of an English father and Xenie Guillet, a French lady, and he was educated partly in England and partly at the University of Paris, where he obtained the diploma of Bac. ès Lettres. He joined the medical school of St. George's Hospital in 1869, and as a student saw service with the French army in the Franco-German war. He obtained the diplomas of the English Colleges in due course, becoming house physician to the hospital in 1873. In the following year he took the diploma of M. R. C. P. Lond., and in 1875 was elected house physician to Addenbrooke's Hospital, Cambridge, at the same time gaining at Gonville and Caius a scientific scholarship. In 1876 he graduated in the first class of the Natural Science Tripos, and proceeded to the degree of M.B., which he obtained in 1877. After some post-graduate work in Berlin he returned to St. George's Hospital as curator of the museum, lecturer on physiology, and demonstrator of physiological chemistry, was appointed pathologist to the hospital in 1879, and in 1882 was elected assistant physician. He had previously taken to the M.D. Camb., and been elected F.R.C.P.

Ewart's connexion with St. George's Hospital was a long and honourable one. He was assistant physician for seven years, during which time he was assiduous in the conduct of out-patient practice, and an informative if whimsical demonstrator of the varied clinical material which came under his eye. Many students of St. George's will remember Ewart's demonstrations, for they formed a curious difference from anything like stereotyped teaching in their rapid deductions and explanations and their alternate brevity and diffuseness. Patients, also, were often disconcerted by his methods of cross-examination—he was not really trying to convict them of inaccuracy, but his questions were often oddly worded, while he seemed impatient at the delay or confusion in the replies brought about by his own use of words. But those who attended the out-patient department regularly under Ewart's direction learned much clinical medicine. In 1888 he was elected full physician to the Hospital, and discharged his duties with regularity and enthusiasm, although again his teaching was of an individual character that often appeared unpractical to his pupils. While assistant physician to St. George's Hospital he had also been assistant physician to the Brompton Hospital for Consumption and Diseases of the Chest, and this post, in accordance with a rule that seemed prevalent at the Hospital at that date, he was asked to resign upon election as full physician to St. George's. Ewart had been a very energetic pathologist at Brompton, and acquired a great deal of knowledge concerning phthisis, where he had been in touch with much modern work, so that it was natural that in his wards at St. George's he should be particularly interested in pulmonary cases. His physical examination of such patients was minute and laborious, and many of his clinical clerks must have been hard put to it to recognise the various signs of stationary, active, and new mischief which he would detect. He was constantly on the look-out for rare cases, and it sometimes seemed as though his high scientific equipment as a student betrayed him into associating with elaborate chemical or physical reactions circumstances which could be explained in more ordinary fashion.

Especially did Ewart's work at Brompton, although of no long duration, influence his literary interests. His most important literary work was entitled Pulmonary Cavities, and was an expansion of the Goulstonian Lectures on the subject which were delivered in 1882 before the Royal College of Physicians of London. In the course of an elaborate explanation of the methods, as he saw them, by which nature endeavours to heal pulmonary cavities, he referred in great detail to the anatomical changes which bring about the formation, collapse, contraction, and healing of these lesions, and the knowledge of the subject which he displayed—alike of the post-mortem findings and the literature—was recognised at once as remarkably intimate and well documented. He pursued the subject later in a volume upon the anatomy and nomenclature of the bronchi and pulmonary blood-vessels, while the articles on bronchitis and bronchiectasis, which he contributed to Allbutt and Rolleston's System, again revealed his deep interest in the structure of the lung. A second side of Ewart's activities was due to his experience gained at Brompton, for the influence on the tuberculous subject of climatic conditions led him to study climatology in a practical manner, and to write notes on the climatic features of various centres at home and abroad at a time when such information was badly needed.

Ewart's connexion with the Royal College of Physicians of London was a long and intimate one. Elected a Fellow in 1881, at the time of his death he was fourth or fifth on the roll of seniority. He delivered the Goulstonian Lectures in 1882, as has already been said, acted as an examiner for two separate periods of three years—1885 to 1888, and 1894 to 1898, and was a member of the Council from 1901 to 1903. To the end of his life he was a devoted servant of the Corporation, and a very regular attendant at the Comitia, where he will be sadly missed.

In practice, apart from his hospital work, William Ewart did not possess the qualities that appealed to the public, nor was he able to render the prompt and straightforward assistance to family practitioners that they and their patients expected at consultations. And thus it came about that William Ewart, with great scientific qualities and personal characteristics that endeared him to many, made no headway at all as a consultant physician.

WE have to record that Dr. JAMES DOUGLAS WRIGHT, of Wembley Park, has died suddenly at Chichester from pneumonia in his forty-fifth year. Born at Coatbridge, he was educated at the Anderson College and St. Mungo's College, Glasgow, where he qualified with the Scottish conjoint diploma in 1912. Throughout the late war he served in France, holding a captain's commission in the Royal Army Medical Corps. A period of post-graduate study at Glasgow followed, and in 1921 he became a Fellow of the Royal Faculty of Physicians and Surgeons. As a practitioner in Wembley Park he was not very widely known, but his considerable skill as a physician was appreciated, and colleagues with whom he was intimate found that they were wise in turning to him for advice when in difficulties. His kindness to his patients was reflected in their loyalty to him and his death will be much regretted. Dr. Wright was unmarried.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Capt. T. B. Shaw relinquishes his post as Professor of Hygiene and Director of Medical Studies at the Naval Medical School, Greenwich, on appointment to Chatham Hospital. Surg. Capt. J. S. Dudding succeeds Surg. Capt. Shaw.

Surg. Lt. A. A. Pomfret to be Surg. Lt.-Comdr.

The following appointments have been notified:—Surg. Capts. A. R. Schofield and C. T. Baxter to *Vivid;* and L. M. Morris to *Victory*, for R.N. Hospl., Haslar. Surg. Lts. W. R. S. Panckridge to *Nelson;* and J. L. Malone to *Alecto*

ROYAL ARMY MEDICAL CORPS.

Capts. J. M. Savoge and G. K. Fulton to be Majs.

The undermentioned Lts. (on prob.) are confirmed in their rank: J. C. Gilroy, W. A. R. Ross, D. Blewitt, R. G. G. Robertson, V. C. Verbi, W. H. Scriven, J. Crosley, H. E. Knott, and M. J. Malley.

TERRITORIAL ARMY.

Capt. D. R. Jones to be Maj.

Lts. D. G. Coutts and G. A. MacDonald to be Capts.

F. W. A. Warren and N. Harkness to be Lts.

E. G. C. Darke and C. R. Croft (late Offrs. Cadet, Univ. of Lond. Contgt., Sen. Div., O.T.C.) to be Lts.

Capt. J. B. McGovern resigns his commn. and retains his rank.

TERRITORIAL ARMY RESERVE OF OFFICERS.

Lt.-Col. C. Rundle having attained the age limit relinquishes his commn. and retains his rank.

Maj. W. J. Gray having attained the age limit retires and retains his rank, with permission to wear the prescribed uniform.

Capt. (Bt. Maj.) G. Patton and Capt. F. W. Begg having attained the age limit relinquish their commns. and retain their rank.

ROYAL AIR FORCE.

Major R. H. Bebb (Army Dental Corps) is granted a temporary commission as a Squadron Leader (Dental) on attachment to the R.A.F.

Flight Lt. A. B. H. Cole (Capt. Army Dental Corps) relinquishes his temporary commission on return to Army duty.

TERRITORIAL DECORATION.

The King has conferred the Territorial Decoration upon Majs. P. E. Barber (retd.), G. H. H. Waylen, W. George, and A. H. Fullerton, and upon Capt. J. B. McGovern (retd.).

COLONIAL MEDICAL SERVICES.

Dr. P. S. Selwyn Clarke, from the West African Medical Staff, has been made Assistant Director of Sanitary Service, Gold Coast. The following appointments have been made: Dr. A. G. Badenoch, Dr. G. I. H. Braine, and Dr. R. C. Burgess, Medical Officers, Federated Malay States; Dr. B. A. S. Russell, Lady Medical Officer, Gold Coast; Dr. H. S. Begbie, Assistant Medical Officer of Health, Hong-Kong, and Dr. W. D. Forrest, Medical Officer, Hong-Kong; Dr. R. M. Dowdeswell, Dr. M. A. W. Roberts, and Dr. H. C. Trowell, Medical Officers, Kenya; Captain N. L. Joynt, Medical Officer, Virgin Islands, Leeward Islands; Dr. S. Kramer, Assistant Colonial Surgeon, St. Helena; Dr. E. K. Tratman, Professor of Dental Surgery, College of Medicine, Singapore; and Dr. D. C. McE. Macpherson, Medical Officer, Gilbert and Ellice Islands, Western Pacific. Dr. C. R. Adgie and Dr. S. A. Maclean have been appointed Medical Officers on the West African Medical Staff.

"Audi alteram partem."

MEDICAL WORK AT THE SCOUTS' JAMBOREE.

To the Editor of THE LANCET.

SIR,—I think that the profession in general would like to know about the important part which many of its members played in the World Jamboree at Birkenhead. From home or overseas, some 70 doctors were in camp. They represented almost every branch of the profession—consultants, practitioners, medical officers of health, the services, teaching staffs, research, specialists, and students. Many are high in the Scout movement, many are actively associated in furthering its aims; some not desiring a "busman's holiday" were to be found in important non-medical appointments at the Jamboree, and were always ready to give their professional services when required; while others, non-Scouters, stood in to lend a hand in hospital or aid-post out of sheer goodness of heart. Years did not signify; among all, there was joy in their actions and the spirit of youth on their faces. It is delightfully refreshing to see eminent medical men in the boyish and rational dress of shirts and shorts. Medical necks and medical knees take on a fine shade of tan. And the spirit of comradeship and friendliness that sprang up was perfectly splendid. A medical Scouters' dinner was held, at which almost 50 were present. The Chief Scout received the members of the health organisation (hygiene and medical staffs) on the last day of the Jamboree and expressed his great appreciation of the work they had done for Scouting.

It is fine to see so many members of our profession imbued with the spirit of scouting. For myself, it was a unique privilege to observe how magnificently they carry into practice the Scout doctrine of service to others.—I am, Sir, yours faithfully,

M. B. H. RITCHIE,

Major, Royal Army Medical Corps; Assistant Jamboree Camp Chief (Health), World Jamboree, 1929.
Military Hospital, Colchester, August 19th, 1929.

*** *An annotation on medical work at the camp appears on p. 396.*—ED. L.

THE TREATMENT OF HÆMORRHOIDS.

To the Editor of THE LANCET.

MY DEAR DOCTOR,—I highly esteem your magazine, THE LANCET, and am thoroughly grateful for space accorded the review of my book, "The Modern Treatment of Hæmorrhoids." It grieves me, however, to see my book misquoted in great length in the aforesaid review. May I ask you, therefore, to allow me the privilege of correcting these errors and misquotations and of making one or two remarks pertinent to the matter discussed in this review?

First, I am quoted as "still preferring a 20 per cent. solution of cresylic acid, glycerine and water." The fact of the matter is that I have never preferred nor advocated a 20 per cent. solution of this substance. What I *have* recommended and what I *do* use is a 10 per cent. solution. Since the trend of popular opinion is toward the weaker strength in injection treatment solutions, I feel that my book may be misjudged by the aforementioned statement that I prefer the 20 per cent. solution.

Secondly, I am quoted as recommending the use of a suction pump for the diagnosis of hæmorrhoids, when, in fact, my book discusses at some length the possibility of harmful effects upon the patient incident to its use and emphasised the fact that clinical judgment in the matter may be distorted by its employment. I trust you will permit me to quote my concluding sentence in this respect. I say, "We are thus liable to do the patient the injustice of ascribing to him a pathological condition, hæmorrhoids, when, in fact, what is observed as merely a normal physical response to a physical state of negative pressure." From this it must be very evident that I regard the method just as obsolete as your revewing authority does. I am, therefore, loathe to be classed among those that recommend it. Unfortunately the review does place me in that category.

Two other points that I think will bear mention are that the reviewing editor in chiding me for the lack of "facts about recurrence-rate" overlooks the fact that I have devoted one entire chapter of nine full pages to a discussion of the very subject concerning whose omission he is so deeply grieved. Finally, he deplores the lack of metric recommendation as to the dosage to be employed in the injection treatment. The instructions I do give are such as require observation during the administration of the treatment. I do believe these to be far more reliable and definite than any mathematical formula. If the good doctor will exclude all the variable factors which individuals present, will standardise the size of hæmorrhoids, their composition and consistency, and, moreover, will standardise the reaction of the tissues to the solutions we use in injection, then I will be in a position to make a specific mathematical formula which will resolve the injection treatment of hæmorrhoids into a simple process of turning a crank.

I trust you will be so good as to give as much space to this partial refutation of the review of my book as you gave to the original review. I assure you this will be greatly appreciated.

Most cordially yours,

New York, July 22nd, 1929. J. F. MONTAGUE.

*** We much regret the error as to the strength of the solution of cresylic acid. In reviewing the first edition of the work we recorded the strength of the solution correctly. With regard to the use of the suction pump, lest readers should put our reviewer's interpretation on the passages referred to, would it not be as well to much curtail in future editions reference to this technique: a lengthy and illustrative description of a measure may surely be read as a recommendation? With regard to the recurrence-rate, the statements require more detailed support in the form of definite facts, while the practitioner would certainly be much helped by information about average doses and usual limits of dosage.—ED. L.

THE ANGLO-FRENCH LIBRARY OF MEDICAL AND BIOLOGICAL SCIENCE.

To the Editor of THE LANCET.

SIR,—The kindly notice in this week's LANCET of Sir William Hamer's "Epidemiology, Old and New" (1928) emboldens me to draw attention to a project that has hitherto escaped comment. This book, and Sir Humphry Rolleston's "Aspects of Age, Life and Disease," are the first contributions, by English authors, to a series of monographs, by French, British, and American writers of distinction, that will be known as the Anglo-French Library of Medical and Biological Science. The original feature of this collection of books is that *each* volume will be published in London in English and in Paris in French. Thus, translations of the books written by Sir William and Sir Humphry are actually on the point of publication in Paris, whilst one of Prof. Achard's, "L'œdème brightique" (ready in Paris) is now in the hands of the printer in London. That a French and an English publishing house should have collaborated to this end, in the manner found possible by Messrs. Doin and Messrs. Kegan Paul and Co., is, in itself, gratifying to all those who desire to forward the exchange of ideas between members of the medical profession in the two countries. I confess to being jealous that the reception accorded to the plan in England should not be less generous than that reported to me by my co-editor, Prof. Cruchet, of Bordeaux.—I am, Sir, yours faithfully,

F. G. CROOKSHANK.

Wimpole-street, W., August 17th, 1929.

THE NEW VACCINATION ORDER.

THE new Vaccination Order, framed on the Report[1] of the committee (the Rolleston Committee) appointed in conjunction with the Medical Research Council, was issued by the Ministry of Health at the beginning of the week, together with a circular addressed to boards of guardians.

THE STATEMENT OF THE MINISTER OF HEALTH.

The Vaccination Orders will be amended especially to give effect to the following recommendations of the Rolleston Report, which will be found on p. 201 of that document:—

(1) In place of the officially advocated four insertions a trial be made of vaccination and revaccination in one insertion with a minimum of trauma, and that multiple scarification and (or) cross-hatching be deprecated.

(2) Primary vaccination be performed in infancy, between the ages of 2 and 6 months as at present, and revaccination be offered at the time when a child enters school (5 to 7 years), and again on leaving (14 to 16 years).

(3) Vaccination in multiple insertions be available for such persons as desire to obtain the maximum protection against small-pox obtainable at one operation.

(4) In public vaccination parents be informed that if, in consequence of vaccination, a child requires medical attention, it is the duty of the public vaccinator concerned to provide such attention without cost to the parents.

The Minister has issued a new Order to boards of guardians dealing with these points, with a detailed explanation of certain paragraphs in the Order, contained in the first schedule which gives the official instructions to public vaccinators. Thus stress is laid upon the recommendation numbered (3) above, ensuring that where the parent or guardian of a child desires maximum protection the number of insertions may be increased up to four.

Post-vaccinal Nervous Disease.

Of post-vaccinal nervous disease, concerning which the Rolleston Report stated that though the manifestation might be extremely rare their occurrence must be of serious import, the Minister of Health says: "Post-vaccinal nervous disease, both in this country and abroad, has occurred mainly in children of school age or adolescents who had never previously been vaccinated, and that this fact emphasises the desirability of securing the successful vaccination of infants. Where this has not been attained the question which arises is whether it is advisable to vaccinate children of school age or adolescents. The Minister is of opinion that, in the present state of knowledge, and so long as the small-pox prevalent in this country retains its present mild character, it is not generally expedient to press for the vaccination of persons of these ages who have not previously been vaccinated, unless they have been in personal contact with a case of small-pox or directly exposed to small-pox infection."

THE VACCINATION ORDER, 1929.

After the preamble, according to form setting out references to existing vaccination orders, the new Order sets out an amendment of paragraph 0, Form A, in the schedule to the Order of 1924 which ensures after-inspection by the public vaccinator both of any vaccination performed by himself or a medical practitioner to give the necessary certificate of successful operation. Where he is himself the operator he is to render any subsequent treatment required. A further paragraph sets out that revaccination, which is stated to be desirable at the ages of 5 and 14, will be performed free of cost on application to the public vaccinator.

Instructions to Vaccinators under Contract: the First Schedule.

(1) Except so far as any immediate danger of small-pox may require, the public vaccinator must vaccinate only subjects who are in good health. As regards infants, he must ascertain that there is not any febrile state, nor any irritation of the bowels, nor any unhealthy state of the skin, especially no chafing or eczema behind the ears, or in the groin, or elsewhere in folds of skin. He must not, except of necessity, vaccinate in cases where there has been recent exposure to the infection of diseases such as measles, scarlatina, or diphtheria, nor where erysipelas is prevailing in or about the place of residence.

(2) *If it be necessary to postpone vaccination on medical* grounds a certificate to that effect must be given by the public vaccinator in the form prescribed by the Minister of Health or to the like effect—

(*a*) If in his opinion the child is not in a fit and proper state to be vaccinated; or

(*b*) If in his opinion the child cannot be safely vaccinated on account of the condition of the house in which it resides or because there is or has been a recent prevalence of infectious disease in the district; and in any such case the public vaccinator is required forthwith to give notice of such certificate to the medical officer of health of the district in the Form P. set out in the Fifth Schedule to this Order,[2] or to the like effect.

(3) All public vaccinations are to be performed with glycerinated calf lymph or with such other lymph as may be issued by the Minister of Health. If the parent or other person having the custody of the child requires that it shall be vaccinated with lymph issued by the Minister of Health, the vaccination must be performed with such lymph.

(4) The public vaccinator must keep such record of the lymph he uses for vaccination as will enable him always to identify the origin of the lymph used in each operation. He must not employ lymph supplied by any person who does not keep an exact record of its source.

(5) The public vaccinator must keep in good condition the lancets or other instruments which he uses for vaccinating, and he must not use them for any other purpose whatever. When vaccinating he must have with him the means of sterilising and cleansing his instruments. He must cleanse and sterilise his instruments immediately before and after performing each vaccination. When once he has unsealed a tube of lymph he must never attempt to keep any part of its contents for the purpose of vaccination on a future occasion. In no circumstances whatever should the mouth be applied directly to the tube in which the lymph is contained for the purpose of expelling the lymph. In the case of ordinary capillary tubes an artificial blower may be properly used for this purpose.

(6) Vaccination should at every stage be carried out with aseptic precautions. These should include: First, the thorough cleansing of the surface of the skin before vaccination; secondly, the invariable use of sterilised instruments; and thirdly, the effective protection of the vaccinated surface against extraneous infection both on the performance of the operation and on inspection of the results.

Advice should always be given to the person having the custody of the child as to the necessity of effective protection of the vaccinated surface until the scabs have fallen and the arm has healed.

(7) In all ordinary cases of vaccination or revaccination, the public vaccinator should vaccinate in one insertion preferably by a single linear incision or scratch not more than a quarter of an inch long merely through the epidermis. This incision should be made in the long axis of the limb. The lymph may be applied to the cleansed skin and the incision made through it, or the lymph may be applied to the incision immediately after the latter has been made. The lymph may be gently rubbed into the scratch with the side of the needle or lancet. In cases in which the public vaccinator or the vaccinee (or the parent or other person having custody of a child vaccinee) desires to obtain additional protection at one operation (i.e., where the maximum protection against small-pox is desired, or where the circumstances make it especially desirable to avoid risk of failure), the public vaccinator may, if he considers it necessary, increase the number of such insertions. The number of insertions should not exceed four, and they should be placed so as to avoid coalescence of the resulting vesicles. The aim of the public vaccinator should be to produce successful vaccination with the minimum of injury to the tissues. In no circumstances should the vaccinated area be cross-scarified or cross-hatched.

---

[1] Cmd. 3148, H.M. Stationery Office. 1s.

[2] i.e., The Vaccination Order, 1898.

Opportunity should be taken by the public vaccinator to recommend that, in view of single-insertion vaccination, revaccination is advisable at an earlier period than if more insertions had been made than one.

(8) The public vaccinator must enter all cases in his register on the day when he vaccinates them, together with all particulars required in the register up to and including the column headed "Initials of person performing the vaccination." The results of the vaccination are to be entered in the register upon the day of inspection and attested by the initials (in column No. 13) of the person who makes the inspection. In cases of successful *primary* vaccination the public vaccinator must record the number of separate normal vaccine vesicles or groups of vesicles which have been produced. In cases of *revaccination* he must register as "successful" only those cases in which either vesicles, normal or modified, or papules surrounded by areolæ, have resulted.

When any operation (whether vaccination or revaccination) has to be repeated owing to want of success in the first instance it should be entered as a fresh case in the register.

The new Order comes into force on Oct 1st, 1929.

Medical News.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—The Council of the College are prepared to receive applications for the office of Milroy Lecturer for 1931 on State Medicine and Public Health. Particulars will be found in our advertisement columns.

ROYAL COLLEGE OF SURGEONS OF ENGLAND: *Examination in Canada.*—A Primary Examination in Anatomy and Physiology for the Fellowship of the College was held at Toronto on August 6th and the following days, this being the first occasion on which this examination has been held out of England. The examination was conducted by Profs. William Wright, W. E. Le Gros Clark, C. Lovatt Evans, and John Mellanby, who were sent out from England for the express purpose, with Profs. J. P. McMurrich and C. H. Best, of Toronto University, as assessors. Sir Holburt Waring also attended as visitor on behalf of the College. Twenty-three candidates presented themselves for examination and nine were successful. The Canadian Medical Association was responsible for the arrangement, and much of the success of this new departure was due to Dr. Alexander Primrose, Dean of the Medical Faculty of the University of Toronto, and Dr. T. C. Routley, General Secretary of the Association, who took an active part in bringing about this attempt to offer to Canadian medical practitioners greater facilities for obtaining the F.R.C.S. Eng. There is a strong desire in Canada for closer association between the medical profession in the Dominion and in this country, and much interest has been taken in Canada and the United States in the undertaking. The examiners were received by the Governor-General at Quebec, and by the Prime Minister at Ottawa, who expressed sympathetic interest in their mission. The Final Examinations for the Fellowship will be conducted only in England, but the opportunity of passing the Primary Examination in Canada should make two visits to this country unnecessary, and so, it is hoped, bring the F.R.C.S. Eng. within the reach of a larger number of Canadians than has hitherto been the case.

INSTITUTE OF HYGIENE.—On August 16th a luncheon was held on the premises at 28, Portland-place, London, W., to celebrate the granting of a Royal Charter of incorporation to this Institute which was founded in 1903. In the absence of Sir Thomas Oliver, the President, the chair was taken by Prof. J. W. H. Eyre, a Vice-President, who spoke of the work done over a long period in persuading manufacturers to provide unsophisticated food and drink and good clothing, and in trying to improve conditions of life generally. Prof. Bostock Hill, in proposing the toast of the Institute, referred to the work of the National Health Week Committee over which he had presided for 18 years. Dr. Harry Campbell responded to the toast; Dr. Andrew Balfour proposed the health of the Chairman; Mr. A. L. Peterson spoke of the value of the Institute from the point of view of the manufacturer; and Mr. Seymour Harding, the Secretary, responded to the toast of his health.

DEGREES AND DIPLOMAS IN PUBLIC HEALTH.—The Royal Institute of Public Health has issued a booklet describing the course of instruction which it offers to candidates for these degrees and diplomas. It may be had from the Secretary of the Institute, 37, Russell-square, London, W.C. 1.

UNIVERSITY OF MELBOURNE.—Dr. R. Marshall Allan, M.C., has been appointed professor of obstetrics in the University. At one time Assistant Master of the Rotunda Hospital, Dublin, he has been director of obstetric research at Melbourne University for the past two years. He is a graduate of Edinburgh University and a Fellow of the Edinburgh Royal College of Surgeons.

ST. THOMAS'S HOSPITAL MEDICAL SCHOOL.—The following awards have been made for 1929–1930: A University Scholarship to John Bishop Harman, of St. John's College, Cambridge; Entrance Science Scholarships to C. J. Cobbe and to S. H. Alavi and R. H. R. Belsey; and a William Tite Scholarship to H. R. B. Norman.

GIFT FOR VETERINARY RESEARCH.—The Government of New South Wales has accepted a gift of £20,000 from Mr. F. D. McMaster for the erection of an animal health laboratory by the Scientific and Industrial Research Department.

THANK-OFFERING FUND.—The Fund being raised to commemorate the recovery of the King now stands at about £400,000. Of this sum £187,000 is contributed to the National Radium Fund, whilst the remainder, which is received by King Edward's Hospital Fund for London, includes amounts which have been ear-marked for individual hospitals.

Appointments.

DAVIES, L. M., M.D., B.Ch. Oxf., D.P.H., has been appointed Medical Officer of Health, Devon.

MACDONALD, E. K., M.D., B.S. Lond., Medical Officer of Health, Barnsley.

WEAVER, A. E. REMMETT, M.D., Ch.B. Birm., D.P.H., Medical Officer of Health for the Weston-super-Mare Urban district.

Certifying Surgeons under the Factory and Workshop Acts: PICKELS, J. A., M.B., B.S. Lond. (Uffculm District, Devon), and SARAFIAN, D. H., L.R.C.P. Lond., M.R.C.S. (Chipping Sodbury, Gloucester).

Vacancies.

For further information refer to the advertisement columns.

Birkenhead General Hospital.—Cas. S. £100.

Birmingham City Education Committee.—Asst. School M.O. £600.

Bradford, Municipal General Hospital, St. Luke's.—H.P.'s and H.S.'s. Each at rate of £200.

Bristol Royal Infirmary.—H.P. to Cancer Research Dept. At rate of £60.

Chester Royal Infirmary.—H.S., &c. £120.

Coventry and Warwickshire Hospital.—Hon. Anæsthetist.

Evelina Hospital for Children, Southwark, S.E.—H.S. £120.

Exeter, Royal Devon and Exeter Hospital.—Asst. H.S. At rate of £100.

Freemasons Hospital and Nursing Home, 237, Fulham-road, Chelsea, S.W.—Res. M.O. At rate of £250.

Great Yarmouth General Hospital.—Sen. H.S. £150. Also Secretary £300.

Hospital for Tropical Diseases, Endsleigh-gardens, W.C.—Two H.P's. Each at rate of £150.

Hospital for Women, Soho-square, W.—Res. M.O. At rate of £100.

Hull Royal Infirmary.—Cas. H.S. Also Asst. H.P. Each at rate of £130.

Kidderminster and District General Hospital.—H.S. £150.

Kingston-upon-Hull, City and County of.—M.O.H. £1500.

King's Lynn, West Norfolk and Lynn Hospital.—Sen. and Jun. H.S.'s. £150 and £100 respectively.

Lanarkshire Joint Committee on Venereal Diseases.—Venereal Diseases O. £750.

Leicester Royal Infirmary.—H.S.'s, H.P. Also Cas. O. Each at rate of £125.

Liphook, Hants, King George's Sanatorium for Sailors.—Asst. M.O. At rate of £200.

Liverpool University.—Lecturer in Pathology. £600.

Liverpool and District Hospital for Diseases of Heart.—H.P. At rate of 50 guineas.

London Jewish Hospital, Stepney Green, E.—Cas. O. At rate of £150.

London Temperance Hospital, Hampstead-road, N.W.—Cas. O. At rate of £120.

Lowestoft and North Suffolk Hospital.—H.S. £150.

Maidstone, Kent County Ophthalmic and Aural Hospital.—Aural H.S. At rate of £200.

Manchester, Ancoats Hospital.—H.S. At rate of £100.

Manchester Royal Children's Hospital, Gartside-street.—Two Asst. M.O.'s. Each at rate of £150.

Manchester Royal Children's Hospital, Pendlebury.—Res. M.O. At rate of £125.

Mount Vernon Hospital, Northwood, Middlesex.—H.S. At rate of £200.

Nottingham General Hospital.—H.P. Also Asst. Res. Cas. O. Each at rate of £150.

Oswestry, Shropshire Orthopaedic Hospital and Agnes Hunt Surgical Home.—H.S. £200.

Prince of Wales's General Hospital, Tottenham, N.—Hon. Anaesthetist.

Rotherham Hospital.—H.P. £180.

Royal College of Physicians.—Milroy Lecturer for 1931.

Royal National Orthopaedic Hospital, 243, Great Portland-street, W.—H.S. also H.S. for Country Branch, Stanmore. Each at rate of £150.

Royal Northern Hospital, Islington Tuberculosis Dispensary, Holloway, N.—Tuberculosis Officer. £750.

St. Marylebone Hospital, Ladbroke-grove, W.—3rd Asst. M.O. £300.

St. Peter's Hospital for Stone, &c., Henrietta-street, Covent-garden, W.C.—H.S. At rate of £75.

St. Vincent's Orthopaedic Hospital, Eastcote, Middlesex.—Res. M.O. At rate of £150.

Scarborough Hospital and Dispensary.—Two H.S.'s Each at rate of £120.

Sheffield City.—Asst. Tuberculosis Officer. £600.

Sheffield Royal Infirmary.—Jun. Aural and Ophth. H.S. At rate of £80. Also Clin. Asst. for Ophth. Dept.

Southampton, Royal South Hants and Southampton Hospital.—Jun. H.S. Also Cas. O. At rate of £130 and £120 respectively.

Tipton Urban District Council.—M.O.H., &c. £800.

Torquay, Torbay Hospital.—Hon. P. Also H.P. £175.

Wakefield, West Riding Mental Hospital.—Jun. Asst. M.O. £400.

Watford, Herts Peace Memorial Hospital.—Res. M.O. At rate of £150.

Weir Hospital, Grove-road, Balham, S.W.—Sen. and Jun. Res. M.O.'s. £200 and £150 respectively.

Weston-Super-Mare General Hospital.—H.S. £130.

Worcester General Infirmary.—Sen. and Jun. Res. M.O.'s. £180 and £120 respectively.

The Chief Inspector of Factories announces a vacancy for a Certifying Factory Surgeon at Freshford (Somerset).

The Secretary of State for the Home Department gives notice of a vacancy for a Medical Referee under the Workmen's Compensation Act, for the Districts of the Eastbourne and Hastings County Courts (Circuit No. 50). Applications for the post should reach the Private Secretary, Home Office, not later than Sept. 4th.

Births, Marriages, and Deaths.

BIRTHS.

JAIDKA.—On August 8th, at "Newcroft," Eastfield, Peterborough, the wife of K. C. Jaidka, F.R.C.S.E., of a daughter.

SCOTT.—On August 7th, at Fletcher House, Tottenham, N., the wife of Dr. J. A. A. P. Scott, of a daughter.

MARRIAGES.

BELLAMY—MCGREGOR.—On July 30th, at St. Bartholomew's the Great, E.C.1, William Albert Bellamy, M.R.C.S., L.R.C.P., to Elsie, youngest daughter of the late C. M. McGregor and Mrs. McGregor, of Plumstead.

DAUKES—BIGGS.—On August 10th, at the Presbyterian Church of England, Hove, Lieut. H. W. Daukes, R.A.M.C., to Olive Margaret, eldest daughter of Mr. and Mrs. Owen O. Biggs, of Sackville-gardens, Hove.

RUSSELL—BREW.—On August 12th, at St. Augustine's Church, Penarth, Arthur Victor Russell, M.B., to Mary Violet, eldest daughter of Dr. and Mrs. Richard W. Brew, of Penarth, South Wales.

DEATHS.

BEACH.—On August 18th, at De Crespigny-park, Denmark Hill, Fletcher Beach, M.B. Lond., F.R.C.P., M.R.C.S., L.S.A., aged 81.

BUCKLEY.—On August 8th, at Clopton Manor, Kettering, Northants, Thomas William Buckley, M.D. Durh., M.R.C.S. Eng., J.P., Major, late R.A.M.C., aged 70 years.

SPENCE.—On August 12th, in a London nursing home, John Buchan Spence, M.B., aged 73.

WHITE.—On August 7th, suddenly, at Juan les Pins, Herbert White, M.R.C.S., L.R.C.P., late Surgeon Lieut. Com., R.N., in his 46th year.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

ARTIFICIAL CREAM: A PROSECUTION.

THE Artificial Cream Act, passed last May and taking effect at the beginning of June, was a measure pressed forward rather in the interests of agriculture than of public health. It is, nevertheless, worth while to note that the first prosecution under the Act occurred at Marlborough-street police station on August 13th when the Ferns Pure Milk and Cream Company was fined sums amounting to £10 2s. with £7 costs for a breach of the statute.

The Act defines "cream" as "that portion of natural milk rich in milk fat which has been separated by skimming or otherwise," and "artificial cream" as "an article of food resembling cream and containing no ingredient which is not derived from milk except water or any ingredient or material which by virtue of the proviso to Subsection (2) of the Food and Drugs (Adulteration) Act, 1928, may lawfully be contained in an article sold as cream." The statute makes it an offence to sell or offer for sale for human consumption under a description or designation including the word "cream" any substance purporting to be cream or artificial cream within the statutory definition unless (*a*) the substance is cream as defined in the Act, or (*b*) where the substance is artificial cream as defined in the Act, the word "cream" is immediately preceded by the word "artificial." The defendant company said its artificial cream was made out of the constituents of dairy cream and nothing else. A Government analysis stated that it was reconstituted cream with a low fat content. It was two-thirds the price of ordinary cream. There had been some misunderstanding about the label. The magistrate, who remarked that the very name of the company was misleading, said that the Act was no good unless it was enforced. The label, even when affixed to the carton, was misleading; there was nothing about artificial cream until the receptacle was turned round, and then the words were upside down. The artificiality of the substance ought not to be concealed but should be more prominent than anything else.

The prosecution was undertaken by the National Farmers' Union, but it may be noted that the Act casts upon the local food and drugs authorities the duty of enforcing its provisions. All premises where artificial cream is manufactured, sold or exposed for sale for human consumption must be registered with the local authority unless already registered under other provisions. The public will doubtless appreciate the opportunity of distinguishing a natural from a synthetic article of food.

ATOPHAN ADMINISTERED BY INUNCTION.

IN many European schools it is becoming fashionable to give drugs by the skin. Alimentary disturbances, both immediate and remote, may thereby be avoided, and apart from comfort and consequences it is naturally an advantage to avoid the chance that the remedy will disintegrate in the stomach. Many drugs damage the liver when given by mouth, and it is claimed that this trouble is largely obviated by using the cutaneous route. The difficulty of absorption is, of course, often great. Volatile bodies, for instance, are not nearly so readily absorbed by the skin as by the lungs or alimentary tract. Alkaloids, again, are very uncertain in their penetration, whatever the vehicle, and aqueous solutions of non-volatile drugs hardly pass through the skin at all. But a good many drugs mixed with oil, fat, or alcohol—in short, anything capable of mixture with, or permeation through, the extracutaneous film of grease and the cutaneous fat—seem to be absorbed consistently and rapidly. This has led Prof. H. Kionka,[1] of Jena, to try inunction as a means of administering atophan, a trade preparation of phenyl-cinchoninic acid, which has come in for a certain amount of criticism on account of its toxic action on the liver in certain cases. Like other quinoline carbonic derivatives, atophan is said to have the curious power of reducing the ability of the renal tubules to reabsorb urates. When they are taken by mouth a considerable increase in the urinary excretion of all the urates is seen. The body tissues and the articular structures in particular are depleted of uric acid and the clinical amelioration of gout may be brought about. Kionka gave the drug to rabbits in two different forms, the first being an ointment composed of vaseline and olive oil as the vehicle; and the second a commercial preparation called Doloresum-tophiment, in which the atophan exists as an amino compound and the vehicle is a soap fat. The efficacy of the commercial preparation was found to be double that of the crude ointment as measured by the quantitative urinary excretion of uric acid. This heightened activity is attributed to the soap fat basis.

---

[1] Fort. d. Ther., 1929, v. 173.

It will be remembered that the question of the toxicity of phenyl-cinchoninic acid was fully discussed in our own columns not long ago by Dr. Geoffrey Evans and Dr. A. W. Spence.[2]

BIRTH CONTROL.

AT the Population Conference at Geneva in September, 1927, a body was formed called the International Medical Group for the Investigation of Birth Control. The second annual issue[3] of their report, which is now obtainable, contains contributions from six different countries, those from Great Britain and the United States being the longest. The papers are for the most part written according to a common plan, the headings of which are: Statistical investigations, research work of a relevant kind, information about the general temper of the country towards birth control, and "miscellaneous remarks."

The section most likely to prove interesting to English medical readers is the one which concerns Great Britain, written by Dr. C. P. Blacker. In this article an attempt is made to summarise what is known statistically of the value of different contraceptive methods. These are found to be less effective than is generally assumed. The data analysed are those of certain birth control clinics. Among patients with whom the clinics maintain touch, the various methods taught are found in one way or another to be unsatisfactory by a percentage that ranges from 9 per cent. (Walworth) to 24 per cent. (North Kensington). Among patients with whom the clinic fails to maintain contact, a small number of whom were visited in their homes by a social worker of the North Kensington Clinic, the percentage is higher. In the United States the method which is thought the most reliable, and which is most usually taught, is a combination of pessary and spermaticidal jelly. The follow-up system that prevails in the American clinic, whose figures are analysed, is very thorough. It is interesting, therefore, to note that for this combination of methods, as taught in America, the "failure rate" is only 5 per cent. It is acknowledged that the figures on which the British percentages are based are inadequate. A satisfactory system of keeping case records has only been evolved after much experience and thought, and the early records from which the percentages have been extracted are both incomplete and unsatisfactory. Even so, however, the figures give cause for disquietude. Nevertheless the report as a whole is encouraging in that it foreshadows the possibility of great improvement in contraceptive technique as a result of certain research now in progress.

The report attempts to appraise impartially the value of contraceptive methods in use in different countries, and to summarise medical information about birth control as it becomes known in different countries. In view of the great sociological importance of contraception it is possible that future reports may have considerable influence both at home and abroad.

ULTRA-VIOLET RAYS IN OPHTHALMOLOGY.

THE positive and negative indications for the use of ultra-violet rays in diseases of the eye are defined in a recent paper by Mr. W. S. Duke-Elder.[4] Tuberculous iridocyclitis, he says, is especially suitable for general light treatment combined with tuberculin, and another disease in which its value is very great is phlyctenular keratoconjunctivitis. In chronic cases, especially when general light baths are used in association with local application of light, the disease can almost invariably be overcome, although corneal opacities once formed may be permanent. The more important part of Mr. Duke-Elder's paper concerns the local application of ultra-violet rays, for which he has devised a special ophthalmic radiation lamp. Many inflammatory and degenerative affections of the anterior segment of the eye are amenable to this treatment, but it is essential that it should be undertaken only by specially skilled hands, since an error in the focusing might easily cause permanent injury to the lens. For this reason it is only suitable for diseases of the cornea, iris, sclera, and conjunctiva. Pathogenic micro-organisms are killed, also the superficial cells of damaged corneal epithelium, and an intense vascular reaction floods the diseased cornea with bactericidal influences. Almost any kind of corneal ulcer, including hypopyon ulcer, responds well to the treatment. In mild affections the usual therapeutic methods may be sufficient without exposure to ultra-violet rays, but in severe and recurrent cases it is invaluable. The method is also indicated in sclero-keratitis and in some conjunctival affections, which fail to improve under ordinary measures; among these Mr. Duke-Elder includes trachoma but not spring catarrh. For applying the rays to the upper conjunctival fornix he has devised a special form of application to be used with his lamp.

HOLIDAYS FOR FACTORY GIRLS.

To the Editor of THE LANCET.

SIR,—You have on many other occasions shown your sympathy with factory girls in need of a holiday, and have earned their sincere gratitude by allowing us to appeal through your columns to the generosity of your readers. May we again, in circumstances of urgency, invoke your friendly aid? In heat such as we have experienced lately in our crowded towns, one longs more than ever for a dip in the sea or for a breath of air on the hills; for meals out of doors, lunch in a bathing suit on the sands, a picnic tea under the shade of the trees. Whatever indeed the weather may be, one looks forward throughout the year to the summer holiday, for many the only appreciable holiday, in the hope that it will bring respite and rest and renewal of health.

Some of your readers will know of hopes for a holiday frustrated, of plans long made brought to nought at the last moment. Those who have not been so unfortunate can at least imagine the bitter disappointment caused by the loss of a holiady long due. Such a disappointment will assuredly fall to many tired workers in factories this summer unless your readers, to whose generosity we appeal, are able to come to the rescue. Many factory girls who have done their best to make some provision for a holiday by putting aside their pence throughout the year, are waiting to go away; but the funds which seek to supplement their savings are exhausted. We ask your readers to replenish them.

The help thus given is accepted with lasting gratitude. It blesses those who give and those who take. Many letters, written by the girls in a spirit of deep thankfulness and describing the varied delights of a change of air and scene, testify eloquently to this. Quotations from such letters may be seen in the report of the fund. The fund helps chiefly the poorest class of factory workers. It helps those who, being often the main support of their families, are quite unable in this matter adequately to help themselves. They need this summer holiday, and one has only to see them before and after it to realise what wonders such a holiday can work.

Subscriptions and donations will be thankfully received and acknowledged by the hon. treasurer, Mrs. Slater, or Miss Canney, 75, Lamb's Conduit-street, London, W.C. 1.

We are, Sir, yours faithfully,

(Signed) ALBERTA SANDWICH,
KATHERINE ATHOLL,
A. F. LONDON,
W. PETT RIDGE,
ANNE SLATER (Hon. Treas.).
J. FREDK. GREEN (Chairman).

75, Lamb's Conduit-street, London, W.C. 1,
August 16th, 1929.

A DISCLAIMER.

To the Editor of THE LANCET.

SIR,—Reference an article in your issue of August 10th headed "An Ingenious Truss," describing an apparatus manufactured by the Uterpress Co., and named by them the "Colquhoun" truss, I should be glad if you will publish this, which is to the effect that I have no interest in the name, manufacture, or sale of the truss mentioned.

I am, Sir, yours faithfully,
GIDEON COLQUHOUN, F.R.C.S.

44, Brook-street, W., August 20th, 1929.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, QUEEN-SQUARE.—Last year 1464 in-patients were treated at the hospital itself, at the Convalescent Home at East Finchley, and at Lonsdale House, Clapham, the branch for disabled sailors and soldiers. The cost of maintenance was £39,177, which exceeded the income by £4795. The board are anxious for the preservation of Queen-square House Garden, since the amenities of the hospital would be seriously affected if it were built over.

STUDENTS' GUIDE—SESSION 1929-1930.

GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION OF THE UNITED KINGDOM.

POWERS, DUTIES, AND CONSTITUTION.

THE General Council of Medical Education and Registration of the United Kingdom is, first, a registering body: no person, even though his qualifications have been obtained by examination, is a *legally qualified* medical practitioner until his name appears on the Medical Register. Secondly, it is a standardising body, ensuring that medical education reaches an efficient minimum standard by scientific examination. Thirdly, it is a penal and disciplinary body, having power to remove from the Register any practitioner convicted of felony or misdemeanour or adjudged guilty of professional misconduct. Fourthly, to the Council is committed the codification of pharmaceutical remedies. The duties of the Council are thus primarily of a public nature, and its construction shows its fitness for its fourfold responsibilities.

The Council consists of 38 members, of whom all but 11 are official representatives of some corporate body. Five members are chosen by the Crown on the advice of the Privy Council, and six others are elected by the members of the medical profession as Direct Representatives. The Crown members need not be medical men and one layman now sits on the Council. Three members are appointed for dental business by the Privy Council under the Dentists Act, 1921, under which the powers and duties of the General Medical Council with regard to the keeping of the Dentists Register and the administration of the Dentists Acts were largely transferred to the Dental Board of the United Kingdom.

THE EDUCATIONAL CURRICULUM.

Professional Education.—The course of professional study after registration as a student occupies at least five years. The Final Examination in Medicine, Surgery, and Midwifery must not be passed before the close of the fifth academic year of medical study.

Regulations as to Registration of Medical Students.

Before registration as a student every candidate should produce evidence that (*a*) he has attained the age of 17 years; (*b*) that he has passed a recognised examination in general education; and (*c*) that, *in addition thereto*, he has passed, or obtained exemption from, an examination, theoretical and practical, in elementary physics and elementary chemistry conducted or recognised by a licensing body. The minimum standard of General Education required is that of University Matriculation or entrance examination in the Faculties of Arts or Pure Science. In other Faculties the examination must be of the standard prescribed in Regulation 2 below.

An approved course of instruction in elementary biology at a secondary school or other teaching institution recognised by a licensing body may admit a student to the professional examination in elementary biology upon registration as a medical student.

The candidate commencing medical study should apply to the registrar of the division of Great Britain and Ireland in which he is residing, according to a prescribed form, copies of which may be had on application to the several licensing bodies, medical schools, and hospitals, or at the offices of the Council; and should produce proof that he, or she, has fulfilled the first three conditions.

The Maintenance of the Register of Medical Students.

1. The Education Committee prepares and issues from time to time a list of examining bodies whose examinations in general education fulfil the conditions of, and are specially recognised by, the Council.

2. The Council has recognised the undernoted university examinations which are conducted in Great Britain and admit to the Faculties of Arts or Pure Science, or to other Faculties, subject to the conditions specified below:—

Oxford University, Responsions; Cambridge University, The Previous Examination. The Matriculation Examinations of the following Universities: Birmingham, Bristol, Durham, Leeds, Liverpool, London, Victoria of Manchester, Sheffield and Wales, and the Entrance or Preliminary Examination of the Universities of Scotland.

The condition prescribed by the Council in Faculties other than Arts or Pure Science is that:—

The certificate shall bear evidence that the candidate has passed in the Matriculation or Entrance standard, in the following subjects, viz.: (a) English. (b) Mathematics, Elementary. (c) A language other than English. (d) A fourth subject, as defined in the regulations of the particular Examination, to be chosen from the subjoined list, viz.: History, Geography, Physical Science, Natural Science; Latin, Greek, Hebrew, French, German, or other language accepted by the University for the purpose of matriculation or entrance.

3. Subject to the condition prescribed above (Section 2), the Council will recognise those of the examinations conducted by recognised authorities in Great Britain which are accepted by any one or more of the above-named Universities as equivalent (under prescribed conditions as to "credits" or "grades"), for purposes of Entrance or Matriculation, to an Examination named in the preceding list (Section 2). Such Examinations are:—

Bristol University: Higher School Certificate Examination; School Certificate Examination. Cambridge Local Examinations Syndicate: Higher School Certificate Examination; *School Certificate Examination. Central Welsh Examination* Board: Higher Certificate Examination; School Certificate Examination. Durham University: Higher Certificate Examination; School Certificate Examination. London University: Higher School Certificate Examination; General School Examination. Northern Universities Joint Matriculation Board: Higher Certificate Examination; School Certificate Examination. Oxford and Cambridge Schools Examination Board: Higher Certificate Examination; School Certificate Examination. Oxford Delegacy for Local Examinations: Higher School Certificate Examination; School Certificate Examination. Scottish Education Department: Leaving Certificate Examination.

4. The Council will continue to recognise certain Examinations conducted by Educational Bodies, other than those (mentioned in Section 3) whose Examinations are accepted by any one or more of the Universities of Great Britain. Recognition will not be extended under this Section to any Examination unless the Council is satisfied (*a*) that in scope and standard it is equivalent to a recognised Matriculation or Entrance Examination of a University of Great Britain, (*b*) that it fulfils the condition prescribed by the Council (Section 2), and (*c*) that the Examination has been completed at not more than two sittings. Such Examinations are:—

The College of Preceptors (England): Senior Certificate. The Educational Institute of Scotland: Preliminary Medical Certificate.

5. Subject to the prescribed condition (Section 2), the Council will recognise the Entrance Examination to the School of Physic of the University of Dublin, and the Matriculation or Entrance Examinations of the National University of Ireland, the Queen's University of Belfast, the Irish Royal Colleges of Physicians and Surgeons; and also the Leaving Certificate of the Department of Education of the Irish Free State, the Senior Grade Leaving

Certificate of the Ministry of Education of Northern Ireland, and all examinations accepted by any one or more of the Universities of Great Britain or Ireland, as equivalent, for purposes of entrance or matriculation, to the above-named University Examinations.

6. Subject to the prescribed condition (Section 2), the Council will recognise all Examinations of Colonial or Foreign Universities which are accepted by any one or more of the Universities of Great Britain as equivalent, for purposes of entrance or matriculation, to an examination named in the list of examinations recognised by the Council (Section 2).

7. The Council will recognise the Final Examinations for Degrees in Arts or Science of any University of Great Britain or Ireland or of the British Dominions.

8. The registration of medical students shall be placed under the charge of the Branch Registrars.

9. Each of the Branch Registrars shall keep a register of medical students.

10. The Branch Registrar shall enter the student's name and particulars in the Students Register, and give him a certificate of such registration.

11. Each of the Branch Registrars shall supply to the several licensing bodies, medical schools, and hospitals, in that part of Great Britain or Ireland of which he is Registrar, blank forms of application for the registration of medical students.

12. A copy of the Medical Students Register prepared by each of the Branch Registrars shall be transmitted, on or before Dec. 31st in each year, to the Registrar of the General Council, who will distribute the list to the licensing bodies, medical schools, and hospitals.

All applications for special exceptions to the foregoing regulations as to registration shall be addressed to the Registrar of the General Council, and shall be decided by authority of the Education Committee, who shall report thereon to the Council.

The Medical Schools and Colleges.

The Universities, including their Colleges and Medical Schools, and Schools of Medicine at which Medical Study may be commenced in the United Kingdom are set out seriatim in the following pages.

MEDICAL REGISTRATION IN IRELAND.

The problem of medical registration in the Irish Free State, which gave rise to some anxiety a short while back, has been satisfactorily settled. By agreement between the Governments of Great Britain, of the Irish Free State, and of Northern Ireland — since confirmed by legislature at Westminster and Dublin—the powers and duties of the General Council of Medical Registration and Education are to continue as heretofore in respect of qualifying bodies in the Irish Free State, and of medical practitioners qualified in the Irish Free State. Side by side with this a Medical Council has been set up in the Irish Free State with the duty of establishing and controlling a Register for the Irish Free State. Practitioners whose names are on the General Register, and persons who pass a qualifying examination in the Irish Free State, will be registered on the Irish Free State Register on payment of the prescribed fee. The Irish Free State Medical Council have, over those whose names are on the Irish Free State Register, the same disciplinary powers as are possessed by the General Council over those whose names are on the General Register. To possess the privileges of a qualified practitioner in the Irish Free State it is necessary to be registered in the Irish Free State Register.

The net result of the change in the law as regards the practitioner qualifying in the Irish Free State in the future is that: (1) If he intends to practise only in the Irish Free State he need only register in the Irish Free State Register; (2) if he intends to practise in Great Britain he will register in the General Register; and (3) if he is in doubt where he will practise he will register in both Registers. He will, as he registers in one Register, or in both Registers, put himself under the disciplinary control of the one Council or of both Councils. No practical inconvenience is caused, and practitioners qualified in the Irish Free State in future will not find themselves deprived of any of the privileges or rights enjoyed by their predecessors.

THE DENTAL BOARD OF THE UNITED KINGDOM.

Anyone who is on the Medical Register is entitled to practise as a dentist, although he cannot register as such without degree or licence in dentistry; but it is a distinct advantage to take a special dental qualification, otherwise few dental appointments at general or special hospitals or dispensaries are available, and, unless registered in the Dentists Register, no dental work, under the additional Benefit Scheme of the National Health Insurance Act can be undertaken.

Under the Dentists Act, 1921, the powers and duties of the General Medical Council under the Dentists Act, 1878, and under the Medical Act, 1886, which related to the keeping of the Dentists Register and the administration of the Dentists Acts were largely transferred to the then newly constituted Dental Board of the United Kingdom. The registration of dental students at the commencement of their dental studies, and the right of erasure of a name from the Dentists Register, remain with the Council, but the duty of inquiring into disciplinary cases rests with the Board, upon whose recommendations the Council acts.

The Dental Board consists of a chairman and 12 members. The chairman is appointed by the Privy Council. Other members of the Board are appointed by the Minister of Health, the Scottish Board of Health, the Governor-General of Northern Ireland, the General Medical Council (3), Direct Vote of the qualified dentists practising in England and Wales, Scotland, and Ireland (3), Direct Representatives by registered dentists not being qualified dentists (2).

Registration of Dental Students.

The General Medical Council's Regulations in regard to the registration of dental students which came into force on Jan. 1st, 1923, provide that the registration of dental students shall be carried on at the General Medical Council Office in London, in the same manner as that of medical students, and be subject to the same regulations as regards age and preliminary examinations; but in the case of dental students professional study may commence either at a recognised dental hospital or school, or by pupilage with a registered dental practitioner.

Candidates for a diploma in dental surgery should produce certificates of having been engaged for at least four years in professional studies, and of having received during 24 calendar months instruction in dental mechanics. It is recommended that instruction in dental mechanics be taken at a recognised dental hospital and school. If any part of such instruction be taken by the candidate as a pupil with a registered dental practitioner, the time required to be devoted to it shall be at least twice the time required for the corresponding instruction taken at a dental school. Two years' *bona-fide* apprenticeship with a registered dental practitioner, after registration as a dental student, may be counted as one of the four years of professional study. When a student can show evidence of regular pupilage in dental mechanics to a registered dental practitioner, prior to the passing of the prescribed preliminary and scientific examinations, he may be allowed to antedate his registration for a period not exceeding one year prior to the passing of these examinations.

THE OFFICES.

The address of the Registrar, to whom further communications should be addressed, is as follows: The Registrar of the General Medical Council. 44, Hallam-street, Portland-place, London, W. 1, The offices of the Dental Board are adjoining.

A memorandum on the procedure to be adopted by those who desire to enter the profession of medicine, with notes on costs and prospects, and a similar Memorandum in regard to Dentistry, may be obtained on payment of 1s. each.

THE

MEDICAL EXAMINING BODIES

AND

SCHOOLS OF THE UNITED KINGDOM.

A GUIDE TO THE FACILITIES FOR OBTAINING THE VARIOUS MEDICAL DEGREES AND OTHER QUALIFICATIONS FOR THE BRITISH MEDICAL REGISTER.

I.—ENGLAND AND WALES.

THE UNIVERSITIES.

UNIVERSITY OF OXFORD.

THERE are two degrees in Medicine, *B.M.* and *D.M.*, two in Surgery, *B.Ch.* and *M.Ch.*, and diplomas in *Public Health** and *Ophthalmology*. The examinations are open to men and women alike.

Only Graduates in Arts of the University are eligible for the Medical and Surgical degrees. The most convenient course for the B.A. degree for intending graduates in Medicine is to take Responsions, the Preliminary Science Examinations mentioned below, and the Final Honour School of Physiology. To obtain the degrees of B.M. and B.Ch. the following examinations must be passed: 1. Preliminary subjects: Physics and Chemistry, Zoology, and Botany. 2. Professional. (*a*) First Examination: Subjects—Organic Chemistry, unless the candidate has satisfied the examiners in Part I. Chemistry in the Honour School of Natural Science; Human Physiology, unless he has obtained a First or Second Class in Animal Physiology in the Honour School of Natural Science; Human Anatomy. (*b*) Second Examination: Subjects—Medicine, Surgery, Midwifery, Pathology, Forensic Medicine with Hygiene, Materia Medica and Pharmacology. The First and Second Professional examinations are held in June and December. The first B.M. examination may be passed at any time after the Preliminary Scientific examinations. Anatomy and Physiology must be passed at the same time—Organic Chemistry may be taken separately.

At any time after passing *First B.M. Examination*, the candidate can, on producing certificates, present himself for examination in the subjects of Pathology, Forensic Medicine with Hygiene, Materia Medica and Pharmacology; but cannot, unless he is already a registered medical practitioner, enter for examination in Medicine, Surgery and Midwifery until the eighteenth term from his matriculation, nor until a period of at least thirty-three months has elapsed from the date of passing the First B.M. Examination. He must pass in Medicine, Surgery and Midwifery at one and the same time.

Before admission to the Examinations in Pathology and Bacteriology, and Materia Medica and Pharmacology, of the *Second B.M. Examination*, the student must produce certificates of having attended courses of instruction including practical work in Pathology, Bacteriology, Post-mortem Clerking, Pharmacology, and Pharmacy, either in Oxford or in a recognised Medical School. Before admission to the remainder of the second B.M. Examination, he must produce a number of other certificates, including certificates of having acted as Clinical Clerk and Dresser, each for six months in the Wards, of instruction in Midwifery and of attendance on Labours, of instruction in Infectious Diseases and in Ophthalmology, of proficiency in Vaccination and in the administration of Anæsthetics, and of three academic years of hospital practice.

The degree of Bachelor of Surgery (B.Ch.) is granted with that of B.M. after passing the above examinations.

The degree of Doctor of Medicine (D.M.) is granted to Bachelors of Medicine of the University who have entered upon their thirtieth term from Matriculation, and have submitted a dissertation which is approved by the examiners for the B.M. degree whose subjects are dealt with therein and by Professors in the Faculty of Medicine. The degree of Master of Surgery (M.Ch.) is granted after examination to Bachelors of Surgery who have entered upon their twenty-first term, and who are members of the surgical staff of a recognised hospital, or have acted as dresser or house surgeon in such a hospital for a period of six months. The examination, which includes Surgery, Surgical Anatomy and Pathology and Surgical Operations, is held annually in June, after the Second B.M. examination.

Travelling Fellowship, Scholarships, and Prizes.—A Radcliffe Travelling Fellowship is awarded annually after an examination held in February. It is tenable for two years and of the annual value of £800. The examination is in Physiology, Pathology, and Hygiene, and is partly "practical." Candidates must be graduates in Medicine of the University. The holder must travel abroad for the purpose of medical study. Application should be made to the Radcliffe Examiners, Department of Medicine, University Museum. A Schorstein Research Fellowship of the value of £200 a year, tenable for two years, is offered in alternate years. Candidates must be graduates of the University, under 35 years of age, and must hold a registrable medical qualification. Their research must be carried out in one of the Medical Departments at Oxford. A Christopher Welch Scholarship of £100, tenable for four years, is awarded annually after examination. Candidates must be men undergraduate members of the University, who have not exceeded the twelfth term from their matriculation, or been admitted to any degree in the University. They may offer any one of the subjects, Animal Physiology, Botany, Zoology. A George Herbert Hunt Travelling Scholarship of the value of about £100 is awarded every second year to enable a Bachelor of Medicine to undertake three months' study abroad. A Rolleston Memorial Prize is awarded once in two years to members of the Universities of Oxford and Cambridge of not more than ten years' standing for an original research in some Biological subject, including Physiology or Pathology. The Radcliffe Prize, founded by University College (1907), is of the value of £50 and is awarded biennially (alternating with the Rolleston Memorial Prize) for research in some branch of medical science. The Theodore Williams Scholarships, each of the value of £50 a year for two years, are awarded annually in the subjects of Anatomy, Physiology, and Pathology. A Radcliffe Scholarship in Pharmacology, of the value of £50 for one year, is awarded annually by the Master and Fellows of University College. A King's College Hospital Burney Yeo Scholarship of £80 is awarded each year on the nomination of the Regius Professor of Medicine. The Scholarships and Exhibitions in Science which are offered by most Colleges are open to those who intend to pursue Medicine. The value of these scholarships varies, according to the Candidate's need, between £30 and £100 a year; the exhibitions vary in value from £30 to £100 per annum. The number of scholarships and exhibitions in Science offered annually is about forty. There are also Medical Scholarships of the value of £100 a year at University College and at Pembroke College. The Welsh Memorial Prize for Anatomical drawing is awarded annually, and is of the value of about £10.

More detailed information may be obtained from the University Calendar; from the Examination Statutes, 1929; from the Regius Professor of Medicine; from the Professors in the departments of medical science; and from the Dean of the Medical School, Oxford.

UNIVERSITY OF OXFORD: RADCLIFFE INFIRMARY AND COUNTY HOSPITAL.—225 beds. Courses of instruction are given in connexion with the Oxford for Medical Degrees at one or more of the medical institutions or schools recognised by this University for the purpose, one year at least of the four and a half years to have been spent in one or more recognised institutions or schools in the United Kingdom.

---

* Suspended until further notice.

The First Examination for Medical Degrees (Inorganic Chemistry, Physics, including Mechanics, and General Biology) will take place twice in each year, commencing on the Monday following Dec. 7th and on the first Monday in July. It must be passed not less than nine months after matriculation.

The Second Examination for Medical Degrees (Part I.): Organic Chemistry.—This examination will take place twice in each year, commencing on the Thursday following the second Monday in March and on the Thursday following the first Monday in July. No candidate will be admitted to this examination until he has completed the First Examination.

The Second Examination for Medical Degrees (Part II.) takes place twice in every year, commencing on the Tuesday following the third Monday in March and on the Tuesday following the first Monday in July. No candidate shall be admitted to the examination unless he has passed the First Examination for Medical Degrees at least 18 months previously, and has passed Part I. of the Second Examination for Medical Degrees.

The Third or M.B., B.S. Examination.—The M.B., B.S. examination takes place twice in each year, commencing on the second Monday in November and on the first Monday in May. No candidate will be admitted to this examination unless he has completed the Second Examination for Medical Degrees, together with a course of study summarised below, nor within three years from the date of passing the Second Examination, Part II., in Anatomy and Physiology. The course of study comprises introductory course in (1) Clinical Medicine; (2) Clinical Surgery; and (3) Clinical Pathology; (4) Experience as Clinical Clerk; (5) Clinical Medicine; (6) (*a*) Fevers, (*b*) Children's Diseases, (*c*) Venereal Diseases, (*d*) Mental Diseases (at a recognised Asylum), (*e*) Dermatology, (*f*) Vaccination, (*g*) Materia Medica and Pharmacy; (7) Experience as a Surgical Dresser; (8) Clinical Surgery; (9) Ophthalmology; (10) Oto-Rhino-Laryngology; (11) (*a*) Operative Surgery, (*b*) Applied Anatomy, (*c*) Administration of Anæsthetics, (*d*) Dental Surgery, (*e*) Orthopædic Surgery; (*f*) Mechano-therapeutics; (12) Obstetrics and Gynæcology; (13) Lying-in Hospital; (14) The conduct of at least 20 Labours; (15) Antenatal Clinic; (16) Experience as a Clinical Clerk in Gynæcological Work; (17) General Pathology, Morbid Anatomy, Bacteriology, and Chemical Pathology; (18) Work in the Post-Mortem Room; (19) Clinical Laboratory; (20) Forensic Medicine; (21) Hygiene. He must have attended the Medical and Surgical Practice of a recognised hospital for two years, and have held the posts of clinical clerk and surgical dresser for periods of six months each. Candidates will be examined in Medicine, Pathology, Forensic Medicine and Hygiene, Surgery, Obstetrics and Gynæcology. The subjects may be divided into two groups—namely: (1) Medicine, Pathology, Forensic Medicine, and Hygiene; and (2) Surgery, Obstetrics, and Gynæcology. These groups may be taken either separately or together. Bachelors of Medicine who graduated before May, 1904, may obtain the B.S. by passing the Surgical part of the M.B., B.S.

Doctor of Medicine.—The examination for this degree takes place twice in each year, commencing on the second Monday in December and on the first Monday in July. Candidates may present themselves for examination in one of the following branches—namely: (1) Medicine; (2) Pathology; (3) Psychological Medicine; (4) Midwifery and Diseases of Women; (5) State Medicine; and (6) Tropical Medicine. Any candidate for the degree of M.D. (except in branch 5) may transmit to the Registrar a thesis for approval and may be exempted from a part or from the whole of the written examination.

Master of Surgery.—The examination for the degree of Master of Surgery takes place twice in each year: (1) Surgery; (2) Dental Surgery; (3) Ophthalmology; (4) Laryngology, Otology, and Rhinology. A thesis may be submitted as for M.D.

Doctor of Philosophy.—A Degree of Ph.D. has been instituted in non-clinical subjects for External Students in the Faculty of Medicine. Candidates for this degree must hold, in a branch of study akin to that in which they propose to proceed to the Ph.D. Degree, the Degree of M.B., B.S., or B.D.S., or B.Pharm., or B.Sc.

Bachelor of Pharmacy.—The course extends over three years.

Full details of the prescribed curricula can be obtained free on application to the Academic Registrar, or for External Degrees from the External Registrar, University of London, South Kensington, S.W. 7.

MEDICAL SCHOOLS OF THE UNIVERSITY OF LONDON.[1]

ST. BARTHOLOMEW'S HOSPITAL AND COLLEGE.—The hospital contains 757 beds, of which 687 are for patients in the hospital at Smithfield and 70 at the Alexandra Hospital, Swanley. Special departments have been organised for Diseases of Women and Children, the Eye, Ear, Larynx, and Skin, as well as for Orthopædic and Dental Surgery, and for Electrotherapeutics and X Ray work. Whole-time Clinical Units under Professors of Medicine and Surgery have been established. A new Surgical Block of ten wards, with accommodation for 250 patients, and connected with a block of five new operation theatres is nearing completion, and will be ready for use about January 1930.

Ten house physicians and ten house surgeons are appointed annually, are provided with rooms and board, and receive £80 a year as salary. A resident midwifery assistant, an ophthalmic house surgeon, and a house surgeon for diseases of the throat, nose, and ear, and a house surgeon for orthopædic surgery are appointed every six months, and are provided with rooms and board and receive a salary of £80 a year. Three resident administrators of anæsthetics are appointed, the senior for one year at a salary of £150, and two juniors for six months with a salary at the rate of £80 per annum, with board and rooms. An extern midwifery assistant is appointed every three months, and receives a salary of £80 a year. The clinical clerks, the obstetric clerks, the clerks to the medical outpatients, the dressers to the surgical in-patients and to the out-patients, and the dressers in the special departments are chosen from the students. A residential College is attached to the hospital.

There are quarters for the resident staff, casualty, medical, surgical, and special out-patient departments, casualty wards, dispensary, and clinical lecture theatre. There is a chemical laboratory attached to the College as well as a laboratory devoted to instruction in Public Health. A block is devoted to Pathology, and contains the post-mortem room as well as extensive laboratories for bacteriology, clinical pathology, and pathological chemistry. *The Medical College Buildings* include three large lecture theatres, a large dissecting room, laboratories for chemistry, biology, morbid anatomy and histology, and public health, as well as a spacious library (containing 14,500 volumes), a well-appointed museum of anatomy, physiology, comparative anatomy, materia medica, botany, and pathological anatomy. The pathological museum is complete. A new block in Giltspur-street has recently been acquired and has been fitted up as lecture theatres and laboratories for physics, chemical physiology, experimental physiology, histo*logy, and pharmacology.*

---

[1] Of these schools that of the Royal Free Hospital is reserved for women; University College admits men and women to the whole course, the number of women being limited: King's College admits men and women to the intermediate subjects; the remainder admit men only.

Special Classes for the Primary and Final F.R.C.S. are held twice yearly. *Instruction in Preliminary Science* is given to University of London students in chemistry, biology, and physics throughout the year. Facilities for research work are afforded in the Clinical Units and Laboratories of pathological and other departments.

Scholarships given in aid of Medical Study.—For five of the Scholarships and the Exhibition—namely, (*a*), (*b*), two Entrance Scholarships in Science of the respective values of £75 and £100; (*c*) Entrance Scholarship in Arts, £100; (*d*) Jeaffreson Exhibition, £50; and (*e*) Shuter Scholarship, £50—a full or University course at St. Bartholomew's Hospital is required. The awards of (*a*) and (*b*) are made after examination in selections from the subjects of Chemistry, Physics, Zoology, Botany, Physiology, Anatomy, and Pathology; (*c*) and (*d*) are awarded after examination in Mathematics, Latin or Greek or French or German, a second language or Chemistry or Physics; (*e*) is awarded after competitive examination among Cambridge Graduates in Anatomy and Physiology. The more important of the other Scholarships and prizes are as follows:—Four Junior Scholarships—(*f*) No. 1, £30, Anatomy and Physiology; (*g*) No. 2, £20, Anatomy and Physiology; (*h*) No. 3, £25, Chemistry, Physics, and Biology; (*i*) No. 4, £15, Chemistry, Physics, and Biology; (*j*) Senior Scholarship, £50, Anatomy, Physiology, and Chemistry; (*k*) Kirkes Scholarship, £30 and medal, Clinical Medicine; (*l*) and (*m*) two Brackenbury Scholarships, £39 each, one in Medicine and one in Surgery; (*n*) Sir G. Burrows Prize, 10 guineas, Pathology; (*o*) Skynner Prize, 13 guineas, Regional and Morbid Anatomy; (*p*) Matthews Duncan Medal and Prize, £20, Midwifery and Gynæcology; (*q*) Luther Holden Research Scholarship in Surgery, awarded by election, £105; (*r*) Lawrence Research Scholarship and Gold Medal in Pathology, awarded by election, £115; and (*s*) Baly Scholarship in Clinical Medicine, £75, awarded by examination.

The recreation ground of 10 acres is at Winchmore Hill for the use of the members of the Students' Union, which all students are expected to join. The Students' Union contains a large reading and smoking room, a committee and writing room, luncheon and dining hall, and a miniature rifle range.

Information may be obtained on application to the Dean of the Medical College: Dr. T. W. Shore. The Warden of the Residential College is Mr. R. M. Vick.

CHARING CROSS HOSPITAL.—The Hospital, to which the School is attached, contains 300 beds. There are special departments for Mental Diseases, Midwifery, Diseases of Women, of Children, of the Skin, Ear, Throat, Nose, and Teeth, for Orthopædic Cases, X Ray work, and for Electrical Treatment.

In the Medical School Demonstratorships and Assistant Demonstratorships are open to students of the School. Six House Physicians, six House Surgeons, two Obstetric and Gynæcological House Surgeons, and two House Surgeons to the Special Departments are appointed annually. The large proportion of resident appointments to the number of students makes it probable that a student of ordinary ability will be able to obtain one of these appointments.

The following appointments are open to students after they have held resident appointments: Resident Medical Officer, at a salary of £400 per annum; Registrar to the Medical, Surgical, Obstetrical and Ear, Nose, and Throat Departments, at £150 per annum.

By an agreement with the University of London the School sends its Primary and Intermediate Students to receive their lectures and practical work at King's College, which is situated within four minutes' walk.

Final studies are taken in the school and hospital, where systematic lectures, demonstrations, and tutorial classes are arranged to cover all the subjects necessary for qualifying examinations. Departments are also available for other final subjects of Materia Medica and Operative Surgery.

An Institute of Pathology with a whole-time staff of scientific workers and fully equipped laboratories has been established. Students receive their training in Preventive Medicine, Pathology, Bacteriology, and Biochemistry here, and are encouraged to undertake research. Special facilities are available for post-graduate research and study.

The course in Ophthalmology is given in the Royal Westminster Ophthalmic Hospital. Special demonstrations are arranged for Post-graduates.

One Epsom School Scholarship, two Oxford and Cambridge Scholarships, and one Scholarship in Anatomy and Physiology open to students of King's College, are offered for competition each year. In addition there are a number of Exhibitions.

The Museum contains over 4000 specimens, including a notable collection of over 800 gynæcological specimens, the Cuthbert Lockyer Collection.

The social comfort and convenience of students are met by library, reading, and smoking-rooms, refreshment-room, in a Students' Club. The Club, which is under the control of a committee of students, provides needful athletic recreation, and includes also a medical society.

Further information may be obtained on application to the Dean, Dr. F. H. Young.

ST. GEORGE'S HOSPITAL.—This hospital has a service of 430 beds, of which 180 are allotted to surgical, 150 to medical cases, and 100 are at the Convalescent Hospital at Wimbledon. There are all the usual special clinical departments. One ward is set apart for Diseases Peculiar to Women, and there is a Maternity Ward of 11 beds. Children's beds are placed in the women's wards. There are two ophthalmic wards.

Twelve house physicians, 12 house surgeons, and 12 casualty officers are appointed annually. Special attention is directed to the following paid appointments, among others, which are open to students after they have held house office:—Resident Assistant Physician and Resident Assistant Surgeon, at £250 per annum each; Medical Officer to the Atkinson-Morley Convalescent Hospital, at £300 per annum; Medical Registrarship at £200 per annum, Surgical Registrarship at £200; Assistant Curatorship of the Museum at £100; Obstetric Assistantship (Resident) at £50; the post of Resident Anæsthetist at £100; the posts (3) *of Junior Anæsthetists, each at £30.*

Entrance Scholarships and Endowed Prizes of a total value of £700 are awarded annually; a detailed list is placed below. The entire teaching and laboratories are now devoted to purely clinical subjects, and arrangements have been made with the authorities of King's College for students who enter the first, second, or third *year of* the curriculum as students of St. George's to carry out the necessary courses of instruction at that College. Students then complete their course, without payment of any entrance fee, in a school entirely devoted to clinical work.

Scholarships and Prizes.—At this school five entrance scholarships are given, the money value and the subjects of examination being as follows: (*a*) and (*b*) two William Brown Exhibitions, £120 and £80 respectively; (*c*) and (*d*) two University Entrance Scholarships, 90 guineas and £70 respectively; (*e*) Devitt-Pendlebury Scholarship, £50, Anatomy and Physiology, except in the case of (*c*), subject of examination for which is General Pathology.

This year, in addition to these Scholarships, Exhibitions, each of the value of £40 and up to six in number, will be awarded to candidates of approved merit in the Entrance Scholarships Examination. The others are as follows: (*f*) Allingham Scholarship in Surgery for Students qualified not more than two years, £85; (*g*) and (*h*) two Brackenbury Prizes, one in Medicine and one in Surgery, £33 each, open to students of not more than five years' standing; (*i*) H. C. Johnson Memorial Prize, £19, Practical Anatomy; (*j*) Pollock Prize, £23, Physiology, Physiological Chemistry, and Histology; (*k*) Clarke Prize, £5; (*l*) Thompson Medal, £9, Clinical Reports; (*m*) Brodie Prize, £8, Clinical Reports; (*n*) Webb Prize, open to perpetual pupils, £34, Bacteriology; (*o*) Sir Francis Laking Memorial Prize, £65, open to students having registrable qualifications.

The St. George's Hospital Club, with smoking- and luncheon-rooms on the hospital premises and an athletic ground at Wimbledon, is an amalgamation of the Hunterian Society, the *Gazette*, and the Rugby football, cricket, lawn tennis, boxing, rifle, and golf clubs. Students have the advantage of a library of medical and scientific books which is kept up to date.

Further information may be obtained from the Dean of the Medical School, Dr. A. Feiling.

GUY'S HOSPITAL, LONDON BRIDGE, S.E.1.—This hospital contains 646 beds. The whole of the medical school has been rebuilt within recent years. It provides ample accommodation, with modern equipment for all the non-clinical subjects of the medical curriculum.

The following special departments are attached to the hospital: Departments of ophthalmology, laryngology, gynæcology, diseases of children, diseases of the nervous system, dermatology, otology, actinotherapeutics, anæsthetics, dentistry, orthopædics, vaccine, tuberculosis, genito-urinary and venereal diseases, Salomon's Welfare Centre (for Maternity and Children). Dresserships and clerkships in the various special departments are held by students in turn.

There is a Venereal Clinic, in accordance with the Scheme of the Local Government Board and London County Council. Lectures and clinical instruction are given, to which Medical Students and Practitioners are admitted without fee.

House physicians, house surgeons, out-patient officers, assistant house surgeons, obstetric residents, house surgeons in the departments of ophthalmology, laryngology, and genito-urinary diseases, house physicians in the department for diseases of children, and clinical assistants are appointed from among recently qualified students according to merit.

Scholarships.—Six entrance scholarships are awarded annually as follows:—(*a*) one War Memorial scholarship, *of the value of* £200, *to be awarded* alternately in Arts and Science (next award, June or July, 1930 in Science); (*b*) one Open Arts Scholarship of £100 for students under 19 years of age; candidates are required to take English and any two of the following subjects: Latin, Greek, French, German, and Mathematics; (*c*) one Open Junior Science scholarship for students under 20 years, £100; subjects, any three of the following: Inorganic Chemistry, Physics, Biology, and Mathematics; (*d*) a confined Junior Science scholarship of the value of £100 is offered for competition, annually in June or July, to candidates who have attended the Preliminary Science Classes at this School; (*e*) two open Senior Science scholarships: (1) a War Memorial scholarship of the value of £100, awarded annually in September; (2) an open scholarship of the value of £80, awarded annually in September, for students who have completed the curriculum for, or passed the examinations in, Anatomy and Physiology for a medical degree in any University of the British Empire, and who, during the nine months immediately preceding the Scholarship examination, have not entered as students in any Metropolitan Medical School other than Guy's; subjects, any two of the following: Anatomy, Physiology, Organic Chemistry and Pharmacology, General Pathology.

Within the grounds of the hospital are situated the residential college, with accommodation for 35 students, the students' club, with reading, smoking, luncheon, and dining-rooms, a fives court, and swimming bath. The athletic ground and club house is situated at Honor Oak Park, and can be reached in 15 minutes from the hospital.

Further information, together with full particulars of Scholarships, and a booklet entitled "How to Enter the Medical Profession," will be sent post free on application to the Dean of the Medical School, Guy's Hospital, London, S.E. 1.

KING'S COLLEGE HOSPITAL.—The final subjects in the curriculum are taught at the Medical School of King's College Hospital, which is situated at Denmark Hill, S.E. 5.

The hospital has 400 beds, and provision will ultimately be made for 600. There are special departments for Bacteriology, Children, Clinical Pathology, Dermatology, Gynæcology and Obstetrics, Laryngology, Massage, Neurology, Odontology, Ophthalmology, Orthopædics, Otology, Physical Treatment, Psychological Medicine, Radiology, Rhinology, and Urology, each in charge of a specialist and his staff. Clinics are also held in applied pharmacology, cardiology, and medical chemistry.

Appointments.—The appointments open to students are those of clinical assistant to the special departments; medical, surgical, obstetric, and pathological tutorships; resident casualty officers, house physicians and house surgeons; resident anæsthetist; resident radiologist; bacteriologist; clinical pathologist; pathological, medical, surgical, and obstetrical registrarships. Sixteen resident medical and surgical officers are appointed half-yearly.

Scholarships and Registrarships (those in connexion with King's College have already been enumerated).—Scholarships of the total value of £1145 are awarded annually. These include (*a*) Medical Entrance Scholarships—Science, £50; Anatomy and Physiology, £50; Pathology, £75; (*b*) two Burney Yeo Entrance Scholarships, £80 each, open to students of Oxford and Cambridge on the recommendation of the Regius Professors; (*c*) two Raymond Gooch Scholarships, £120 each, open to students of British Universities on certain conditions; (*d*) an Epsom College Scholarship, value £50 at least, offered annually to a student of Epsom College who has taken the first part of the courses for Medical Degrees at the Universities of Oxford, Cambridge, or London; (*e*) two Seaman Scholarships, each £50 a year for a period not exceeding five years, restricted to the sons of clergymen of the Church of England; (*f*) Senior Scholarship (Clinical Studies), £40. The holders of the Warneford and Sambrooke Scholarships awarded by King's College are required to take the subjects of the preliminary and intermediate examinations at King's College, and the final subjects at King's College Hospital. Three Sambrooke Registrarships, open to matriculated students who have filled certain appointments in hospital.

Prizes.—Tanner Prize, £10, Obstetrics and Diseases of Women; Todd Prizes, First £8 and medal, second £4, for Clinical Medicine; Burridge Prize, £4 4*s.*, Forensic Medicine; Jocelyn Almond Prize, £5 5*s.*, Diseases of Children; Wallis Prize, £10, History of Dentistry; 13 Class Prizes, £3 each.

The King's College Hospital Clubs and Societies Union consists of the Listerian and Musical Societies, the Students' Common Rooms, and the various athletic and sports clubs. The athletic ground, over six acres in extent, is on Dog Kennel Hill, about ten minutes' walk from the hospital. There are also Tennis Courts in the grounds of the Hospital and of "The Platanes"—a hall of residence for students belonging to the hospital.

The Calendar of the School will be sent on application to either of the following: Dr. H. Willoughby Lyle, Dean; Mr. S. C. Ranner, Secretary of the Medical School.

LONDON HOSPITAL.—The hospital, with its Medical College and Dental School, is situated in Mile End-road, and contains 839 beds. There are special departments for diseases of the Eye, Ear, Nose and Throat, Skin, Teeth, and Pediatric, Orthopædic, Venereal, Radiological, Electro- and Physico-therapeutical and Inoculation Departments.

To each medical and surgical firm throughout the hospital there is attached a First Assistant, who is responsible for instructing the clerks or dressers of the firm in elementary medicine and surgery, and who assists the honorary members of the firm in the preparation of their demonstrations. In the department of Obstetrics and Gynæcology there are two assistants and two resident accoucheurs. Special courses of lectures and demonstrations are arranged in Medicine and Surgery and their ancillary subjects. Opportunities for research are provided under the supervision of the staff.

Owing to the large number of patients more appointments are open to students before and after qualification than at any other hospital. Holders of resident appointments have free board. Special classes are held for the examinations of the University of London, for the Fellowship of the Royal College of Surgeons, for the Membership of the Royal College of Physicians, and for other higher examinations. Special entries for medical and surgical practice can be made.

A Clinical Unit in Medicine, under the charge of a whole-time director, provides for the more elaborate methods of diagnosis and treatment, and takes a leading part in the initiation and coördination of medical research. The director has an assistant director, two assistants, and two house physicians.

Scholarships and Prizes.—The following is a list of the Scholarships and Prizes:—Entrance Scholarships: Price Scholarship £100, and one Scholarship of £50, subjects of First Medical Examination at the University of London; Epsom College Scholarship, free education, subjects of First Medical Examination as above; Price Scholarship, open to students of Oxford and Cambridge Universities, (1) £100, Pathology; (2) £100, Human Anatomy and Physiology; two Open Scholarships, each of the value of £100, subjects, Human Morphology and Embryology, Physiology and Pharmacology, Biochemistry, Pathology, Bacteriology and Morbid Anatomy. Prizes: Buxton Prize, £40, subjects of Anatomy and Physiology; three Prizes for Clinical Work, £20 each, Medicine, Surgery, and Obstetrics and Gynæcology; Sutton Prize, £20, Pathology; Duckworth Nelson Prize, biennial, £10, Practical Medicine and Surgery; Letheby Prizes (2), £25, Chemistry and Chemical Pathology; four Dressers' Prizes, amounting to £20, zeal, efficiency, and knowledge of Elementary Clinical Surgery; Hutchinson Prize, triennial, £60, Clinical Surgery; Treves Prize, £15, Clinical Surgery; two Practical Anatomy Prizes, £6 and £4 respectively; Andrew Clark Prize, £14, Clinical Medicine and Pathology; T. A. M. Ross (Prox. Acc.) Prize, £10 10*s*., Clinical Medicine and Pathology; James Anderson Prizes (4), £20, Elementary Clinical Medicine; Arnold Thompson Prize, £15, Diseases of Children; and Liddle Prize, triennial, £120.

Medical Research Funds.—Funds to the value of over £113,000 permit of financial assistance being given to students and graduates engaged in Medical Research.

A laboratory for the manufacture of certain preparations of Radium has recently been endowed.

Two Residential Hostels are provided for students, and a hostel for 40 resident medical officers. The Union Athletic Ground, 13 acres, is within easy reach of the hospital.

Dean: Prof. William Wright.

ST. MARY'S HOSPITAL.—The Hospital and Medical School have on one side a poor district of 500,000 persons, and on the other side the residential districts of Kensington and Bayswater. The hospital contains 350 beds, and recent structural additions have added two new operating theatres. By a scheme of affiliation, for teaching purposes, of certain neighbouring hospitals, the teaching facilities extend over 1000 beds. The Medical School provides complete courses of instruction, and students can join at once on passing a Preliminary Examination in Arts. Terms begin in October, January, and April.

Clinical Units in Medicine and Surgery were established in 1920. Lying-in beds have recently been added, and, in addition to this, arrangements have been made by which all students take out a short course of instruction in Practical Midwifery at Queen Charlotte's Hospital without additional fee.

Students specially interested in Pathology and Bacteriology have singular advantages at St. Mary's. The institute comprises seven special departments, the whole being under the personal direction of Sir Almroth Wright. Certain Research Scholarships of *£200 each are awarded annually to students working* in the departments of the institute; and research beds have been instituted. Clerkships in Pathology, Bacteriology, and Chemical Pathology, lasting for a period of three months, are open to students of the fifth year, and enable them to carry out the Pathological and Bacteriological investigations of the wards, and learn the necessary technique under supervision. Seventy-two of these posts are available annually. Numerous appointments are open to newly qualified members of the Medical School, including ten salaried posts with salaries varying *from £200 to £750 per annum. A special Post*-graduate course is held during the first week-end in October, and is open to all General Practitioners and other qualified men without fee.

Entrance Scholarships.—Two Entrance Scholarships of the value of £210 each are awarded annually, by nomination in July, the Geraldine Harmsworth Scholarship, £200, and one or more University Scholarships of £200 are awarded in July.

The Athletic ground (10 acres) is situated at Wembley and can be reached in 20 minutes by a constant service of trains. A large pavilion has *recently been added.*

For further information apply to the Dean of the Medical School.

MIDDLESEX HOSPITAL.—The hospital contains over 300 beds, with special wards for Cancer, Maternity and Gynæcological and Ophthalmological cases, and for Diseases of Children. Other special departments include those for Diseases of the Eye, Ear, Nose and Throat, and Skin; Nervous diseases, Orthopædic cases, Diseases of the Rectum and Venereal Diseases. There is also an Electrotherapeutic department. The Cancer Hospital, containing *92 beds and Special Investigation* Laboratories, offers unrivalled opportunities for the study of Cancer, both in its clinical and pathological aspects. In the Electrotherapeutic Department, students obtain instruction in the Treatment of Lupus and Cancer by the X ray method of treatment.

All appointments are made without fee of any kind, and the following are appointed at intervals annually: six house physicians, eight house surgeons, two obstetric and gynæcological house surgeons, two casualty medical officers, two casualty surgical officers, one senior resident anæsthetist, two junior resident anæsthetists, *and four resident officers to the special* departments. Ten registrars are appointed annually. Non-resident qualified clinical assistants are appointed to assist in the various out-patient departments. Clinical clerks and surgical dressers are also appointed in every department.

The Medical School, which includes the Bland-Sutton Institute of Pathology, the Courtauld Institute of Biochemistry, and the Barnato-Joel Laboratories, is fully equipped for the theoretical and practical teaching of all the subjects of the medical curriculum, for the Diplomas in Public Health, and the University of Cambridge Diploma in Radiology, for which two courses are held yearly. Ample laboratory and class-room accommodation is provided. The teaching staff includes 6 Professors, 32 recognised Teachers, 10 Demonstrators, 4 Tutors. The Bland-Sutton Institute of Pathology and the Courtauld Institute of Biochemistry are completely equipped for routine hospital investigations, teaching and research work, and contains large pathological, bacteriological, and clinical laboratories, also smaller laboratories for individual research work. A well-equipped Anatomical and Pathological Museum and Reference Library offer every facility.

Other features of interest are: the course in Medical Radiology and Electrology, under the direction of the "Joel" Professor of Physics; D.P.H. course, under the direction of Dr. Charles Porter, M.O.H., St. Marylebone, Prof. J. McIntosh, and Prof. W. B. Tuck. A primary F.R.C.S. course is held twice yearly, and also special classes to prepare students for the Intermediate Examinations of the Universities.

Scholarships and Prizes.—Two Entrance Scholarships, value £100 each, and two University Scholarships, value £90 and £60, are awarded annually in September. The successful candidates are required to become general students of the school. A Freer Lucas Scholarship is awarded annually on the nomination of the Headmaster of Epsom College. There are also two Broderip Scholarships, value £60 and £40 respectively; the Lyell Gold Medal and Scholarship, value £55 5*s.*; the John Murray Medal and Scholarship, value £25 (awarded every third year); the Freeman Scholarship, value £30; the Hetley Clinical Prize, value £25; the Leopold Hudson Prize, value 11 guineas; and the Second Year's Exhibition, value 10 guineas. There are also numerous class prizes.

The Students' Amalgamated Clubs include the following: Medical Society, Common Room Society, Musical Society, cricket, football, rowing, chess, lawn tennis, hockey, sailing, and fencing. There are a restaurant and a gymnasium in the school buildings, and large athletic grounds at N. Wembley, with new pavilion.

For further particulars apply to the Dean or the Secretary of the Medical School.

ST. THOMAS'S HOSPITAL.—This Hospital contains 644 beds. There are special departments for the treatment of women, children, diseases of the eye, ear, nose and throat, skin, teeth, and for orthopædics. Nervous and mental diseases are treated in special departments. An electrocardiograph has been installed for the investigation of diseases of the heart. The Tuberculosis Department forms a part of the Lambeth scheme for treatment of patients and for instruction. The Venereal Department has been established as part of the London County Council scheme. Departments for Radiology, Electrotherapy, Phototherapy, Massage and Remedial Physical Exercises are also special features. A speech clinic has been inaugurated in connexion with the Children's Department. Exceptional facilities are offered in the hospital laboratories for the study of General Pathology, Clinical Pathology, Chemical Pathology, and of Treatment by Serums and Vaccines. Surgical operations take place in the main theatres every day, except Saturdays, at 2 P.M. Clinical teaching in the wards, out-patients' and special departments, is available every day of the week. Clinical lectures are delivered every Wednesday during the sessions. A Clinical Unit in Medicine has been established.

All appointments in the hospital are open to students without extra fee. Clinical clerks and dressers for in- and out-patients are selected from students who have completed their third years' work. Every student acts as clerk in the post-mortem room and in one of the pathological laboratories, takes his turn on maternity duty under proper supervision in the maternity ward and district, thus obviating any necessity for seeking instruction elsewhere. Students are instructed in the administration of anæsthetics by the hospital anæsthetists.

The arrangements are made to meet the requirements of all the Examining Bodies. Special classes are held for the examinations at the University of London and for the First and Final Fellowship Examinations of the Royal College of Surgeons of England. Tutorial classes in all subjects precede the various examinations. The hospital is easily accessible from all parts.

Appointments.—A Resident Assistant Physician and a Resident Assistant Surgeon, salary £225 each per annum, and a Resident Anæsthetist, salary £200 per annum, are appointed annually. Two Hospital Registrars, Medical and Surgical, at an annual salary of £250 each are appointed yearly. The tenure of these offices may be renewed for a term not exceeding two years. A Pathological Registrar to the Department of Obstetrics and Gynæcology (at an annual salary of £250), an Ophthalmic Registrar (at an annual salary of £200), and an Orthopædic Registrar (unpaid) are appointed yearly. Two Senior Resident Casualty Officers (Medical and Surgical) are appointed yearly. *Eight Resident Casualty Officers and Anæsthetists* are appointed every six months. Seven House Physicians (including two Obstetric House Physicians, and one House Physician to the Department of Diseases of Children), nine House Surgeons (including two Ophthalmic House Surgeons, one Orthopædic House Surgeon, and two House Surgeons to the Ear, Nose and Throat Department) are appointed every six months. Clinical Assistants in the Special Departments are appointed every three months, and hold office for six months if recommended for re-election. There are three Assistants in the Department of Pathology; the Senior receives £600 a year, and the two Juniors £450 each.

Scholarships and Prizes.—At this school there are five Entrance Scholarships—namely, two in Arts, equivalent to the tuition fees for the first year of study; two in Natural Science, of the value of £150 and £60 respectively; and the University Scholarship of £100 in any two of the following: Anatomy, Physiology, Pathology, Chemistry. The value of all entrance scholarships must be taken out in tuition fees. The money value and subjects of examination of the remainder are as follows: (*a*) William Tite Scholarship for second-year students, £25; (*b*) and (*c*) Musgrove Scholarship or (alternately) Peacock Scholarship, each for third-year students and tenable for two years, £35 each; (*d*) Mead Medal, Medicine, Pathology and Hygiene; (*e*) Wainwright Prize, Medicine; (*f*) Toller Prize, Medicine; (*g*) Cheselden Medal, Surgery and Anatomy; (*h*) Clutton Memorial Medal in Clinical Surgery, biennial; (*i*) Beaney Scholarship, £50, biennially, Surgery and Surgical Pathology; (*j*) Solly Medal and Prize, biennial, Reports of Cases; (*k*) Sutton Sams Prize, biennial, Report of Cases; (*l*) Bristowe Medal, Pathology and Morbid Anatomy; (*m*) Hadden Prize, Pathology and Morbid Anatomy; (*n*) Grainger Testimonial Prize, £31 10*s.*, Anatomy and Physiology; (*o*) Louis Jenner Research Scholarship, tenable for two years, £60 annually, Pathology; (*p*) School Council Research Scholarship, £250 per annum, tenable for two years; (*q*) John and Temple Research Fellowship, tenable for two years, £450, Children.

St. Thomas's House, the New Students' Club recently opened, comprises spacious dining-, smoking-, and reading-rooms, and accommodation for some 60 resident students. There is no occasion for students to leave the hospital premises during working hours.

Further information may be obtained from the Medical Secretary of the School, St. Thomas's Hospital.

UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL.—The final subjects in the curriculum are taught at the Medical School of the hospital, which has 526 beds, including 74 in the new obstetric hospital. The course of instruction is suitable for the examinations at the

Universities of Oxford, Cambridge, Durham, and other British Universities, and for the medical education required by the Examining Board in England and the Society of Apothecaries. Clinical Units in Medicine, Surgery, and Obstetrics and Gynæcology are now in operation. The whole-time Directors of the Units are concerned with the organisation of the teaching generally, but the honorary staff are responsible for the largest share of the teaching in the wards and Out-patient Department of the hospital. The department of otology, rhinology, and laryngology (the Royal Ear Hospital) has been provided with a separate building in Hunter-street, adjacent to the obstetric hospital. It contains 30 beds, including eight private wards for patients of limited means. The hospital is equipped with all modern appliances for investigation. The new buildings of the Obstetric Hospital of 74 beds (rendered possible by the Rockefeller Benefaction), the new Residents' House (with accommodation for *80 residents and students), the extension to the Nurses'* Home, and new research laboratories for the Medical School are now finished and in full occupation. Twelve women students are admitted annually.

Those who are desirous of carrying out original research in Pathology, including Morbid Anatomy, Bacteriology, Experimental Pathology, and Chemical Pathology, are admitted to work in the laboratories of the school by the Professor of Pathology, and under certain conditions can receive grants from the Charles Graham Medical Research Fund. A special course of instruction is given in conjunction with University College for preparation for the examinations for Diplomas in Public Health of the various universities and examining bodies. In the Dental School in Great Portland-street, formerly known as the National Dental Hospital, there is afforded the opportunity for attending lectures and practical instruction in diseases of the mouth and teeth.

Appointments.—Clerkships and dresserships to the physicians, surgeons, anæsthetist, and pathologist are allotted amongst the students of the hospital. Maternity students are appointed each month and reside in the Students' House connected with the Medical School and Hospital. Sixteen house physicians, ten house surgeons, ten obstetric assistants, four house surgeons to the Royal Ear Hospital (of the total number of resident officers not more than three may be held by women students at any one time) are selected annually by examination from among the senior students who have a medical qualification. All house officers reside free in the hospital. In addition to these posts there are certain special appointments which are vacant from time to time and are filled by senior students of the hospital: Resident Medical Officer, Surgical Registrar, Medical Registrar, Obstetric Registrar, Harker-Smith Cancer Registrar, Ophthalmic Registrar, Registrar to the Royal Ear Hospital, Casualty Medical Officer and a Casualty Surgical Officer, Assistants in Ear and Throat, Skin and Venereal Diseases Departments, and House Anæsthetist.

Assistants to the Medical, Surgical, and Obstetric Units.—These salaried appointments, that have come into existence recently at the same time as the creation of the whole-time Chairs in Medicine, Surgery, and Obstetrics, are of great value to senior students who may desire to remain at Hospital after holding the ordinary resident appointments. They enable a man to continue clinical work and also to devote time to laboratory or other research, so as to fit himself for higher posts in the profession. The salaries range from £250 up to £800 a year, resident quarters being provided only for the chief assistant to the Obstetric Unit. The total number of such Assistantships varies from time to time, being generally about 12, and an aggregate sum of about £5000 annually is available for their salaries.

Scholarships and Prizes (those in connexion with University College have already been enumerated).—At this School the first two Scholarships (*a*) and (*b*) entitle the holder to a complete course at University College and University College Hospital Medical School; the second two (*c*) and (*d*) entitle to a final course at the Medical School. The money value and subjects of examination are as follows:—(*a*) Entrance Scholarship, Bucknill, 135 guineas, Chemistry, Physics, Botany, and Zoology; (*b*) Epsom Free Medical Scholarship, subjects of Preliminary Scientific Examination and Nomination by Epsom College; (*c*) and (*d*) two Goldsmid Entrance Exhibitions 112 guineas each, Anatomy or Physiology, or General Pathology; (*e*) Graham Scholarship in Pathology, £300 per annum for two years, awarded by the Senate of the University of London; (*f*) Atkinson Morley Scholarship, tenable for three years, £45 per annum, Surgery; (*g*) Atchison Scholarship, tenable for two years, £55 per annum, General Proficiency in Medical Studies; (*h*) Magrath Clinical Scholarship, about £150, Clinical Cases; (*i*) Percival Alleyn Scholarship, about £75, Surgery; (*j*) Filliter Exhibition, £30, Pathology; (*k*) Erichsen Prize, £10 10s., Practical Surgery; (*l*) two Senior and two Junior Fellowes Clinical Medals for Clinical Medicine; (*m*) two Liston Gold Medals for Clinical Surgery; (*n*) Alexander Bruce Gold Medal for Pathology and Surgery; and (*o*) Tuke Silver and Bronze Medals for Pathology. (*p*) Radcliffe Crocker Travelling Scholarship for Dermatology. (*q*) Leslie Pearce Gould Travelling Scholarship for Surgery.

The *Museum of Pathological Anatomy* is open for study daily, and microscopic sections of most of the specimens have been prepared and are available for the use of students on application to the Curator. The Anatomical Museum of the University of London, University College, is open to all students of University College Hospital and Medical School on the recommendation of the School Committee. The Medical Library, open daily to every student of the School, contains about 20,000 works on medical subjects, including all the current text-books and works of reference required for study or research.

The Medical Society of University College Hospital Medical School exists for the dual purpose (1) of promoting the study of medical and surgical science, and (2) of promoting social intercourse among its members. All male students of the Medical School are required to become members. Meetings are held once a fortnight for the purpose of discussing subjects connected with the study of medicine. In its social aspect the society includes various athletic clubs and superintends the gymnasium and squash racquet court in the Medical School, and the Athletic Ground at Perivale.

University College Hall, Ealing, is recognised by the authorities as a residential hostel. The Students' House in University-street contains large and comfortable rooms. The Maternity Students occupy them on payment of a moderate charge.

Full information can be obtained from the Dean of the School.

WESTMINSTER HOSPITAL.—The Hospital contains 218 beds, and has attached to it a Radium Clinic with 23 beds. There are separate departments for diseases of the eye, skin, teeth, ear, nose and throat, for orthopædic practice, for diseases of women, for diseases of children, for radiography, for venereal disease, and for massage, electrical and light treatment. The anatomical, pathological, and materia medica museums are open to all students of the School.

The entire teaching of the Hospital is devoted to the subjects of the Final Examinations. Arrangements are made for the tuition required for Preliminary and Intermediate subjects.

Appointments: Paid appointments as Medical, Surgical, and Obstetric Registrars, Casualty Officers, House Physicians, House Surgeons, Anæsthetist, &c., are available for students when they have passed their examinations.

Research: There are excellent opportunities for Research work in the recently endowed John Burford Carlill Laboratories. Grants to assist Research workers are made annually from the John Burford Carlill Endowment.

Fees: Annual fee, £40. An entrance fee of 10 guineas includes membership of the Sports Union Club with its various branches—i.e., football, cricket, tennis, boxing, and Guthrie Society. The Athletic Grounds are situated in Tooting and are reached in 20 minutes from the hospital.

Scholarships and Prizes.—The following Entrance Scholarships are offered for competition: Winter Session: Two Scholarships in Anatomy and Physiology, £75 each. Summer Session: Two Scholarships in Anatomy and Physiology, £75 each. A certain number of Scholarships have been allotted to Universities of England, Wales, and the Colonies, and to Public Schools. These Scholarships are awarded entirely on the nomination of the principal of the university or school. During the period of study the following prizes may be competed for: Sturges Prize in Clinical Medicine, about £6, Reports on Cases; Chadwick Clinical Surgery Prize, £5, Reports on Cases; Chadwick Prize, £21 in books or instruments—Medicine and Surgery, including Pathology and Applied Anatomy and Physiology; Frederic Bird Medal and Prize, open to Fourth-year Students, £14 in medal and books or instruments—Midwifery, Diseases of Women, Medicine, Pathology, Forensic Medicine and Bacteriology, and Public Health and Toxicology; Abrahams Prize in Clinical Pathology, 5 guineas, a Paper and Tests in Practical Work; Alfred Hughes Memorial Prize, open to Second-year Students, about £5 in books or instruments—Anatomy; Huxley Memorial Prize, 3 guineas in books or cash, open to Second-year Students—Physiology; Carter Gold Medal and Prize for Botany, open to Students of not more than three years' attendance, gold medal and books of the joint value of £15; Jelf Medal awarded to Third-year Students; Second-year Scholarship £20, Elementary Anatomy, Physiology, Histology, and Organic Chemistry; Daniell Scholarship, £40, Chemistry; Rabbeth Scholarships open to First-year Students, one of £30 and one of £15; Class Examinations in the Preliminary Scientific Course.

Inquiries should be addressed to the Dean of the Medical School.

ROYAL FREE HOSPITAL, LONDON: SCHOOL OF MEDICINE FOR WOMEN.—The Royal Free Hospital contains 268 beds. The Hospital also has large Casualty and Out-patient Departments. A Children's Department, including 18 cots, an Orthopædic Department, and a Light Department have recently been added to the Hospital. Maternity Districts are attached to the Unit operating in the Gray's Inn-road and Essex-road areas. Students also attend the in-patient and out-patient practice of the Elizabeth Garrett Anderson Hospital, Cancer Hospital, Hospital for Sick Children, Great Ormond-street, National Hospital, Queen Square, South London Hospital, and Royal London Ophthalmic Hospital.

A Clinical Unit in Obstetrics has been established controlling 68 beds. Courses are arranged for the Primary Fellowship Examination of the College of Surgeons. The Eastman Dental Clinic, for which Mr. George Eastman, of Rochester, N.Y., has provided the building fund, is in course of erection and will provide a Dental School for women; at present the course for dental students is in conjunction with the Royal London Dental Hospital, Leicester-square.

The School buildings have been entirely rebuilt in recent years, and there are spacious, well-equipped laboratories, which afford every facility for efficiency of teaching and practical work in all departments.

There are residential chambers in the neighbourhood and the Warden can be consulted on the subject.

Students after qualification can hold the posts of house physicians, house surgeons, obstetric assistants, clinical assistants, assistant anæsthetist, medical, gynæcological, and surgical registrars, and assistant pathologist; and at the Medical School the posts of demonstrators in the departments of Anatomy, Physiology, Pharmacology, Biology, Chemistry, and Physics.

Scholarships and Prizes. Among the larger of these awards are the following:—(*a*) Isabel Thorne Scholarship, £30. (*b*) St. Dunstan's Medical Exhibition, £60 a year, tenable for three or five years. (*c*) Mrs. George M. Smith Scholarship, £50 a year, tenable for three or five years. (*d*) Bostock Scholarship, tenable for two or four years, £90 (*e*) Mabel Sharman-Crawford Scholarship, tenable for four years, £20 a year. (*f*) Sir Owen Roberts Scholarship, £75 a year for four years. (*g*) Mabel Webb Research Scholarship, tenable for one year and renewable, £30, Physiology, Chemistry, or Pathology. (*h*) Fanny Butler Scholarship, tenable for four years; next award in July, 1931, £16. (*i*) John Byron Bursary, tenable for two years, for students already in the School requiring assistance for the prosecution of their medical studies; application to the Secretary by March 31st next, £20. (*k*) Helen Prideaux Prize and Julia Ann H. Cock Prize, to be spent in assisting the newly qualified holder to further study, £60 each. (*l*) Dr. Edith Pechey Phipson Post-graduate Scholarship of the value of £100, open to all medical women, preferably coming from India, or going to work in India, (*m*) Sarah Holborn Scholarship, value £20 a year for three or five years, awarded every alternate year; next award in 1931. (*n*) Dr. Margaret Todd Scholarship, tenable for four years, £37 10*s*. a year, awarded in alternate years; next award in July, 1931. (*o*) Lieutenant Edmund Lewis and Lieutenant Alan Lewis Memorial Scholarship, tenable for four years, awarded every four years; next award in July, 1932. (*p*) Alfred Langton Scholarships, tenable two years, one awarded annually, £50 a year. (*q*) School Jubilee Bursary, tenable for three years, £50 a year. (*r*) Flora Murray Bursary, awarded every year to a fifth-year student, £50. The Dorothy Chick Gift, £20, is awarded annually for efficiency in Practical Midwifery.

The Students' Union arranges the social, athletic, and other clubs and societies. The School sports ground, consisting of 7½ acres of freehold land, is situated at Sudbury (easily reached from Euston Station).

Inquiries may be addressed to the Warden and Secretary of the Medical School, 8, Hunter-street, London, W.C.

UNIVERSITY OF DURHAM.

The University of Durham grants degrees of Bachelor of Medicine, Bachelor of Surgery, Doctor of Medicine, Master of Surgery, Doctor of Surgery, Bachelor of Hygiene, Doctor of Hygiene, Bachelor of Dental Surgery and Master of Dental Surgery, the Diploma in Public Health, Diploma in Psychiatry, and a Licence in Dental Surgery.

For the degrees of *Bachelor of Medicine* and *Bachelor of Surgery* there are four professional examinations. The subjects of the First Examination are—Elementary Biology and Organic Chemistry. The subjects of the Second Examination are—Anatomy and Physiology. The subjects of the Third Examination are—Pathology and Bacteriology, Materia Medica, Pharmacology and Pharmacy, Medical Jurisprudence, and Public Health. The subjects of the Fourth Examination are—Medicine, Clinical Medicine, Therapeutics, Surgery, Clinical Surgery, Operative Surgery, Midwifery and Gynæcology, Psychological Medicine, Diseases of the Skin, of the Throat, Nose, and Ear, and of Children, and Ophthalmology. It is required that at least one of the five years of professional education shall be spent at the University of Durham College of Medicine, Newcastle-upon-Tyne.

For the degrees of *Doctor of Medicine* and *Master of Surgery* a candidate must not be less than 24 years of age. He must also have obtained the degrees of

Bachelor of Medicine and Surgery of the University of Durham, and must have been engaged for at least two years subsequently to the date of admission to these degrees in research work, or in attendance on the practice of a recognised hospital, or in the naval or military services, or in medical or surgical practice. The candidate for the M.D. degree may present an essay or undergo a special examination in the subjects of Medical Anatomy, Medical Pathology, and the Principles and Practice of Medicine. The subjects of examination for the M.S. are:—Principles and Practice of Surgery, Surgical Pathology, Surgical Anatomy, Surgical Operations, Clinical Surgery.

Doctor of Medicine (without residence).—The University of Durham has instituted a special examination whereby the degree of Doctor of Medicine may be obtained without residence. Candidates must not be under 40 years of age and must have been in active practice for 15 years as registered medical practitioners. They must also produce certificates of moral character from three registered members of the medical profession. The fee is 50 guineas (including the degree fee), of which 20 guineas is retained if the candidate fails to satisfy the examiners.

Doctor of Surgery.—The University of Durham grants the Degree of Doctor of Surgery. Candidates for this degree must be registered medical practitioners, and not less than 25 years of age. They must devote three years, subsequently to obtaining a registrable qualification, to the study of Surgery and ancillary subjects. One at least of the three years must be spent in the University. The candidate must submit to the Professor of Surgery the course of study he proposes to follow, and this course must be approved by the Board of the Faculty of Medicine. One year shall be devoted mainly to work in the departments of Anatomy, Physiology, Pathology, and Bacteriology, and the candidate must submit evidence of having so worked. Not less than six months of another year must be spent as resident surgeon in a recognised teaching hospital, and the rest of the year in the study of surgery in a recognised medical centre. Not less than six months of one of the three years must be spent in surgical study abroad.

Candidates for any of the above degrees, diplomas, or licence must give at least 28 days' notice to the Secretary of Examinations, University of Durham College of Medicine, Newcastle-upon-Tyne. In the case of the M.D. (essay) examination candidates must send in their essays before April 1st.

Scholarships and Prizes.—The following are awarded:—University of Durham Entrance Scholarship, £25 a year for four years; Pears' Entrance Scholarship, £40 a year for three years (awarded every third year); Heath Entrance Scholarship (from Kepier Grammar School), £60 (renewable); Province of Durham Masonic (Entrance) Scholarship, £60 (renewable); Heath Scholarship for Surgery, £200, available every second year; Rutherford Morison Surgical Scholarship, £180, available every third year.

The following Scholarships are tenable for one year, namely:—Tulloch Scholarship for Elementary Biology and Organic Chemistry, £20; Dickinson Scholarship for Medicine, Surgery, Midwifery, and Pathology; Gold Medal and £20; Charlton Scholarship for Medicine, £25; Gibb Scholarship for Pathology, £28; Luke Armstrong Scholarship for Comparative Pathology, £25; Stephen Scott Scholarship for Surgery, £40; Philipson Scholarships for highest marks in Final M.B., B.S. Examinations, two of £48 each; Goyder Memorial Scholarship for Clinical Medicine and Clinical Surgery, interest on £325; Gibson Prize for Midwifery and Diseases of Women and Children, £10; Turnbull Prize and Silver Medal for Surface Anatomy; and Outterson Wood Prize for Psychological Medicine, £10; Sewell Memorial Prize and Silver Medal for Clinical Pathology.

For further information apply to the Dean of the College.

COLLEGE OF MEDICINE, Newcastle-upon-Tyne.—Hospital practice is carried out at the Royal Victoria Infirmary, a general hospital containing more than 550 beds, and there are facilities for the study of the various special subjects.

Practical midwifery can be studied at the Princess Mary Maternity Hospital, which contains 90 beds, with an annual indoor and outdoor attendance on 3000 cases.

The bacteriological laboratory is adjacent to Armstrong College.

A *Students' Union* has been erected and furnished at a cost of over £54,000, and is now in daily use. Special accommodation has been provided for women students.

NEWCASTLE-UPON-TYNE ROYAL VICTORIA INFIRMARY.—The Infirmary has 572 beds. Clinical Lectures are delivered by the Physicians and Surgeons weekly and ward demonstrations are given daily. Tutorial classes are held by specially appointed *Medical Tutors, Assistant Surgeons and Senior Assistant* in the Gynæcological Department, and demonstrations are given in the several out-patient departments daily. Pathological demonstrations are given by the Pathologist daily or as opportunity occurs, and in the new buildings nothing has been spared in perfecting scientific equipment. In addition to medical and surgical in-patient and out-patient departments the following special departments are fully equipped for teaching students: Ophthalmic, Throat, Nose, and Ear, Skin, and Venereal Disease, Gynæcological, and Electrical. The hospital building contains the following laboratories: 1. Special Pathological Laboratory, attached to the post-mortem rooms. 2. Bacteriological Laboratory in which all clinical bacteriological investigations are carried out with a view to treatment by vaccines and serums. 3. There is in addition a Clinical Laboratory attached to each ward and to the out-patient department. There are five operating theatres in use in the hospital. The winter session *of 1929 opens on Oct. 2nd and the summer session* of 1930 on April 7th.

Applications for detailed information should be made to the Sub-Dean, Dr. Horsley Drummond, at the hospital.

Practical Midwifery is studied at the Princess Mary Maternity Hospital, a new building, excellently equipped, with 90 beds. Instruction is given in Psychological Medicine at the City of Newcastle Mental Hospital. A special course of instruction is given in the City Hospital for Infectious Diseases by the City Officer of Health.

Post-graduate Instruction.—1. General courses in Clinical Medicine, Surgery, and Pathology at the Royal Victoria Infirmary, meeting once weekly for ten weeks. One course will be held from October to December and one from April to June. 2. Special courses of clinical instruction, meeting once weekly for ten weeks, in the following subjects: Gynæcology; Diseases of the Eye; Diseases of the Throat, Nose, and Ear; Diseases of the Skin; Venereal Diseases; *Neurology*; Diseases of Children; Electrotherapeutics and Radiology; special courses in Midwifery will be held at the Princess Mary Maternity Hospital. 3. An intensive course of 14 days' duration in the early part of the Summer Vacation. 4. In addition to the regular post-graduate courses practitioners may attend the ordinary medical and surgical practice of the Royal Victoria Infirmary, and also at the Princess Mary Maternity Hospital, for specified periods.

UNIVERSITY OF BIRMINGHAM.

The University of Birmingham grants the degrees of M.B., Ch.B., M.D., Ch.M., and Ph.D. (for Research Study), and also a degree and a diploma in Public Health. The course for the Bachelors' degrees, including the subjects of Physics, Chemistry and Biology, extends over six years. The Senate has power of recognising attendance at another University as part of the attendance qualifying for these degrees and of recognising examinations passed at such other Universities as exempting from the examinations in Physics, Chemistry, Biology, and Organic Chemistry; but at least three years must be spent in attendance upon classes in the University. The final year may be spent at any other medical school recognised by the University.

Degrees of Bachelor of Medicine and Bachelor of Surgery.—The student must have passed the Matriculation Examination of the Joint Board or an examination accepted in lieu thereof. Before commencing the study of Anatomy and Physiology examinations in Chemistry and Physics and Biology must be passed (First M.B., Ch.B., Parts I. and II.). All communications respecting the Matriculation Examination, and examinations accepted in lieu thereof, must be sent to the Secretary, Joint Matriculation Board, 315, Oxford-road, Manchester. Second Examination.—Part I., Biology and Organic Chemistry; Part II., Anatomy and Physiology. Third Examination.—General Pathology and Bacteriology. Fourth Examinations (at the end of the fifth year).—Forensic Medicine and Toxicology; Public Health; and Materia Medica, Pharmacology and Therapeutics. Two years' hospital work must have been accomplished. Final Examination.—Medicine, Surgery, Midwifery and Diseases of Women, Mental Diseases, and Ophthalmology. Attendance at a general hospital for a year after the passing of the fourth examination will be required, also attendance at a fever hospital three months, maternity hospital three months, and mental hospital three months. Vaccination instruction must be taken and courses of Ophthalmology, Venereal and Skin Diseases, and Diseases of Ear, Nose, and Throat, Medical and Surgical Anatomy, and Operative Surgery. Distinctions may be awarded in the subjects (severally) of the Second, Third, Fourth, and Final, and First and Second-class Honours in the Final Examination.

Degrees of Doctor of Medicine and Master of Surgery. At the end of one year from the date of having passed the final M.B., Ch.B. examination the candidate will be eligible to present himself for the higher degrees of either Doctor of Medicine or Master of Surgery or both. Candidates have to present a thesis on some subject embraced in the medical curriculum, and pass a general examination in Principles and Practice of Medicine for the M.D., and one in Principles and Practice of Surgery, including operations on the cadaver, for the Ch.M., or, at the discretion of the examiners, in a special branch of Medicine or Surgery respectively. A thesis of exceptional merit may exempt from any part of these examinations, in which Honours may be awarded.

Degree of Ph.D.—The Degree of Doctor of Philosophy is conferred upon candidates who possess a medical degree of a British, Colonial, or other university approved of by the Senate of the University, and who have been engaged, to the satisfaction of the Medical Faculty, in advanced study and research for a period of not less than two years, either in a laboratory of the University or in one or more of the hospitals associated with the University. After the first year candidates may carry on research elsewhere, under approved conditions, and on completing the course present a thesis and submit themselves for oral and possibly written examination.

Scholarships and Prizes.—The following are awarded:—Entrance Scholarships: (*a*) Frank Fletcher and Catherine Fletcher Scholarships of £100 per annum each, for five years. Two or more offered annually; open to men and women students under certain prescribed conditions as to residence, &c.; (*b*) Sydenham Scholarship of £42, tenable for three years, award of Council to orphan sons of medical practitioners; (*c*) Sands Cox Scholarship of £21 per annum during two years, awarded to the candidate, not being more than 19 years of age, taking the highest marks at the Higher School Certificate Examination of the Joint Matriculation Board; (*d*) Dental Scholarship of £46 17*s.* 6*d.*, Open Competitive Examination in subjects learned during apprenticeship; (*e*) Myers Travelling Studentship of £300, tenable for one year, offered in alternate years, awarded by vote of committee to M.B., Ch.B. candidates, tenable at some University or Hospital not in Great Britain or Ireland (available for year 1929–30); (*f*) two Ingleby Scholarships of £10 each, awarded to the candidate at Final Examination obtaining highest "first-class" marks in the subjects of Midwifery and Diseases of Women; (*g*), (*h*), (*i*), and (*j*) Four Queen's Scholarships of £10 10*s.* each. In the Second, Third, and Fourth Examinations the Scholarship is awarded respectively to the student taking the first place and whose work is sufficiently distinguished. In the Final Examination the Scholarship is awarded to the candidate taking the first place in the examination and whose work is regarded as sufficiently distinguished. (*k*) George Henry Marshall Scholarship of £10, awarded annually, for the encouragement of Research Work in Ophthalmology; and (*l*) Russell Memorial Prize, a prize of books, value about £2, awarded annually to the student who, not being of more than six years' standing as a student of the School of Medicine of the University, shall pass the best examination in the subject of Nervous Diseases. The "*Arthur Foxwell Memorial Medal*" (Gold Medal for Medicine) is awarded annually to the candidate taking the highest place in Clinical Medicine and passing the Final M.B., Ch.B. Examination in June; and the "Sampson Gamgee Memorial Medal" (Gold Medal for Surgery) is awarded annually to the best candidates passing Final M.B., Ch.B. Examination in June in Surgery provided that not less than 60 per cent. of marks is obtained (paper, oral, and clinical). The University Clinical Board awards Gold and Silver Medals on examinations in Medicine, Surgery, and Midwifery, respectively, in fourth and fifth years, open to all students.

Clinical Instruction.—The medical students of the University receive their clinical instruction by attending the amalgamated practice of the General Hospital, Queen's Hospital, Maternity Hospital, Children's Hospital, Mental Hospital, and Fevers Hospital, under the direction of the University Clinical Board. Appointments are open to students varying from £40 to £200 a year.

Post-graduate Instruction.—A "William Withering Lectureship" has been established. A course (or courses) of lectures is given annually for post-graduates on subjects chosen from year to year. In 1930 the Lectures will be given by Dr. W. E. Dixon. The Ingleby Lectures on some subject in connexion with Diseases of Women and Children are given annually by specially appointed lecturers: The Lecturer for year 1930 is Sir John Bland-Sutton, Bart., LL.D., M.D., F.R.C.S. Post-graduate Courses of Clinical Demonstrations for General Practitioners are arranged annually (April to July) at the Birmingham General, Queen's, and Children's Hospitals.

QUEEN'S HOSPITAL.—330 beds. There is a close association of this Hospital with the University of Birmingham, and the University clinical teaching is conducted here, there being a wealth of excellent material. Ward rounds and out-patient clinic classes are held daily, and there are regular tutorial classes throughout the session. Post-graduate courses arranged by the University are conducted every year. There are special departments in Gynæcology, Diseases of the Eye, of the Ear, Nose and Throat, Dentistry, Radiography, Pathology, Bacteriology, Biochemistry, Physiotherapy, and Electrocardiography. There are also large Wards for Midwifery and Postnatal cases, a Nursery for instruction in Infant Welfare, an extensive Midwifery District, and residential facilities for students. There are 23 Resident Appointments (exclusive of Registrars) available each year for recently qualified students.

BIRMINGHAM GENERAL HOSPITAL.—406 beds. Special wards for Children, Gynæcological, Ear and Throat, Venereal, Maternity, and Septic cases; special beds for Eye and Skin cases. Laboratories for Bacteriology, Biochemistry, Cancer Research, and Morbid Histology. Separate rooms adjoin *the medical and surgical wards for clinical* pathology. Five operating theatres (one for out-patients), all designed and fitted on modern lines. In addition to clinical teaching given in the wards and out-patient department by the honorary staff, medical and surgical tutorial classes are held for senior and junior students. Clinical instruction in all the special departments, which include those for Radium, Electrotherapy, Electrocardiographic investigation, and Venereal Diseases. Post-graduate classes in every branch of medicine and surgery. The Jaffray Branch Hospital contains 61 beds.

Birmingham and Midland Eye Hospital, Church-*street, Birmingham.*—*115 beds.* Students attending for a period of three months will be granted certificates which will qualify for the University and Conjoint Board examinations. Post-graduate courses are available. A limited number of Non-Resident Clinical Assistants' posts are open to qualified practitioners, particulars of which can be had on application to the General Superintendent. This Hospital has a very large Out-patient Department.

UNIVERSITY OF LIVERPOOL.

The degrees in the Faculty of Medicine are Bachelor of Medicine and Bachelor of Surgery (M.B. and Ch.B.), Doctor of Medicine (M.D.), Doctor in Philosophy (Ph.D.), Master of Surgery (Ch.M.), Master of Hygiene (M.H.), and Master of Orthopædic Surgery (M.Ch.Orth.).

Matriculation.—Important alterations in regard to Matriculation requirements and to the First Year's course of study will come into operation in October, 1929. Particulars may be obtained on application to the Dean.

Degrees of Bachelor of Medicine and Bachelor of Surgery.—Candidates for the degrees of Bachelor of Medicine and of Surgery must have attained the age of 22 years on the day of graduation. At least two of the five years of medical study must have been passed in the University, and one year at least must have been passed in the University subsequently to the date of passing the First Examination. The other three years may be passed at any college or medical school recognised for this purpose by the University. Candidates must pass three examinations entitled respectively: the First Examination, the Second Examination, and the Final Examination. The subjects of the First Examination are: (1) Chemistry; (2) Biology (Zoology and Botany); (3) Physics; (4) Special Chemistry. The subjects of the Second Examination are (*a*) (1) Anatomy; (2) Physiology (including Physiological Chemistry and Histology); and (*b*) (3) Elementary Bacteriology, (4) Clinical Chemistry, (5) General Pathology. Candidates may present themselves in (*a*) or (*b*) separately. The subjects for the Final Examination are: (*a*) (1) Special Pathology and Morbid Anatomy; (2) Forensic Medicine and Toxicology; (3) Public Health; (4) Pharmacology and General Therapeutics; (*b*) (5) Obstetrics and Diseases of Women; (6) Surgery, Systematic, Clinical, Operative and Practical, including Ophthalmology; (7) Medicine, Systematic and Clinical, including Therapeutics, Mental Diseases, and Diseases of Children. Candidates may present themselves in Parts (*a*) and (*b*) separately, but candidates must have completed the fifth year of medical study before taking Part (*b*).

Degrees of Doctor of Medicine and Master of Surgery. No candidate will be admitted to the degree of Doctor of Medicine or Master of Surgery unless he has previously received the Degrees of Bachelor of Medicine and Bachelor of Surgery, and at least two years have elapsed since he passed the examinations for those degrees. Candidates for the degree of Doctor of Medicine are required (*a*) to present a thesis, acceptable to the Faculty, and certified to be the candidate's own work, together with (if the candidate desires) copies of published original papers upon Medical Science; (*b*) to present themselves for an *oral examination on the subject of the thesis.*

The University also awards a *Diploma in Medical Radiology and Electrology*—Part I., Physics: Part II., Radiology and Electrology. The parts may be taken at one examination or separately.

Scholarships, Fellowships, and Prizes.—The following are awarded: (*a*) Robert Gee Entrance Scholarship (Men), annually, of £42 10*s.*, tenable for four years; (*b*) Lyon Jones Scholarship, No. 1, of £21 per annum, tenable for two years, Competitive Examination among Junior Students in First M.B. Subjects; (*c*) Lyon Jones Scholarship, No. 2, of £21, Competitive Examination on results of Professional Examination in Anatomy, Physiology, Elementary Bacteriology, Clinical Chemistry, and General Pathology; (*d*) Derby Exhibition of £15, Competitive Examination in Clinical Surgery, and (*e*) Clinical School Exhibition of £15 in Clinical Medicine; (*f*) University Scholarship of £50 for one year, awarded on results of the Final (Part A) Examination for the degrees; (*g*) Holt Fellowships, Physiology and Pathology, of £150 each, for one year; (*h*) Gee Fellowship, Anatomy, of £100, for one year; (*i*) John Rankin Fellowships in Anatomy, two, each of the value of £120, tenable for two years; (*j*) Johnston Colonial Fellowship, Biochemistry, of £100, for one year; (*k*) John W. Garrett International Fellowship, Bacteriology, of £100, for one year; (*l*) Thelwall Thomas Fellowship, Surgical Pathology, of £150, for one year; (*m*) Ethel Boyce Fellowship in Gynæcological Pathology, of £100 for one year; (*n*) Mary Birrell Davies Memorial Fund Scholarship, of the value of £60, tenable for four years, offered for competition in alternate years; open only to women students who will have attained the age of 19 on the first day of October next following the award; (*o*) Rankin Exhibition in Practical Anatomy, of £25, for one year; (*p*) Lady Jones Research Fellowship in Orthopædic Surgery, £200; (*q*) Samuels Memorial Scholarships, three at £20; (*r*) Ridgway Research Scholarship (£100); numerous prizes and medals.

The Medical School.—All the laboratories and classrooms are situated close together, communicating with one another, and are made up of four large blocks of buildings which form one side of the College quadrangle. There are the Johnston Laboratories for Experimental Medicine and Biochemistry; the Medical School for Anatomy, Surgery, Toxicology, and Ophthalmology; and the Thompson-Yates Laboratories for Physiology and Pathology. There is also a separate building for Tropical Medicine. Medical research has also been endowed with several new laboratories in which students can pursue research work after graduation.

Clinical Studies.—The Clinical School of the University consists of four general hospitals—the Royal Infirmary, the David Lewis Northern Hospital, the Royal Southern Hospital, and the Stanley Hospital; and of five special hospitals—the Eye and Ear Infirmary, the Hospital for Women (with the Samaritan Hospital), Liverpool Maternity Hospital, the Royal Liverpool Children's Hospital, and St. Paul's Eye Hospital. These hospitals contain in all a total of about 1445 beds. The organisation of these hospitals to form one teaching institution provides the medical student and the medical practitioner with a field for clinical education and study which is unrivalled in extent in the United Kingdom. All the hospitals are within easy access of the University. There are a large number of appointments to house physicianships and surgeonships both at the general and special hospitals which are open to qualified students of the school.

Public Health Department.—This is located in a separate building, in which full courses of instruction are given to students for the Diplomas and Degrees of the University and of other Examining Boards.

Prospectuses and further information may be had on application to the Dean of the Faculty of Medicine, University of Liverpool.

VICTORIA UNIVERSITY OF MANCHESTER.

Four degrees in Medicine and Surgery are conferred by the University—viz., Bachelor of Medicine and Bachelor of Surgery (M.B. and Ch.B.), Doctor of Medicine (M.D.), and Master of Surgery (Ch.M.). A Diploma in Psychological Medicine, a Diploma in Public Health, and a Diploma in Bacteriology are awarded by examination to registered medical practitioners.

Degrees of Bachelor of Medicine and Bachelor of Surgery.—Before admission to the degree of M.B. or Ch.B. candidates are required to present certificates that they will have attained the age of 21 years on the day of graduation, and that they have pursued the courses of study required by the University Regulations during a period of not less than five and a half years subsequently to the date of their registration by the General Medical Council, two of such years having been passed in the University subsequently to the date of passing the first M.B. Examination.

The First Examination: (1) Chemistry and Physics; (2) (*a*) Botany, (*b*) Zoology. Candidates must have attended during at least six months' courses both of lectures and of laboratory work in each of the above-named subjects. The Examination is divided into two parts: Part 1, Inorganic and Elementary Organic Chemistry and Physics; Part 2, (*a*) Botany, (*b*) Zoology. The candidates sit for these parts separately. The Second Examination: (1) Anatomy and Histology; (2) Physiology, including Physiological Chemistry. Bothparts must be passed simultaneously. The Third Examination: (1) Pharmacology and Materia Medica; (2) Pathology and Bacteriology. The Final Examination: (1) Medicine, Systematic and Clinical (including Mental Diseases and Diseases of Children); (2) Surgery, Systematic, Clinical, and Practical; (3) Obstetrics and Gynæcology (including Clinical and Practical); (4) Forensic Medicine (including an Oral Examination); (5) Hygiene and Preventive Medicine. The Final Examination is divided into two parts: Part I., Forensic Medicine, Hygiene and Preventive Medicine; Part II., Medicine, Surgery, Obstetrics and Gynæcology (Systematic, Clinical, and Oral). Candidates must pass in all subjects of Part I. and of Part II. simultaneously. Candidates for the Second Part must have completed the sixth year of medical study.

Degree of Doctor of Medicine.—Candidates are not eligible for the degree of Doctor of Medicine unless they have previously obtained the degrees of Bachelor of Medicine and Bachelor of Surgery and at least one year has elapsed since they passed the examination for those degrees. Candidates may elect either (1) to present an original dissertation; or (2) to undergo an examination. The dissertation must embody the results of personal observation or original research, either in some department of medicine or of some science directly relative to medicine. The examination, which will be written and practical, is in the Principles and Practice of Medicine, in Pathology, and in some other subject to be selected by the candidate.

Degree of Master of Surgery.—Candidates are not eligible for the degree of Master of Surgery unless they have previously obtained the degrees of Bachelor of Medicine and Bachelor of Surgery and at least one year has elapsed since they passed the examination for those degrees. The degree is conferred in the following branches: Surgery (Branch I.), Gynæcology (Branch II.), Ophthalmology (Branch III.), Laryngology, Otology, and Rhinology (Branch IV.).

Degrees of B.Sc. and M.Sc.—The ordinary degree of B.Sc. in the Schools of Anatomy and Physiology may be obtained by students in Medicine who in their third year of study for the degree of M.B., Ch.B. complete the additional courses in these subjects prescribed for this degree. Candidates for the Honours degree of B.Sc. in Anatomy or Physiology, who are students in Medicine, are required to attend courses in advanced Anatomy and Physiology for four terms after passing the Second Examination for the degrees of M.B., Ch.B. Graduates in science may proceed to the degree of M.Sc. by presentation of an approved thesis.

Diplomas: 1. The following are available for candidates holding a registrable qualification in medicine, surgery, and midwifery; examinations are in two parts in each diploma and are written, oral and practical. Candidates may present themselves for Parts I. and II. separately or at the same time provided that no candidate be admitted to Part II. unless he has already passed in Part I. No candidate's name will be published until he has satisfied the examiners in both parts of the examination:—

(*a*) *Diploma in Psychological Medicine.*—Part-time course: extending over three University terms, two of which must be spent at the University. Six months' residence must be spent at a recognised Hospital for Mental Diseases.

(*b*) *Diploma in Public Health.*—The course extends over twelve calendar months at least: Part I. of the examination is held in June and October, and Part II. in March and October. Instruction for at least one of the parts must be taken out at the University. Holders of the Diploma in Public Health are eligible for examination for the Certificates in School Hygiene and Factory Hygiene after attending the prescribed periods of study and hospital practice.

2. *In Veterinary State Medicine.*—Length of course, three University terms. Candidates must be members of the Royal College of Veterinary Surgeons.

3. *In Bacteriology.*—For candidates who have graduated either in science or medicine, or obtained other approved qualification. Length of course, one academic year. A satisfactory thesis on an approved subject must be presented.

Scholarships, Fellowships, and Prizes.—The following are offered in connexion with medical study at the Victoria University:—Scholarships: Dreschfeld Entrance (triennial), £20; John Russell Medical Entrance, £45; Sam Gamble Entrance for Women; Graduate Entrance (fees up to 160 guineas); two Dauntesey Medical Junior, £50 each; Dauntesey Medical Senior, £50; Professor Tom Jones Exhibition in Anatomy, £25; Dickenson Trust Scholarships in Anatomy and Pathology; Platt Physiological, £90; Graduate Research Scholarship, £70; Dickenson Trust Travelling Scholarships in Medicine and Surgery; Ashby Memorial in Diseases of Children (triennial), £100; John Henry Agnew in Diseases of Children, £120. Fellowships: Leech Research, £70; Professor Tom Jones, Surgical, £105; Morrison Watson in Anatomy, £150; Delépine in Preventive Medicine (biennial), £300; Worswick (Causes and Treatment of Rheumatoid Arthritis), £300; Zimmern Travelling Fellowship for Men, £175; Honorary Research Fellowships. Prizes: Sidney Renshaw in Physiology, £15; Wild Prize in Pharmacology, £10; Turner Medical, £20; Dumville Surgical, £15; Knight Prize in Psychological Medicine, £50; Graduate Prizes, £5 each. There are many general entrance scholarships, in addition to those already mentioned, open for competition, the examinations for which are held in the month of May. Full particulars can be obtained from the Registrar.

The Medical School.—This school, largely extended in 1920, is provided with dissecting-rooms, X ray rooms, physiological laboratories, private laboratories, and work-rooms, besides lecture-rooms, museums, and general and departmental libraries. A special laboratory is equipped for experimental work on the central nervous system. In the pathological laboratories (now removed to special buildings close to the Royal Infirmary) ample provision is made for the teaching of pathology and bacteriology and for the prosecution of original research. The Helen Swindells Laboratory is specially equipped for cancer research and investigation in general pathology. Ample facilities for investigation are provided in Anatomy, Physiology, and Materia Medica; new Pharmacological Laboratories have been added this year. In the public health department, which is lodged in a separate institute in York Place, near the Royal Infirmary, suitable laboratory accommodation is provided for the study of sanitary chemistry, physics, and practical bacteriology in the departments of chemistry and physics and in that of pathology.

Clinical Studies.—The clinical and practical departments of medical study are taught partly in the Medical School and partly in the Royal Infirmary and St. Mary's Hospitals for Women and Children, a fever hospital, mental hospitals, a convalescent home, and other special hospitals. Medical and Surgical Clinical Classes are conducted in the Infirmary, and separate instruction is afforded in the elements of Medical and Surgical Physical Diagnosis, in Obstetric Medicine, Ophthalmic Surgery, and Pathological Anatomy by the different members of the staff of the Medical School and Infirmary.

Post-graduate Studies.—Post-graduate Courses in the following subjects have been arranged for during 1929-30, in addition to those usually held at the various hospitals: 1. Whole-time intensive courses in (i.) Obstetrics, (ii.) Medicine and Surgery, (iii.) (*a*) Fractures, (*b*) Oto-Laryngology. 2. A Post-graduate Day. 3. Part-time courses in (i.) Diseases of the Eye, (ii.) Diseases of the Skin, (iii.) Bacteriology and Immunity. 4. Clinical Assistantships. Syllabuses and other information may be obtained on application to the Dean of the Medical School, Manchester University.

MANCHESTER ROYAL INFIRMARY.—The Manchester Royal Infirmary is built on the pavilion system, near the University, and has accommodation for 608 patients (including 54 beds at the Central Branch). The medical side consists of four units, each unit having a testing-room for the scientific investigation of morbid products and a class-room. The surgical beds are arranged in five units, each unit having its own operation theatre, with anæsthetising, recovery, sterilising, testing and apparatus rooms, and its own class-room attached. All of these units are occupied. In the educational block is a large lecture theatre and a museum. In the same building is housed the X ray department, which has nine separate X ray outfits for different purposes, and in which one large room is put aside specially for X ray demonstrations and teaching purposes. A large massage school is also connected with this department.

Associated with the Infirmary are: (1) the Convalescent Hospital at Cheadle, containing 132 beds; and (2) the Central Branch in the City, which has now accommodation for 54 patients. The Associated Hospitals thus contain 800 beds and are under the same management. Women students are admitted on the same terms as men.

Two Entrance Scholarships in Medicine of the value of £100 each are offered annually by the Council of the Manchester University and the Medical Board of the Manchester Royal Infirmary for proficiency in Arts and Science subjects respectively. Other scholarships and prizes are mentioned in the College syllabus. Numerous annual appointments and junior appointments may be held by those who have attended the practice of the Infirmary.

ROYAL MANCHESTER CHILDREN'S HOSPITAL, Pendlebury, Gartside-street, Manchester, and Lytham St. Anne's.—The hospital contains 190 beds and 80 in the Convalescent Home, Lytham St. Anne's. The medical staff visit the hospital daily at 10 A.M. Clinical instruction is given by the medical staff at the Hospital and Dispensary. There is a new Massage and Electrotherapeutic Department, also an Artificial Sunlight Department. Clinical Assistants are appointed for periods of six months. In throwing open these appointments to qualified medical men and women, the Board is actuated by the desire to aid those qualified medical men and women who wish to have opportunities for the further study of disease in children, or who wish to fit themselves for posts as Medical Officers to Children's Hospitals, to Child Welfare Centres, or for School Medical Officer appointments. There is an Orthopædic Department. Out-patients' day is on Tuesday at Gartside-street, and a ward at Pendlebury is devoted to cases needing operative treatment. Out-patients are seen daily at 9 A.M. at the Out-patient Department, Gartside-street, Manchester. Secretary: Mr. W. M. Humphry.

ANCOATS HOSPITAL, MANCHESTER (Founded 1828).—114 beds with a Convalescent Branch of 85 beds at Great Warford, Alderley Edge, Cheshire.

The hospital will be extended during the next two years by the addition of a new ward block, an operating theatre block, pathological department, physiotherapeutic department, and lecture theatre.

The medical division consists of three units served by consultative out-patient clinics. One unit includes a cardiological department; another devotes special attention to gastro-enterology; and the third to neurology. The surgical division comprises an orthopædic unit in which all the fractures and injuries of the hospital are treated; a unit devoted particularly to urology; a unit devoted to abdominal surgery; and an oto-laryngological unit. All units include out-patient clinics. A special clinic staffed by a team consisting of surgeons, pathologist, radiologist, and consultant in radium therapy has recently been created for the study and treatment of malignant disease. The demand on the surgical in-patient accommodation is great, 800 patients at the present time being on the waiting-list. Clinical teaching is given both to undergraduate and post-graduate students in all out-patient clinics, in the wards, and in the form of special lectures. The under-graduate teaching includes a University course in Orthopædic Surgery given in the Michaelmas term, and demonstrations on the examination of the ear, nose and throat. The hospital takes an important share in the University of Manchester Post-graduate scheme. A post-graduate "day," open to all practitioners without fee, is held on each Thursday in the University terms. During the session (1929-30) special intensive post-graduate courses will be given in the treatment of Fractures (Oct. 7th–11th), and in Oto-Laryngology (March 3rd–8th). Applications for entry to these courses should be made to the Dean of the Faculty of Medicine, University of Manchester.

There are six residents: a resident surgical officer, a resident medical officer, three house surgeons, and one house physician. These appointments are open both to men and women graduates, and are recognised by the University of London for the purposes of the M.D. and M.S. degrees. There are also four registrar appointments (part time): medical, orthopædic, surgical, and pathological. These are made annually, and are renewable up to a period of three years. General Superintendent and Secretary: Herbert J. Dafforne.

MANCHESTER NORTHERN HOSPITAL FOR WOMEN AND CHILDREN, Park-place, Cheetham Hill-road, Manchester.—The hospital contains 73 beds. Out-patients are seen daily from 8.30 to 12 noon.

UNIVERSITY OF LEEDS.

Four degrees in Medicine and Surgery are conferred—viz.: Bachelor of Medicine and Bachelor of Surgery (M.B. and Ch.B.), Doctor of Medicine (M.D.), Master of Surgery (Ch.M.), also Degrees and Diplomas in Dental Surgery and Diplomas in Public Health and in Psychological Medicine. The courses and Degrees in the Faculty are open to men and women alike.

Degrees of Bachelor of Medicine and Bachelor of Surgery.—Candidates for these degrees are required to present certificates showing that they will have attained the age of 21 years on the day of graduation, and have attended courses approved by the University extending over not less than five years, two of such years at least having been passed in the University, one of which must be subsequent to the date of passing the First Examination. Candidates must also satisfy the examiners in the several subjects of the following examinations, entitled respectively: the

Matriculation Examination, or such other examination as may have been recognised by the Joint Matriculation Board in its stead; the First Examination; the Second Examination; and the Final Examination. The First Examination consists of: Part I., Physics and Inorganic Chemistry; Part II., Zoology and Botany. Candidates will be allowed to pass the two parts separately. The Second Examination consists of: Part I., Organic Chemistry; Part II., Materia Medica and Practical Pharmacy; Part III., Anatomy, Physiology. Candidates will be allowed to pass any parts separately, but Part I. must be passed before Parts II. or III. The Final Examination consists of: Part I., Pharmacology, Pathology and Bacteriology; Part II., Medicine, Surgery, Obstetrics, Gynæcology, and Clinical Pathology; Part III., Forensic Medicine, Public Health, and Therapeutics. Part I. may be taken at the end of the second clinical year, and Parts II. and III. may be taken at the end of the third clinical year, but not before the completion of the fifth year of medical study. If taken separately Part II. may be passed before Part III.

Degree of Doctor of Medicine and Master of Surgery.—Candidates are not eligible for the degree of Doctor of Medicine or Master of Surgery unless they have previously received the degrees of Bachelor of Medicine and Bachelor of Surgery of the University (or of Victoria prior to December, 1904) and at least two years' Hospital Practice or four years' other professional practice for the former, and one year has elapsed for the latter since they passed the examination for those degrees. Candidates for the degree of Doctor of Medicine may present a dissertation and, if the dissertation is considered to be of exceptional merit, will not be required to pass an examination. The first term commences on Oct. 1st. Prospectus can be obtained from the Academic Sub-Dean.

Post-graduate work.—Practitioners wishing to attend Infirmary practice during short periods, or post-graduate classes held by members of the clinical staff, may do so on application to the Clinical Sub-Dean, from whom particulars may be obtained.

Clinical Studies.—The clinical studies are pursued mainly at the LEEDS GENERAL INFIRMARY, which has accommodation for 630 in-patients, including 88 beds at branch hospitals in the country. Clinical teaching takes place daily in the wards, and Clinical lectures are given in Medicine and Surgery by the Physicians and Surgeons. There are Medical, Surgical, Ophthalmic, Aural, Electrotherapeutic, and Radiographic Departments, in each of which special instruction is imparted to students. Gynæcological and Children's Departments, together with Laryngeal, Venereal, and Skin Clinics, are in operation, and there is a special ward for cases of nutritional disorders of children. Several valuable prizes are given at the end of each session. Numerous appointments at the Infirmary are annually open to students after qualification. Further particulars concerning these, and the scholarships and prizes open to competition, may be obtained from the Dean of the Faculty of Medicine.

In addition to work in the General Infirmary, clinical instruction in obstetrics is given in the Leeds Maternity Hospital and in mental and infectious diseases in the Wakefield (W.R.) Mental Hospital and Leeds City Fever Hospital respectively.

UNIVERSITY OF SHEFFIELD.

The Degrees in the Faculty of Medicine are Bachelor of Medicine and Bachelor of Surgery (M.B., Ch.B.), Doctor of Medicine (M.D.), and Master of Surgery (Ch.M.), Bachelor of Dental Surgery (B.D.S.), and Master of Dental Surgery (M.D.S.). There is also a Diploma of Licentiate in Dental Surgery. The courses and degrees in the Faculty of Medicine are open to men and women alike. Candidates must matriculate in the University or pass such other examination as may be recognised for this purpose by the University and sanctioned by the Joint Matriculation Board, and must pass also the further examination in Chemistry and Physics.

Degrees of Bachelor of Medicine and Bachelor of Surgery.—A candidate must have attained the age of 22 years on the day of graduation and have pursued the courses of study required by the University regulations during a period of not less than five years subsequently to the date of his matriculation and the passing of the further examination in Chemistry and Physics, three of such years at least having been passed in the University, one at least being subsequent to the passing of the First Examination. The subjects of the First Examination are Chemistry, Physics, and Biology. The Intermediate B.Sc. Examination in these subjects will, on payment of the required additional fee, be accepted instead of this examination. Candidates must, after matriculation and the passing of the further examination in Physics and Chemistry, and registration as medical students, have attended courses of instruction (lectures and laboratory work) in chemistry, physics, and biology for one year each. The Second Examination: The subjects are Anatomy and Physiology. Candidates must have completed the second year of professional study. The Third Examination: The subjects are Pathology, Pharmacology, Anatomy, and Physiology. Candidates must have completed the Lent Term of the fourth year of professional study. The Final Examination: The subjects of the examination are: Part I., Forensic Medicine and Public Health; Part II., Medicine (including Mental Diseases and Diseases of Children), Surgery, Obstetrics (including Gynæcology). Candidates for Part I. must have completed the Michaelmas Term of the fifth year of professional study; candidates for Part II. must have completed the fifth year of professional study.

Degree of Doctor of Medicine.—Candidates for the degree of Doctor of Medicine must have passed the examination for the degrees of M.B., Ch.B. at least one year previously, must present a thesis embodying observations in some subject approved by the professor of medicine, and must pass an examination in the Principles and Practice of Medicine.

Degree of Master of Surgery.—Candidates must have taken the M.B., Ch.B. at least one year previously, and must since have held for not less than six months a surgical appointment in a public hospital.

The subjects of examination are Systematic, Clinical, and Operative Surgery, Surgical Anatomy, Surgical Pathology and Bacteriology.

Scholarships and Prizes.—The following are awarded: Four Town Trustees scholarships, offered annually, each of the value of £50 per annum for three years. Medical: offered annually, covers cost of medical curriculum. Six Edgar Allen, offered annually, each of the value of £125 per annum for three years. Post-graduate: Frederick Clifford scholarship, value £50 per annum, tenable for two years. Mechanics' Institute scholarship, value £50 for one year, renewable for a second year. Town Trustees fellowship, value £75 for one year. Medals and Prizes: Kaye scholarship; Gold Medal in Clinical Medicine and Surgery; John Hall Gold Medal in Pathology; Holroyd Gold Medal in Anæsthetics; bronze medals. Particulars of all the above may be obtained from the Registrar.

The Medical School.—The Medical Department occupies the entire north wing of the University quadrangle. The various athletic and other students' societies are under the management of the Union Representative Council, elected annually. There are large and comfortable common rooms both for men and women students, and two Students' Unions, one for men and one for women. A refectory is open daily at the University where students may obtain meals and refreshments at moderate prices. The University journal *The Arrows*, edited by a committee of staff and students, is published each term. The University Halls, "Oakholme," Clarkehouse-road; "Tapton Cliffe," Fulwood-road, and "Endcliffe University Hall," Endcliffe Vale-road, are recognised by the Senate as halls of residence for women students; full particulars may be obtained from the tutor for women students.

Stephenson Hall is a hall of residence for men students; particulars may be obtained from the Warden.

Clinical Studies.—The University is within easy reach of the various hospitals with which it is connected for clinical purposes.

The Sheffield Royal Infirmary (500 beds) provides all the opportunities of a large general hospital with special departments for Skin and Ear. The Sheffield Royal Hospital, 320 beds, has special out-patient departments for Diseases of the Throat, Ear, Skin, Orthopædics, and Mental Diseases. The two institutions are amalgamated for the purposes of clinical practice, medical, surgical, and special. There are special departments for the treatment of Diseases of the Eye, with wards assigned to them, at both hospitals, and excellent junior appointments. The Jessop Hospital for Diseases of Women, with 145 beds, has also a Maternity department, with about 900 in-patients per annum and about 250 out-patient cases attended. The Children's Hospital has 85 beds. Special courses on Fevers are held at the City Fever Hospitals (690 beds) and on Mental Diseases at the South Yorkshire Mental Hospital (1800 beds). Every facility is afforded in the various laboratories for the prosecution of advanced studies and research.

Post-graduate Courses.—Post-graduate courses of clinical instruction are held annually in the various hospitals connected with the School.

UNIVERSITY OF BRISTOL.

In the Faculty of Medicine there are the following degrees:—Bachelor of Medicine and Bachelor of Surgery (M.B. and Ch.B.), Doctor of Medicine (M.D.), Master of Surgery (Ch.M.), Bachelor of Dental Surgery (B.D.S.), and Master of Dental Surgery (M.D.S). There are also the following diplomas: Diploma in Public Health (D.P.H.), Diploma in Dental Surgery (L.D.S.), and Diploma in Veterinary State Medicine.

All candidates for degrees in Medicine, Surgery, and Dentistry are required to pass, at Matriculation standard, an examination called the School Certificate Examination, or to pass such examination as may be regarded as equivalent by the Senate. All courses, degrees, and diplomas are open to men and women alike.

Degrees of Bachelor of Medicine and Bachelor of Surgery.—Candidates shall be not less than 21 years of age and shall have pursued the courses prescribed by University Regulations during not less than five years after passing the first examination in Chemistry and Physics, and entrance on the professional curriculum at the University, or an institution recognised as equivalent, of which three shall have been passed in the University, and two of these three subsequent to passing the second examination. All candidates for the degrees of M.B., Ch.B., are required to satisfy the examiners in the several subjects of three examinations. The First Examination: The subjects of examination are: Chemistry (Inorganic), Physics, and Biology, the courses pursued being those for the time being approved for the intermediate part of the B.Sc. curriculum. This part of the curriculum shall extend over one year. (Candidates who have passed the Higher School Certificate approved by the Board of Education in these subjects will not be required to sit for the first examination and will be regarded as having completed one year of study.) The Second Examination: The subjects of examination are: Organic Chemistry and Elementary Anatomy (Part I.) and Advanced Anatomy and Physiology (Part II.). The Final Examination: The subjects of examination are: Materia Medica and Pharmacy, Pharmacology and Therapeutics, General Pathology, Morbid Anatomy, and Bacteriology (Part I.); Special Pathology, Forensic Medicine, Toxicology, and Public Health, Obstetrics (including Diseases of Women), Surgery (Systematic, Clinical, Practical, and Operative), Medicine (Systematic, Clinical, and Practical, including Mental Diseases) (Part II.). The subjects included in Part II. may be taken in two groups—viz., Group I., Surgery and Obstetrics; Group II., Medicine, Public Health, Special Pathology, Forensic Medicine, and Toxicology. Candidates may pass Parts I. and II. together, or separately, and the two groups of Part II. may be taken together or separately. Forensic Medicine and Toxicology may be taken with Part I., or with Group II. of Part II.

Degree of Doctor of Medicine.—Candidates shall be Bachelors of the University of not less than two years' standing as such and may elect either (1) to pass an examination in General Medicine, or (2) to pass an examination in State Medicine, or (3) to present a Dissertation. The candidate who elects to pass the examination in State Medicine must hold a diploma in Public Health of some University or College, and the candidate who elects to present a Dissertation may be examined in the subject thereof.

Degree of Master of Surgery.—Candidates shall be Bachelors of not less than two years' standing as such, during which period they shall have attended the Surgical Practice of an institution approved for the purpose. They shall pass an examination in Surgical Anatomy, Pathology, and Bacteriology, and Operative, Clinical, and General Surgery, and present to the University a Dissertation on some subject of Surgery. The degree may be taken also in General Surgery, and a Special Subject—e.g., Oto-Rhino-Laryngology, Ophthalmology, and Gynæcology.

Clinical Studies.—The allied hospitals (Bristol Royal Infirmary and Bristol General Hospital) have between them about 600 beds and extensive out-patient departments, special clinics for Diseases of Women and Children and those of the Eye, Throat and Ear, in addition to large and well-equipped departments for Dental work and large outdoor Maternity Departments.

At each of these institutions there are well-arranged pathological museums, post-mortem rooms, and laboratories for Morbid Anatomy. There are also laboratories for work in Clinical Pathology, Bacteriology, and Cytology, in which special instruction is given in these subjects. Departments are provided and well equipped for X ray work, both for diagnosis and treatment, the various forms of Electrical treatment, including High-frequency Currents, Electric Baths, Finsen Light treatment, and Massage.

The students of the school also attend the practice of the Royal Hospital for Sick Children and Women, containing 140 beds, and that of the Bristol Eye Hospital with 40 beds, and the Southmead Hospital with 556 beds, may be visited.

There are numerous salaried junior appointments for residents who are graduates.

Scholarships and Prizes.—The following are awarded: The Ashworth Hallett Scholarship, value £45, open to women only; two Martin Memorial Pathological Scholarships of £10 each; the Tibbits Memorial Prize, value 9 guineas, for proficiency in practical surgery; the Committee's Gold and Silver Medals for fifth-year students for general proficiency; the Augustin Prichard Prize, value about 6 guineas, for proficiency in anatomy; the Henry Clark Prize, value 11 guineas, for proficiency in gynæcology; the Crosby Leonard Prize, value 7 guineas, for proficiency in surgery; the Suple Surgical Prize, a gold medal and 7 guineas; the Suple Medical Prize, a gold medal and 7 guineas; the Henry Marshall Prize, value £12, for dressers; the H. M. Clarke Scholarship, value £15, for proficiency in surgery; the Sanders Scholarship, value £22 10*s.*, for general proficiency; the Barrett-Roué Scholarship for proficiency in diseases of the eye, ear, nose, and throat, value £14; Lady Haberfield Scholarship, value about 25 guineas.

Bristol City Senior Scholarships and those offered by the counties of Gloucestershire, Somerset, Wilts, and Devon, are tenable in the University. Some of the Fellowships awarded by the Colston Research Society for research in the University and the Beaverbrook Fellowship are allotted to the Faculty of Medicine.

Post-graduate Study.—Qualified medical practitioners may be appointed as clinical assistants for a period of one or more months. They may act as assistants, if times permit, in more than one department and in any of the hospitals during their period of study. They will be entitled to the use of the clinical laboratories and medical library, and have the right to attend in all departments, including operations, post-graduate and ordinary clinical demonstrations, and post-mortem examinations. Demonstration courses with weekly lectures are held during May, June, and July.

All inquiries and applications for admission should be addressed to the Director of Post-graduate Studies (Clinical Section), Pathological Department, University of Bristol, who can be seen on any day by appointment.

Further information as to scholarships, curricula, and fees can be obtained from the Dean of the Faculty of Medicine or the Registrar of the University.

UNIVERSITY OF WALES.

This University has, inter alia, the privilege of granting Degrees in Medicine, and Diplomas in Public Health and Tuberculous Diseases. Preliminary courses of study for the Degrees in Medicine may be pursued at any of the constituent Colleges of the University—viz., at Aberystwyth, Bangor, Cardiff, or Swansea. The Welsh National School of Medicine is situated in Cardiff and is an integral part of the University College of South Wales and Monmouthshire there.

Particulars can be obtained on application to the Registrar of the University of Wales, University Registrary, Cathays Park, Cardiff, or the Dean of the Faculty of Medicine, or to the Secretary, Welsh National School of Medicine, Newport-road, Cardiff. All classes are open to both men and women students.

ENGLISH MEDICAL CORPORATIONS GRANTING DIPLOMAS.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGE OF PHYSICIANS OF LONDON AND THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

Under this heading we give the regulations for the examinations enjoined by the Conjoint Examining Board of the Royal Colleges of Physicians of London and Surgeons of England, and of the Society of Apothecaries upon students desiring their respective diplomas of qualification. We do not give any list of schools recognised by these bodies as eligible to prepare students for their examinations beyond mentioning that all the schools which we have already described (under the heading of the Universities to which they are attached) are recognised as suitable places of instruction by the corporations granting medical diplomas. The courses of study at the principal colonial medical schools are also recognised as qualifying for the examinations of these corporations.

Students are required to pass a Preliminary Examination in General Education recognised by the Board, and a *Pre-Medical Examination* in Chemistry and Physics conducted by the Conjoint Examining Board before commencing the five years curriculum of professional study or some other examination recognised by the Board—namely, the examination in Chemistry and Physics for the degree in Medicine of any University recognised by the Board; a Pre-Medical Examination conducted by any of the Qualifying Bodies whose Degrees or Diplomas are registrable on the Medical Register; the Higher School Certificates of Oxford and Cambridge Universities, and the Oxford and Cambridge Schools Examination Board; the Higher Certificates of London, Bristol, Durham Universities, the Joint Matriculation Board of the Northern Universities, and the Central Welsh Board Higher Certificate. A candidate must enter for Chemistry and Physics together, and he will not be allowed to pass in one without obtaining at the same time at least half the number of marks required to pass in the other subject. He will be admitted to the examination on producing evidence of having passed the required Preliminary Examination in General Education. The examination is partly written, partly oral, and partly practical. A candidate rejected in one or both subjects of the examination will not be admitted to re-examination until after the lapse of a period of not less than three months. The fee for the examination is £3 3*s.*, for re-examination in Chemistry £2 2*s.*, and for re-examination in Physics £1 1*s.*

There are two Professional examinations called the *First* and *Final Examinations*. The courses of study for these examinations may be commenced before the Pre-Medical examination in Chemistry and Physics or some equivalent examination has been passed, provided that three terms of study are completed after the examination has been passed.

The subjects of the First Professional Examination are: Section I. (*a*) Anatomy, including Histology and Embryology. (*b*) Physiology, including Biochemistry. Section II. Pharmacology, Practical Pharmacy, and Materia Medica. A candidate must have attended at a recognised Medical School courses of instruction in Anatomy, including Embryology, during five terms, during which he must have dissected the whole body, courses of instruction in Physiology, including General Biology, Biochemistry and Biophysics during five terms, courses of instruction in Pharmacology, Practical Pharmacy, and Materia Medica. A candidate may present himself for the two Sections together or separately, but he must take parts (*a*) and (*b*) of Section I. together until he has passed in one or both parts, but a candidate will not be allowed to pass in one part unless he obtains at the same time at least half the number of marks required to pass in the other part.

Section II. of the examination may be passed at any time before the candidate enters for the Final Professional Examination. The fee for the First Professional Examination is £10 10*s.*, for re-examination after rejection in Section I. £6 6*s.*, for re-examination after rejection in either part of Section I. £3 3*s.*, for re-examination after rejection in Section II. £3 3*s.* A candidate who produces satisfactory evidence of having passed an examination in the subjects of Section I. or of either part of Section I. and of Section II. in the examination for the degree in Medicine conducted at a University recognised by the Board will be exempted from further examination in such subjects.

Final Professional Examination.—The subjects of the Final Professional Examination are: Section I. Pathology (including Morbid Anatomy, Morbid Histology, and Clinical Pathology), and Bacteriology. Section II. Part I. Medicine, including Medical Anatomy, Forensic Medicine and Public Health. Part II. Surgery, including Surgical Anatomy and the use of Surgical Appliances. Part III. Midwifery and Gynæcology. The examination is partly written, partly practical, partly clinical, and partly oral. A candidate may take Sections I. and II. and the three parts of Section II. of the Final Examination separately or may take the whole examination together. He will be required to produce the certificates required by the regulations before being admitted to the respective parts of the examination. A candidate who produces evidence of having passed an examination for a degree in medicine in the subjects of Pathology and Bacteriology at a University recognised by the Board is exempted from *Section I.* The fee for admission to Section I. is £4 4*s.*; for admission to Section II., Part I., £10 10*s.*; Part II.,

£10 10*s.*; Part III., £6 6*s.*; and the re-examination fees are respectively £3 3*s.*, £6 6*s.*, £6 6*s.*, and £4 4*s.*

Students of recognised universities in England, Scotland, and Ireland, who have passed examinations for a degree in Medicine at their universities in the subjects of the First Examination of the Examining Board, may enter for a part of the Final Examination at the expiration of three years from the date of passing in Anatomy and Physiology on production of the required certificates.

Members of certain recognised Indian, Colonial, and Foreign universities who have passed examinations for the Degree of Doctor or Bachelor of Medicine or Surgery in the subjects of the First Examination may present themselves for the Final Examination under special conditions. The Board also grants Diplomas in Public Health, in Psychological Medicine, in Ophthalmic Medicine and Surgery, in Tropical Medicine and Hygiene, and in Laryngology and Otology. Candidates must hold a Medical qualification registrable in the United Kingdom or be Graduates in Medicine of a recognised Indian, Colonial, or Foreign University. Particulars and conditions of admission to all examinations, fees, &c., may be obtained from the Secretary of the Examining Board, Examination Hall, Queen-square, London, W.C. 1.

ROYAL COLLEGE OF PHYSICIANS OF LONDON:

THE MEMBERSHIP AND FELLOWSHIP.

The College confers two separate diplomas—the *Fellowship*, a purely honorary distinction, and the *Membership*, obtained by examination.

Membership.—The age for admission to this diploma, it will be noticed, has been changed from 25 to 23 years. The alteration in the by-law of the College is designed to enable men who have just finished house appointments to sit for an examination for which their recent clinical experience has exactly fitted them. The candidate must either have obtained the licence of the College, or a degree of Doctor or Bachelor of Medicine at a University which is registrable by the General Medical Council and is recognised by the Censors Board. The examination is directed partly to pathology and partly to the practice of medicine. Credit is also given to candidates who show a knowledge of Latin, Greek, French, or German. Further information may be obtained from the Registrar at the College. The fee for admission as a Member of the College is 40 guineas, except when the candidate for membership is a licentiate of the College, in which case the fee already paid for the licence is deducted from the 40 guineas. The fee for the examination is 10 guineas, which is reckoned as part of the fee for admission in the case of success.

Fellowship.—The *Fellows* are selected annually from the ranks of the *Members* by the Comitia of the College.

ROYAL COLLEGE OF SURGEONS OF ENGLAND:

THE FELLOWSHIP.

The Royal College of Surgeons of England confers its diploma of Fellow upon a few distinguished persons in an honorary capacity. Two Members of long standing may also be elected to the Fellowship annually. But the bulk of the Fellows obtain the diploma as the result of examination.

Fellowship.—The examination for the Fellowship is divided into two parts—viz., the First Examination and the Second Examination. The subjects of the First Examination are Anatomy and Physiology, and those of the Second Examination are Surgery, including Surgical Anatomy and Pathology. The examinations are partly written and partly vivâ voce, and include the examination of patients and the performance of operations on the dead body. The First Examination is held in June and December and the Second Examination in May and November.

The fees for examination are: First Examination, first admission 8 guineas, and for each readmission 5 guineas. Second Examination, each admission 12 guineas. The fee payable on admission to the Fellowship by Members is 10 guineas and by non-Members 30 guineas, in addition to examination fees.

A Member of the College is admissible to the First Examination at any time after receiving his Diploma of Membership. A candidate who is not a Member is admissible after passing the First Professional Examinations of the English Conjoint Board in Anatomy and Physiology, or the equivalent examination in his University, on the production of certificates of attendance upon prescribed courses.

A Member of the College is admissible to the Second Examination at any time after having passed the First Examination, on producing evidence of having been engaged not less than six years in the study (or study and practice) of the profession.

A candidate who is not a Member of the College must possess the registrable surgical and medical degrees of universities recognised by the Council and must have been engaged in the study (or study and practice) of the profession for not less than four years subsequent to the date of obtaining the recognised qualification, one year of which shall have been spent in attendance on the Surgical Practice of a recognised hospital. The diploma of Fellow is not conferred upon successful candidates until they have attained the age of 25 years.

The Regulations may be obtained on application to the Director of Examinations, Examination Hall, Queen-square, London, W.C. 1.

SOCIETY OF APOTHECARIES OF LONDON.

The Pre-Medical and Primary examination is held quarterly. Part I. includes Chemistry, Chemical Physics; Practical Chemistry; Materia Medica and Pharmacy. Part II. includes Anatomy, Physiology, and Histology. This examination cannot be passed before the completion of twelve months' Practical Anatomy with Demonstrations, and these subjects cannot be taken separately except in the event of the candidate having previously passed in one.

The Final examination is held monthly except in September. Part I. Clinical Surgery: Principles and Practice of Surgery, Surgical Pathology, and Surgical Anatomy, Operative Manipulation, Instruments, and Appliances. Part II. Clinical Medicine: Medicine, Pharmacology, Pathology, and Morbid Histology; Forensic Medicine, Hygiene, Theory and Practice of Vaccination; and Mental Diseases. Part III. includes Midwifery, Gynæcology, and Diseases of New-born Children and the Use of Obstetric Instruments.

The course of study for the *Final examination* includes attendance on the Surgical and Medical Practice, with Post-mortem Examinations, at a hospital connected with a medical school for a period of three winter and three summer sessions, including a course of Practical Midwifery, with attendance on 20 Midwifery cases. The course of medical study must extend over five years, and the office of dresser or clinical clerk must be held at a hospital or other institution recognised by the Society. Three academic years (33 months) must elapse after a candidate has passed the examination in Anatomy and Physiology before he can complete the Final examination.

Evidence shall also be given of practical instruction in Infectious Diseases and in Mental Diseases (at a lunatic asylum or in the wards of an institution containing a special ward set apart for the treatment of mental diseases), and in any two of the following subjects: Ophthalmic Surgery, Laryngology with Rhinology and Otology, Dermatology, and Diseases of Children. Candidates intending to present themselves for examination are required to give 14 days' notice. The fee for the Licence is 20 guineas. Female candidates are admitted to examinations.

Master of Midwifery.—This diploma has now been instituted and the next examination will be on Monday, Nov. 18th, 1929. Candidates will be admitted to the examination who have been registered practitioners for at least one year, and who have held a resident appointment in an institution recognised by the Society for six months or more, and who for three months have attended an antenatal clinic and an infant welfare centre, also recognised by the Society. Until 1932 practitioners of ten years' standing may enter for the examination without further formality than the production of satisfactory evidence that they have made a special study of the subjects. The examination will be conducted by written papers and by clinical and oral tests.

The entrance fee for the examination is £10 10*s.* and a further fee, which at present is fixed at £10 10*s.*, will be paid before their admission to the Mastery, by those who have satisfied the examiners. Candidates for the examination must send in their certificates to the Secretary of the Society, Mr. Frank Haydon, who will supply any other information.

The examination offices are open from 10 A.M. to 4 P.M.; on Saturdays from 10 A.M. to 1 P.M. All letters should be addressed to the Secretary, Court of Examiners, Society of Apothecaries of London, Blackfriars, E.C. 4.

PHARMACEUTICAL SOCIETY.

THE SCHOOL OF THE PHARMACEUTICAL SOCIETY OF GREAT BRITAIN is recognised by the University of London. The Society conducts examinations for registration as (*a*) Chemist and Druggist and (*b*) Pharmaceutical Chemist

Courses of Instruction are given for the examinations in conjunction with University College.

An Intercollegiate two years' course for the Final Examination for the degree of B.Pharm. of the University of London is also given in conjunction with University College. Medical students are admitted to the lectures and laboratory work in any or all the courses. Certificates of instruction in the School are received by the Conjoint Board of the Royal Colleges and by the University of London. Graduates of approved Universities may carry out the research work necessary for the thesis for the Ph.D. of the University of London in the Society's Research Laboratories; this degree may now be taken in Pharmacognosy or Pharmacy in the Faculty of Medicine. Further information may be obtained from the Dean, Prof. Greenish, 17, Bloomsbury-square, London.

METROPOLITAN CENTRES AFFORDING POST-GRADUATE FACILITIES.

Certain organisations and institutions provide for the needs of the medical student in his cirriculum and for the post-graduate student requiring special forms of instruction and opportunities for clinical observation. Many of the institutions are recognised by the English Conjoint Examining Board as a place of study for the fifth year of the curriculum.

Special Diplomas in public health, tropical, psychological, and ophthalmic medicine, medical radiology and electrology, laryngology, otology, and tuberculosis are now granted in proof of intensive work along the different lines indicated. Of these, the Diploma in Public Health, being regulated by the General Medical Council, is registrable. Appointments to and promotion in the various Services are largely dependent on the possession of a particular diploma, and each syllabus of the special courses available at the institutions which follow, either with or without association with the Fellowship of Medicine, is planned to afford the necessary instruction.

The Special Diplomas are dealt with fully on p. 469, where the Bethlem Royal Hospital, the Maudsley Hospital, and the Diploma in Psychological Medicine are referred to. Similarly the Hospitals of the Metropolitan Asylums Board provide post-graduate as well as under-graduate facilities, while the hospitals of the Seamen's Hospital Society both supply the instruction necessary for the Diploma in Tropical Medicine and Hygiene, and coöperate in the activities of the Fellowship of Medicine and Post-Graduate Medical Association.

HOSPITALS OF THE METROPOLITAN ASYLUMS BOARD.—These hospitals, of which there are 18 in the metropolis and the near vicinity, will shortly come under the administrative powers of the London County Council. The Board hold classes of instruction in fevers at all the infectious hospitals at which ordinary medical students attend, but the only hospital to which a class of instruction for the diploma in public health is attached is the North-Eastern Hospital. This course of lectures and demonstrations (three months) on clinical practice and in hospital administration is given at the North-Eastern Hospital, St. Ann's-road, Tottenham, N. 15, by the medical superintendent, on Mondays and Wednesdays at 4.45 P.M., and alternate Saturdays at 11 A.M., beginning Thursday, Oct. 3rd, 1929. This course complies with the requirements of the revised D.P.H. regulations of the General Medical Council. Application for further information should be made to the Clerk to the Metropolitan Asylums Board, Victoria Embankment, London, E.C. 4.

SEAMEN'S HOSPITAL SOCIETY.—The Society possesses seven establishments: the Dreadnought Hospital at Greenwich, 250 beds; the Albert Dock Hospital, E. 16, 53 beds; the Hospital for Tropical Diseases, Endsleigh-gardens, W.C. 1, 56 beds; Tilbury Hospital, Tilbury Docks, Essex, 92 beds; Queen Alexandra Memorial Hospital, Marseilles, 60 beds; King George's Sanatorium for Sailors, Bramshott, Hants, 80 beds; and the Angas Home, Cudham, 36 beds. Total, 627 beds. It has also a Dispensary in the East India Dock-road from which patients are transferred to the hospitals. Courses of operative surgery and surgical pathology are arranged by the London School of Clinical Medicine at the Dreadnought Hospital.

The clinical teaching of the London School of Hygiene and Tropical Medicine is given at the Society's Hospital for Tropical Diseases, Endsleigh-gardens, W.C. 1.

THE FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.

Some 50 general and special London hospitals work in conjunction with this Association, which has its office at Room 28 in the House of the Royal Society of Medicine, 1, Wimpole-street, London, W. 1. Arrangements are made for courses in medicine and in surgery, occupying the whole or part of each day for periods of one to four weeks. Fees, £1 1*s.* to £7 7*s.* Special evening courses for the M.R.C.P. Examination are organised at intervals. Series of weekly (free) lectures (during the winter months) and clinical demonstrations in medicine and in surgery (except during August and September) are also arranged. Membership of the Fellowship is open to all qualified medical practitioners, the membership fee being 10*s.* per annum, which includes the subscription to the monthly *Post-Graduate Medical Journal.* Full information regarding the courses of study can be obtained from the Secretary.

GENERAL PRACTICE.

ROYAL NORTHERN GROUP OF HOSPITALS.—The Royal Northern Hospital, Holloway, London, N. 7, is the main institution of the Royal Northern Group of Hospitals, which includes the Royal Chest Hospital, City-road, E.C., Grovelands Hospital (Recovery Branch), Southgate, and the Reckitt Convalescent Home, Clacton-on-Sea. The total number of beds in the group is 400. Besides the honorary staff there are six anæsthetists, three pathologists, resident medical officer, resident house physician, three resident house surgeons, two resident casualty officers, and one resident obstetric surgeon. The large rectangular and circular wards, each of which contains 25 beds, the children's ward for children under 5 years of age, the observation wards in the new Casualty Department, the two operation theatres, and out-patient department are designed with a view of offering the greatest facilities for clinical work. The Special Departments include the following: Fracture, genito-urinary and neurological, physicotherapeutic, pathological (under a director of clinical pathology), tuberculosis, venereal diseases, and X ray (recently remodelled). Patients are removed to the Recovery Branch by ambulance a few days after operation. Demonstrations are given daily in the wards and out-patient departments. Clinical assistants (qualified), clinical clerks, and pathological clerks are appointed in the general and special departments and may receive certificates at the end of their terms of office. A new maternity department has been opened, and the light department has been re-equipped.

Weekly lectures by members of the hon. medical and surgical staff are free to all medical practitioners. Special classes and demonstrations are being arranged for post-graduates. They include instruction in general medicine and surgery, and also lectures and demonstrations in special subjects at the Royal Northern and Royal Chest Hospitals.

PRINCE OF WALES'S GENERAL HOSPITAL, Tottenham, N. 15.—This hospital is in the midst of a densely populated neighbourhood and contains medical, surgical, gynæcological, and children's wards, having 200 beds. There are special departments for gynæcological cases, diseases of the eye, ear, throat, and nose, skin diseases, plastic surgery, medical electricity, radiography, and dentistry. Operations are performed every afternoon of the week (except Saturday) at 2.30 P.M. Clinical instruction, ordinarily including laboratory classes, and lectures are given in the wards and out-patient departments, laboratories, and lecture hall in connexion with the North-East London Post-Graduate College attached. There are five resident medical officers, and clinical assistants are appointed under certain conditions. Special intensive post-graduate courses are also held at intervals throughout the year. Further particulars in regard to the hospital may be obtained from Dr. S. C. Shanks, Secretary to the Medical Committee, 87, Harley-street, W. 1; or from Mr. T. H. C. Benians, F.R.C.S., Dean of the College, at the Hospital.

WEST LONDON HOSPITAL, Hammersmith, W.—This hospital has 220 beds. Attached to the hospital is the West London Post-Graduate College. The practice of the hospital is reserved exclusively for qualified men. Instruction is given in the medical and surgical out-patient rooms and demonstrations are given in the wards. Clinical assistantships are obtainable in the various general and special out-patient departments. Special classes are held in Diseases of the Throat and Nose, Skin, and Eye, and in Gynæcology, Medical Electricity, Operative Surgery, Bacteriology, Anæsthetics, Intestinal Surgery, Medical and Surgical Diseases of Children, Blood and Urine, Clinical Microscopy, Cystoscopy, Venereal Diseases, and Operative Ophthalmology, Radiography, X Ray Therapy. The accommodation for post-graduates consists of a lecture room, together with reading, writing, and class rooms. The hospital has a fully equipped pathological laboratory, at which instruction is given in elementary bacteriology. The certificate of the hospital is accepted by the Admiralty, War Office, Colonial Office, and India Office in cases of study leave. Further information can be obtained on application to the Dean, Sir Henry Simson, at the Hospital. Secretary of the Post-Graduate College Mr. C. Cole, and of the Hospital Mr. H. A. Madge.

LONDON TEMPERANCE HOSPITAL, Hampstead-road, N.W. (Established 1873; Incorporated 1917.)—The hospital contains 130 beds. The medical and surgical practice of the hospital is open to students and practitioners. Operations: Monday, 1.15 P.M., Tuesday, 2.30 P.M., Wednesday, 9 A.M. and 1 P.M., Thursday, 8 A.M., Friday, 10 A.M. and 3 P.M., and Saturday, 9 A.M. New Out-patient Departments for special diseases have been opened: Neurology, Diseases of the Stomach and Disorders of Digestion, Diseases of Women, Genito-urinary Diseases, Diseases of the Rectum, and Dermatology.

HAMPSTEAD GENERAL AND NORTH-WEST LONDON HOSPITAL.—In-patient Department: Haverstock Hill, N.W.; Out-patient Department: Bayham-street, Camden Town (138 beds—viz., 109 free, 8 isolation and observation, &c., and 21 paying or contributory). Serves Hampstead and the populous districts of Kentish Town and Camden Town. The out-patients, with the exception of Hampstead casualty and emergency cases, attend exclusively at the Out-patients' Department, Bayham-street, Camden Town. Further particulars from the Secretary at the hospital. Post-graduate work is in connexion with the Fellowship of Medicine.

QUEEN MARY'S HOSPITAL, Stratford.—This hospital has developed from the West Ham and Eastern General Hospital. It has 218 beds and ministers to a very poor public. Founded as a dispensary in 1861, and developing into a hospital in 1890, steady extensions have been made during this century. A Royal Charter was obtained in 1917, and the hospital has become a valuable charity with a full medical staff of physicians and surgeons, and specialists for gynæcology, obstetrics, ophthalmological surgery, radiology, and dental surgery. The Fellowship of Medicine and Post-Graduate Medical Association makes frequent use of the opportunities here offered.

Particulars may be obtained from Major Raphael Jackson, Secretary, Queen Mary's Hospital, Stratford, E. 15.

NEUROLOGY.

THE NATIONAL HOSPITAL, QUEEN-SQUARE, W.C.—The hospital, with the Convalescent Home at East Finchley and branch at Clapham Park, contains 265 beds and cots. The out-patient physicians attend every Monday, Tuesday, Thursday, and Friday at 2 P.M., and the physicians daily. Clinical clerks are appointed under physicians and clinical assistants to out-patient physicians. Post-graduate Courses of Lectures and Demonstrations are held three times every year, usually commencing in January, May, and October, and lasting eight weeks. Special Courses in Neurological Ophthalmology, Neuropathology, and the Anatomy and Physiology of the Nervous System are given. The Pathological Laboratory is available for special work under the Pathologist.

WEST END HOSPITAL FOR NERVOUS DISEASES.—This institution is recognised by the University of London as a school of instruction in Neurology for the M.D. degree, Branch III., and for the D.P.M. The Out-patient Department is in Welbeck-street, W.; the In-patient Department is at Gloucester-gate, Regent's Park, and contains 80 beds. Completely equipped with pathological and other special departments, the hospital offers every facility for instruction in Neurological subjects. In conjunction with the Bethlem Royal Hospital, it offers courses of instruction for the D.P.M. Additional series of clinical demonstrations, apart from the general practice of the hospital, are held regularly each session, and the hospital coöperates with the Fellowship of Medicine in the programmes of special post-graduate teaching organised by the Association. Appointments as Hon. Clinical Assistants in the Out-patient Department are open to registered medical practitioners. The Savill Memorial Prize (value £15) and Medal are offered biennially for competition among post-graduate students who have attended the practice of the hospital or any special course. Full particulars may be obtained from Dr. C. C. Worster-Drought, Dean, or J. P. Wetenhall, Secretary, 73, Welbeck-street, W.

HOSPITAL FOR EPILEPSY AND PARALYSIS, &c., Maida Vale, W. (85 beds).—Both in-patient and out-patient departments of this hospital are open free to students as well as to medical graduates. The out-patient department is open every week-day except Saturday at 2 P.M.

HEART AND LUNGS.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton.—The hospital contains 350 beds. The recent provision of 25 (surgical) beds in a special block has increased the total number up to 350 (approximately). The Sanatorium at Frimley contains 100 beds and 50 beds for paying patients. Six house physicians reside in the hospital for a term of six months; their duties include attendance in the out-patient department. An additional month may be spent at the Sanatorium. Pupils are admitted to the practice of the hospital. Clinical Demonstrations are given throughout the year by members of the medical staff. Clinical assistants are appointed to the physicians in the out-patient department and clinical clerks to the physicians in the wards. The medical practice of the hospital is recognised by the English Conjoint Board and also by the University of London, the Apothecaries' Society, and the Army and Navy and Indian Medical Boards. The hospital is open to post-graduates and students. During the month previous to each conjoint examination the teaching will be as far as possible for students about to enter for the final examination. The hospital practice is open to post-graduate students.

MOUNT VERNON HOSPITAL (INCORPORATED), Northwood; **CENTRAL OUT-PATIENT DEPARTMENT**, Fitzroy-square, W.—The hospital contains 150 beds, Medical and Surgical. Clinical Demonstrations are given by the visiting Medical Staff at the hospital at Northwood. Clinical assistants are appointed to physicians in the wards and in the out-patient department.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE HEART AND LUNGS, Victoria Park, E. 2.—Special Departments: Surgical, Laryngological, Radiological, Pathological, Electrocardiographic. Assistants are appointed to the Clinics, and a limited number of research workers to the Pathological Department. The in-patient staff visit generally in the afternoon; out-patients at 2 P.M. The post-graduate students are admitted on payment of fees which entitle them to attendance at clinics, post-mortem demonstrations, and operations. Special demonstration and lecture courses are provided, and a club room. Graduates desiring Assistantships in any department should apply to the head of the Special Department, Tuberculosis Dispensary (Boroughs of Bethnal Green and part Hackney).

NATIONAL HOSPITAL FOR DISEASES OF THE HEART, Westmoreland-street, London, W. (founded 1857).—The practice of the hospital, both in the wards and out-patient department, is open daily to post-graduates and others. Systematic courses of instruction, with lectures and clinical demonstrations, are arranged during the winter and summer sessions; in addition an intensive course, of a fortnight's duration, takes place in January, July, and October of each year. The hospital is fully equipped with all the modern instruments for the investigation of the diseases of the Cardiovascular system, and facilities exist for those requiring practical instruction in Electrocardiography, X Rays, and other graphic methods. Clinical Assistants in the Out-patient Department are appointed from time to time.

DISEASES OF WOMEN AND CHILDREN.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C. 1. (contains 252 beds).—The practice is open to students of both sexes who have completed four years of medical study and also to qualified medical men and women. The medical staff are recognised by the University of London as teachers in Diseases of Children. Arrangements have also been made with University College Hospital and the London School of Medicine for Women for the routine admission of their students of both sexes to clerkships and dresserships in the wards. Appointments are made every three months to eight medical clerkships, which are open to students of the hospital. Clinical instruction is given daily by members of the visiting staff. Clinical Clerks are appointed once a month. In the pathological department facilities are afforded to post-graduates for obtaining theoretical and practical instruction in Clinical Pathology and Bacteriology, and in Medical Biochemistry in the Pathological and Biochemical Laboratories. Courses of eight to ten Lecture-Demonstrations are given at weekly intervals twice a year in both subjects (Clinical Pathology and Bacteriology, and Biochemistry.) Time spent in clerking and dressing is recognised by the Universities of London, Oxford, and Cambridge, as well as by the English Conjoint Board as part of the final curriculum. These appointments are open to students of all recognised medical schools. In addition, special lectures in post-graduate work are held throughout each term of the year, as well as routine post-graduate instruction daily.

QUEEN CHARLOTTE'S MATERNITY HOSPITAL (formerly QUEEN CHARLOTTE'S LYING-IN HOSPITAL) AND MIDWIFERY TRAINING SCHOOL, Marylebone-road, N.W.—This hospital receives over 2300 patients annually, besides having a large out-patient department. Medical pupils are received at all times of the year. Pupils have unusual opportunities of seeing obstetric complications and operative midwifery, on account of the very large number of primiparous cases—nearly one-half of the total admissions. Clinical instruction is given on the more important cases which present themselves. They also receive valuable instruction in the Antenatal Department, where over 4000 patients attend yearly. Special Lecture-demonstrations are given by members of the staff. Certificates of attendance at this hospital are recognised by all the Universities, Colleges, and licensing bodies. Pupil midwives and maternity nurses are received and specially trained. A Residential College provides accommodation for students and qualified practitioners (both men and women), and is opposite the hospital, with which it is in telephonic communication. Arrangements have been made for Medical Students to receive the preliminary instruction in Practical Midwifery recommended by the General Medical Council.

ROYAL WATERLOO HOSPITAL FOR CHILDREN AND WOMEN, Waterloo Bridge-road, S.E.—This hospital, founded at the date indicated by its title, has recently undergone considerable extensions, and has now 130 beds, while the latest buildings include a nurses' home and a new operating theatre. It has a full staff of surgeons, physicians, and gynæcologists, and also special departments. A new orthopædic department is in use, and the physiotherapeutic and electrical department has recently been extended and re-equipped. There are facilities for post-graduates to attend the general and special clinics in medicine and surgery, including a genito-urinary clinic, a clinic for varicose veins, and the X ray department of gastro-intestinal diagnosis. Particulars of post-graduate courses, which are held from time to time, can be obtained from the Secretary or from the Fellowship of Medicine.

VICTORIA HOSPITAL FOR CHILDREN, Tite-street, Chelsea, S.W.—138 beds and a large out-patient department; the home at Broadstairs has 50 beds. Private wards in the Nurses' Home, named after H.R.H. Princess Mary (Viscountess Lascelles), at 29, Tite-street, adjacent to the hospital. Patients must be under the care of a consultant of one of the hospitals of London, and the question of payment for his fees is arranged between him and the child's parents. Application for admission should be made to the Secretary.

QUEEN'S HOSPITAL FOR CHILDREN (*late North-Eastern Hospital for Children*), Hackney-road, Bethnal Green, London, E. 2.—For the sick children of the poor under 14 years of age. 134 beds in London and 30 at the seaside branch, "Little Folks" Home, Bexhill.—Special departments in Ear, Nose, Throat, Skin and Eye, and Dentistry. Rheumatic Clinic in coöperation with L.C.C. schools weekly. A radiologist attends four times weekly. There are massage and light departments, and a special whooping-cough physician. The practice of the hospital is open to students by arrangement with the medical staff, and post-graduate instruction in children's diseases, lectures and demonstrations are given at times notified by the Fellowship of Medicine.

PADDINGTON GREEN CHILDREN'S HOSPITAL (42 beds).—This is a small hospital with a large out-patient department and a full staff, with eye, ear, skin, and dental departments. The facilities which it offers for observation of clinical practice are used by the Fellowship of Medicine.

HOSPITAL FOR WOMEN, Soho-square, W. (80 beds).—The teaching is available for post-graduates only, in limited numbers. Operations take place daily at 2 o'clock except on Saturdays. The X ray department is supplied with the latest installation both for diagnosis and treatment, and experience can also be gained in the treatment of malignant disease by means of radium. Incorporated is the London School of Gynæcology, comprising attendance in out-patient department, operating theatre, clinical lectures, and X ray treatment.

SAMARITAN FREE HOSPITAL FOR WOMEN, Marylebone-road, N.W. (70 beds).—Qualified practitioners are admitted as clinical assistants to both the in- and out-patient departments. Full particulars may be obtained from the Secretary to the Medical Committee at the hospital.

EAST LONDON HOSPITAL FOR CHILDREN AND DISPENSARY FOR WOMEN, Glamis-road, Shadwell, E. (136 cots).—Clinical instruction is given by the physicians and surgeons to the hospital to students in the fifth year of the curriculum. Two clinical clerkships for qualified or unqualified students are open every three months subject to reappointment if desired. Clinical assistants (qualified men only) are from time to time appointed in the out-patient department. Any additional information may be obtained on applying to the Secretary.

CHELSEA HOSPITAL FOR WOMEN, Arthur-street, Chelsea, S.W. 3.—This hospital has 100 beds, and a certain number are reserved for patients paying £5 5s. a week and small fees to the surgeons for operations. There is a convalescent home of 32 beds at St. Leonards. At a large out-patient department the patients are seen at a nominal payment.

THE EVELINA HOSPITAL, Southwark (76 cots), and THE BELGRAVE HOSPITAL (70 cots), Clapham-road, also give facilities for out-patient practice.

OPHTHALMOLOGY.

ROYAL LONDON OPHTHALMIC HOSPITAL (Moorfields, 1804-1899), City-road, E.C. (188 beds).—The attendance at Moorfields Eye Hospital is now very large. Operations are performed daily from 10 A.M. to 1 P.M., and four surgeons attend on each day. Students are admitted to the practice of the hospital, and special courses of instruction are given, which extend over a period of five months, by members of the Surgical Staff, beginning in October and March. The instruction and classes are arranged so as to meet the requirements for the various diplomas in Ophthalmology, both the preliminary examination in Anatomy, Physiology and Optics, and those subjects required in the second part. Students of the hospital are eligible as house surgeons or clinical and junior assistants; these are appointed every three months.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL, Broad-street, Holborn, W.C. (85 beds, including 14 rooms for paying patients).—This hospital has recently removed from its original site at Charing Cross to much larger premises, well adapted for teaching purposes. The clinics are held in the afternoons from 1 P.M. Operations are performed daily in the theatre at 3 P.M. Lectures and practical classes in the various branches of Ophthalmology, including Operative Surgery, Bacteriology, and Pathology, are held during the winter and summer sessions at 5 P.M. The practice of the hospital is open to both men and women practitioners, and medical students. Post-graduate students at the hospital are eligible for appointment as house surgeon, assistant house surgeon, refraction assistant (six appointments paid), and senior and junior clinical assistants.

ROYAL EYE HOSPITAL, St. George's-circus, Southwark, S.E.—There are 44 beds and 2 cots. Clinical instruction is given to students and post-graduates daily at 2.30 P.M., and Lectures, Demonstrations, and Laboratory Classes are arranged in preparation for examinations in Ophthalmology. Apparatus has been installed for the Microscopy of the Living Eye. Post-graduate students are eligible for appointment as Clinical Assistants and as Refraction Officers.

CENTRAL LONDON OPHTHALMIC HOSPITAL, Judd-street, St. Pancras, W.C.—This hospital has 40 beds, and clinical teaching is given daily. Classes of instruction in the use of the ophthalmoscope, with demonstrations on cases, and also classes on other subjects, to meet the requirements of the Conjoint Board for the D.O.M.S., and of the University of London for the M.S. in Ophthalmology, are given during the winter months, commencing in October. This school is recognised as a teaching institution by the Universities of London and Oxford, as well as the English Conjoint Board. It receives a portion of the pupils of the University College Hospital for the purposes of ophthalmic training. The Pathological and Bacteriological Laboratories have been rendered available for the use of any ophthalmic surgeons who desire to send specimens for examination. A small fee is charged for a report. A Clinical Demonstration is held by members of the staff at the Central London Ophthalmic Hospital at 5 P.M. on the first Tuesday of every month. Students of medicine and doctors are admitted free.

GENITO-URINARY AND VENEREAL DISEASES.

LONDON LOCK HOSPITAL AND HOME. (Founded 1746.)—In the institution at Harrow-road, W., there are 202 beds. In the male department and out-patient department in Dean-street, Soho, W., there are 38 beds. Male and female patients are seen at 91, Dean-street, Oxford-street, W.1, at any time from 9 A.M. until 9 P.M. daily, including Sundays. Intravenous injections are given at every clinic. Irrigations for males are given daily from 8 A.M. to 9 P.M. Female patients and children are seen daily at 283, Harrow-road, Paddington, W.9, from 9 A.M. until 8 P.M. Irrigations for females are given at any time. The hospital is linked up with the Fellowship of Medicine; special courses of lectures are held in May and November each year, and application for tickets should be made direct to the Secretary of the Fellowship. Only a limited number of practitioners and students are permitted to attend the practice of the Female Lock Hospital, and application should be made to the Dean at the Male Lock Hospital, between the hours of 11 A.M. and 5 P.M., or to the Secretary at the Head office.

ST. MARK'S HOSPITAL FOR CANCER, FISTULA, AND OTHER DISEASES OF THE RECTUM, City-road, E.C.1. (Founded 1835.) (62 general beds and 10 private beds.)—For men and women. Operations are performed on Mondays, Wednesdays, and Thursdays at 2.30 P.M. Medical practitioners and students are invited to the operations and to the clinical instruction in the wards and in the out-patient department. Two fortnightly courses held during year in coöperation with the Fellowship of Medicine.

St. Peter's Hospital for Stone and other Urinary Diseases, Henrietta-street, Covent Garden. (Established 1860.) (30 beds for men and 2 beds for women and children).—The X ray department is diagnostic only. A loan of radium salts for research work was made by the British Empire Cancer Campaign in 1925. Medical practitioners and students are invited to the clinical instructions which are given in the wards and out-patient department daily, excepting that the only out-patient clinic open to medical women is that held at 2 P.M. Fridays for women and children, and to the operations in the theatre on Mondays at 2.30 P.M., and Wednesdays and Fridays at 2 P.M. Post-graduate Courses of Lectures are given from time to time, dates being advertised in the medical journals.

All Saints' Hospital for Genito-Urinary Diseases.—The in-patient department (30 beds) is at Finchley-road, and the terms of admission are free or by payment according to means. The out-patient department in the Vauxhall Bridge-road provides clinical instruction through the Fellowship of Medicine, in addition to which demonstrations in cystoscopy and other branches of genito-urinary work are available for all medical practitioners at the Out-patient Department on Wednesday, Thursday, and Saturday afternoons, at 1.30 P.M., without fee.

ORTHOPÆDICS.

Royal National Orthopædic Hospital, Great Portland-street, W. (450 beds.)—This institution is a good example of the fusion of small and scattered activities for the creation of an effective whole. The three orthopædic hospitals of the metropolis were combined for the formation of this central institution at the instance of the King's Hospital Fund, with the result that the grants from this Fund and the income from subscriptions can now be used to far better purpose and with economy. The hospital has also been approved by the Ministry of Health for the treatment of tuberculosis, the connexion between orthopædics and the therapeutics required in many forms of tuberculosis having become obvious. Country branch at Brockley Hill, Stanmore. (214 beds). Both branches of the hospital are residential schools for physically defective children, certified by the Board of Education. Post-graduate courses of 14 days each are held twice yearly.

EAR, NOSE, AND THROAT.

Central London Throat, Nose, and Ear Hospital, Gray's Inn-road, W.C.—The hospital is open daily to all qualified medical practitioners on presentation of their visiting cards. Demonstrations of the cases and clinical instruction are given daily by the chief surgeon of each clinic. Lectures each Friday at 4 P.M. An intensive Course of Lectures (especially suitable to D.L.O. students), with Operative Surgery Class, Peroral Endoscopy Class, and Pathology Class is given twice yearly—in May and October. Preparatory courses in Methods of Examination and Diagnosis at frequent intervals. Consultations on interesting cases take place on the fourth Wednesday in each month at 4 P.M. Clinical Assistants are appointed and are expected to hold office for at least three months. They are required to attend twice weekly at 1.30 o'clock for the afternoon, and at 4.30 o'clock for the evening clinics. New wing, with complete out-patient department and additional wards, was opened in August last.

Golden-square Throat, Nose and Ear Hospital (with which is amalgamated the London Throat Hospital, Great Portland-street).—Clinical instruction in the diagnosis and treatment of disease is given daily in the out-patient department from 2 to 5 P.M., and on Tuesdays and Fridays from 6.30 to 9 P.M. There is an annual out-patient attendance of over 55,000. Minor operations are performed on Mondays, Wednesdays, and Fridays, at 9.30 A.M. New wards and in-patient operating theatres have been opened recently, and the hospital now contains 95 beds. Practitioners and medical students are admitted to the practice of the hospital, and clinical assistants are appointed periodically.

Metropolitan Ear, Nose, and Throat Hospital. (Founded 1838.)—The hospital is in Fitzroy-square, W. The Out-patient Department is opened daily (Saturdays excepted) at 2.30 P.M. to all medical practitioners and senior students for acquiring clinical instruction and technical knowledge. Operations upon in-patients are performed on Tuesdays, Wednesdays, and Thursdays at 10 A.M. Clinical Assistants are appointed as vacancies occur.

SKIN.

London School of Dermatology, St. John's Hospital for Diseases of the Skin, 49, Leicester-square, W.C.—In-patient Department (33 beds) at 262, Uxbridge-road, W. Out-patient Clinics are held daily at 2 and 6 P.M. (Saturdays 2 P.M. only), when demonstrations are given on the cases presenting themselves. The Chesterfield Lectures, constituting a systematic course in dermatology, are given on Tuesdays and Thursdays at 5 P.M., from October to March, by the hon. medical staff of St. John's Hospital and the physicians in charge of the Dermatological Departments of the London Teaching Hospitals. The lectures are free to those attending the practice of the hospital and to registered medical students. At the end of the course an examination is held for the Chesterfield Medal in Dermatology, and is open to those who have attended three-quarters of the lectures. The Electrical Department is open daily from 2 to 4 P.M., except on Wednesdays and Saturdays. Laboratory Courses in the Pathology and Bacteriology of the Skin can be arranged.

The London Skin Hospital (Fitzroy-square), and the Hospital for Diseases of the Skin (Blackfriars-road), admit students to their practice, which is among out-patients, daily at 2.30.

CENTRES OUTSIDE LONDON AFFORDING EDUCATIONAL FACILITIES.

Nearly every hospital of a general character in the country having more than 150 beds falls within this category, and certain of them have already been noticed in connexion with the universities to which their clinical practice is attached. The hospitals vary much in size and scope.

The following alphabetical list includes the provincial hospitals which are recognised by the English Conjoint Board for a part of the required training in medical and surgical practice through clerkships and dresserships.

Bath Royal United Hospital, Bath.—This hospital contains 212 beds, 72 of which are situated in Combe Park, Bath, and are for *paying patients* only, and possesses X Ray, Massage, Bacteriological Departments, a Pathological Laboratory, and a fine library. Secretary: Mr. J. M. Sheppard. V.D. Clinics are held on Tuesdays (for women), and on Fridays and Saturdays (for men), at 5 P.M., and Ear, Throat, and Nose Clinics on Thursdays, at 4 P.M.

Bedford County Hospital, Bedford.—This hospital has 124 beds, including 15 beds in the paying and 13 beds in the maternity wards, X Ray and Pathological Departments. There is in connexion with the institution a convalescent home (20 beds) at Aspley Heath, nr. Woburn Sands. The hospital is approved by the University of London for the M.D. and M.S. Examinations. Secretary: Mr. Beauchamp Wadmore.

Bradford Royal Infirmary, Bradford.—This hospital contains 215 beds and, in addition, has 50 recovery beds at the Woodlands Convalescent Home, Rawdon. There are 4 Honorary Consulting Physicians, 1 Honorary Consulting Surgeon, 1 Honorary Consulting Laryngologist, 1 Honorary Consulting Gynæcologist, 1 Honorary Consulting Pathologist, and

1 Honorary Consulting Dental Surgeon. The Acting Staff consists of 4 Honorary Physicians, 4 Honorary Surgeons, 1 Honorary Radiologist, 1 Honorary Laryngologist, 1 Honorary Ophthalmic Surgeon, 1 Honorary Dental Surgeon, 1 Honorary Assistant Physician, 2 Honorary Assistant Surgeons, 1 Honorary Assistant Radiologist, 5 Anæsthetists, 1 Pathologist, 1 Physician in charge of Radium Therapy Department, 1 Resident Surgical Officer, 1 House Physician, and 4 House Surgeons. There are special clinics for Orthopædic cases, for Electrotherapeutic and Sunlight Treatment, and for Radium Therapy. A new hospital of 360 beds with a self-contained block for 70 paying patients is in construction. Secretary-Superintendent: Mr. J. J. Barron.

COVENTRY AND WARWICKSHIRE HOSPITAL, Coventry (established 1840).—There are 307 beds available at the Main Hospital, and 40 beds at the Alcock Convalescent Hospital, Keresley (three and a half miles distance), which is used as an annexe. At the Main Hospital there are separate Medical, Surgical, Maternity, Children's and Accident Wards, also separate Ophthalmic Block complete with its own Theatre. There are separate departments for Clinics for Ear, Nose and Throat Diseases, X Ray, Electrical, and Sunlight Clinics, also V.D. Clinic. There is also an up-to-date Pathological Laboratory.

DERBYSHIRE ROYAL INFIRMARY, Derby.—This general hospital of 338 beds was rebuilt in 1892–94. In recent years there have been numerous alterations and additions to keep pace with modern requirements. The hospital is built on the pavilion system and provides, in addition to the usual Medical and Surgical blocks, a separate Ophthalmic block of 40 beds, a separate Children's block of 34 beds (Medical and Surgical), Gynæcological Wards, and an Ear, Throat, and Nose Department. There is a large and well-equipped Out-patient Department, also separate Orthopædic, X Ray, Electrical, Pathological, and Venereal Diseases Departments. The Honorary Visiting Staff consists of 2 Honorary Physicians, 3 Honorary Surgeons, 1 Honorary Ophthalmic Surgeon, 1 Honorary Gynæcologist, 1 Honorary Assistant, Physician, 1 Honorary Assistant Surgeon, 1 Honorary Assistant Ophthalmic Surgeon, 1 Honorary Pathologist, and 2 Honorary Surgeon Dentists. The salaried Medical Staff consists of a non-Resident Staff of 1 Surgeon-in-charge of X Ray and Electrical Departments, 1 Surgeon-in-charge of Venereal Diseases Department, 4 Anæsthetists, and a Resident Staff of 4 House Surgeons, 1 House Physician, and 1 Assistant House Surgeon and Casualty Officer. Registered Medical Students are admitted to witness the medical and surgical practice on payment of fees. Superintendent and Secretary: Mr. Walter Banks, F.C.I.S.

GLOUCESTERSHIRE ROYAL INFIRMARY AND EYE INSTITUTION, Gloucester.—This hospital has 145 beds. Secretary: F. J. Symons. An Electrical and Massage department has been established and Venereal Clinic opened. Also Ear, Nose, and Throat department, X Ray department, Ultra-violet Ray department, Orthopædic department, Dental department, and Pathological Laboratory.

HULL ROYAL INFIRMARY, Hull.—This hospital contains 272 beds, and since its establishment in 1782 has undergone steady additions and improvements, including up-to-date Ophthalmic, Radiological Nose, Throat and Ear, Dental, V.D., Violet Rays and Pathological Departments. Recent extensions include a new Operating Theatre, Nurses' Home, and extensions to the old X Ray, Electrical, and Out-patient Departments. Work is in progress on the erection of a new 500-bed hospital at Sutton-on-Hull. The Staff consists of 2 Consulting Physicians, 3 Consulting Surgeons, 2 Consulting Ophthalmic Surgeons, 3 Physicians, 4 Surgeons, 1 Ophthalmic Surgeon, 1 Aural Surgeon, 2 Radiologists, 1 Pathologist, 2 Assistant Physicians, 2 Assistant Surgeons, 1 Assistant Ophthalmic Surgeon, 1 Assistant Aural Surgeon, 1 Dental Surgeon, 1 Assistant Dental Surgeon, 4 Anæsthetists, 1 Officer-in-charge of V.D. Department. Resident Staff: 1 House Physician, 1 House Surgeon, 1 Assistant House Physician, 2 Assistant House Surgeons, 1 Assistant Surgeon to Special Departments, 1 Casualty Officer. An annexe at Withernsea has accommodation for 30 patients.

KENT AND CANTERBURY GENERAL HOSPITAL, Canterbury.—The hospital contains 120 beds. Pupils of the staff are admitted to the practice of the hospital. Operations daily. Special departments include Ophthalmic, Ear, Nose and Throat, Venereal, Orthopædic, Electrical, Actinotherapeutic, X Ray, and Bacteriological. Secretary: Mr. W. T. Southwood.

LEICESTER ROYAL INFIRMARY, Leicester.—At the General Infirmary there are 333 beds, and at the Children's Hospital in connexion, 70; venereal diseases, 17; total 420 beds. A reconstruction scheme has been carried out, and £250,000 spent on bringing the accommodation of the institution to a modern standard of efficiency. This scheme has included the provision of two modern operating theatres, two new wings, and self-contained out-patients' department. The Children's Hospital has been reconstructed and enlarged by the addition of a third ward at a cost of £14,500. Pathological Laboratories and post-mortem rooms were erected at a cost of £11,000, also an orthopædic out-patient department at a cost of £9500, £5000 of which was provided by the Freemasons of the province as their war memorial. The Nurses' Home has recently undergone enlargement by 60 bedrooms, and now provides for 160 nurses and staff. An old central wing is being replaced by a new wing of three wards, and other structural improvements comprise reconstruction of the kitchens, new temporary ward of 30 beds, and a new venereal disease department. There are eleven resident salaried medical officers—viz., four house surgeons, two house physicians, three anæsthetists, and two dressers. Most of the posts are filled half-yearly and afford exceptional opportunities for post-graduate experience and senior students. Dressers are given an honorarium. Students who seek resident Dresserships should apply to the House Governor and Secretary. A post-graduate course of lectures is arranged annually by the Leicester Medical Association, and also clinical classes are held for graduates preparing for M.D. and M.R.C.P.

NORFOLK AND NORWICH HOSPITAL, Norwich.—This hospital has at present 350 beds. There is a convalescent home with accommodation for 35 patients at Cromer. The Honorary Medical and Surgical Staff consist of 2 Consulting Physicians, 3 Consulting Surgeons, 1 Consulting Radiologist, 1 Consulting Ear, Nose and Throat Surgeon, 3 Physicians, 3 Surgeons, 1 Assistant Physician, 3 Assistant Surgeons, 1 Surgeon, Ear, Nose and Throat Department; 2 Ophthalmic Surgeons, 1 Radiologist, 1 Pathologist, and 2 Dental Surgeons. There are 3 Honorary Anæsthetists and Honorary Assistants to the Ear, Nose and Throat Department, the X Ray Department, Ophthalmic Department, and Cardio-Vascular Clinic. Other medical officers are: 1 Assistant Pathologist and 1 Assistant to the Venereal Diseases Department. The Resident Medical Staff consists of 1 House Physician, 3 House Surgeons, 1 House Surgeon to the Ear, Nose, Throat, and Eye Department, and 1 Casualty Officer. A private patients' home has recently been opened. Students are admitted to the practice of the Hospital for a fee of £5 5s. for six months. House Governor and Secretary: Mr. Frank Inch.

NORTHAMPTON GENERAL HOSPITAL, Northampton.—Two new wings were opened in 1904 and the old buildings entirely renovated and rearranged. In 1926 a new isolation block of 30 beds was opened. The number of beds is 230. There is an up-to-date Pathological Laboratory; also, X Ray and Therapeutic Department and V.D. Clinic. Two new operating theatres are being built.

II.—SCOTLAND.

THE UNIVERSITIES.

UNIVERSITY OF EDINBURGH.

Four Degrees in Medicine and Surgery are conferred by the University of Edinburgh—viz., *M.B.*, *Ch.B.*, *M.D.*, and *Ch.M.* The degree of *Ch.B.* shall not be conferred on any person who does not at the same time obtain the degree of *M.B.*, and the degree of *M.B.* shall not be conferred on any person who does not at the same time obtain the degree of *Ch.B.* No one is admitted to the degrees who has not been engaged in study for five years.

Candidates for the degrees of M.B. and Ch.B. must have attended for at least three academic years the medical and surgical practice either of the Royal Infirmary, Edinburgh, or of a general hospital elsewhere which accommodates not fewer than 80 patients and possesses a distinct staff of physicians and surgeons. They must have attended courses of instruction in Clinical Surgery and Clinical Medicine each of nine months, and courses of instruction in all the subsidiary subjects. They must have attended a course in Clinical and Practical Midwifery and have personally conducted 12 cases.

With respect to the places and institutions at which the studies of the candidate may be prosecuted the following regulations have effect:—Three of the five years of medical study must be spent in the University of Edinburgh. The remaining two years may be spent in any University of the United Kingdom, or in any Indian, Colonial, or Foreign University or medical school recognised for the purpose by the University Court.

Women are admitted to graduation in medicine under the same conditions as men.

Bachelors of Medicine and *Bachelors of Surgery* may proceed to the degrees of *Doctor of Medicine* and *Master of Surgery* after they have spent one year in the medical or surgical wards respectively of a hospital, or the Military or Naval Medical Services, or in scientific work bearing directly on their profession, or two years in practice. In each case an examination must be passed and a thesis submitted.

Post-graduate Instruction.—The University takes part in the Courses given under the auspices of the Edinburgh Post-graduate Courses in Medicine. In the departments of the Faculty of Medicine provision is made for research by students of graduate standing. In the University laboratories facilities will be provided for approved candidates for the Degree of Ph.D.

In connexion with the University and Royal Colleges Post-graduate Instruction is given each year, chiefly in the Summer Vacation (July–September). Special Courses are arranged for, and particulars may be had on application to the Hon. Secretary, Post-graduate Courses in Medicine.

The University of Edinburgh is especially rich in scholarships and prizes in medical subjects. Full particulars concerning these, as well as concerning the fees at different stages, can be obtained from the Dean of the Medical Faculty.

ROYAL INFIRMARY, Edinburgh.—1000 beds, including 42 cots for children. The clinical work of the Edinburgh student is done at the Royal Infirmary. Courses of Clinical Medicine and Surgery are given by the physicians and surgeons to male and female students. Special instruction is given on Diseases of Women, Physical Diagnosis, Diseases of the Skin, Diseases of the Eye, the Ear, the Larynx, and the Teeth. Separate wards are devoted to Venereal Diseases, Diseases of Women, Diseases of the Eye, the Ear, Throat and Nose, and the Skin, and also to cases of Incidental Delirium or Insanity. There is also a large and complete Radiological Department. Post-mortem examinations are conducted in the anatomical theatre by the pathologist and his assistants, who also give practical instruction in Pathological Anatomy and Histology.

The appointments are: 1. Resident physicians and surgeons are appointed and live in the house free of charge. The appointment is for six months, but may be renewed at the end of that period by special recommendation. 2. Non-resident house physicians and surgeons and clinical assistants are appointed for six months. The appointment may be renewed for a like period by special recommendation. 3. Clerks and dressers are appointed by the physicians and surgeons. These appointments are open to all students and junior practitioners holding hospital tickets. 4. Assistants in the Pathological Department.

Facilities are given in connexion with the Post-graduate Courses arranged by the Edinburgh University and the two Royal Colleges jointly.

ROYAL HOSPITAL FOR SICK CHILDREN, Sciennes-road, Edinburgh.—120 beds, and fitted with every modern improvement. A fully equipped out-patient department (medical and surgical) is conducted daily. Systematic courses of instruction, which qualify for graduation in the Edinburgh University and elsewhere, are given thrice throughout the year by the staff. Each course consists of 50 meetings and combines medicine and surgery. Post-graduate Courses of Lectures are held during the summer vacation. Full particulars with regard to teaching can be obtained from the Dean's office, University New Buildings, Edinburgh.

EYE, EAR, AND THROAT INFIRMARY OF EDINBURGH (with which is incorporated the Edinburgh Eye Dispensary), 6, Cambridge-street, Lothian-road.—Clinical Lectures and Instruction are given in this institution, which is open at 1 o'clock daily for outdoor patients for Eye Diseases; Mondays, Thursdays, and Saturdays at 12 noon, and Tuesdays and Fridays at 4 P.M. for outdoor Ear, Nose, and Throat Patients. Patients whose diseases require operations or extra care are accommodated in the house (10 beds). Practical Ophthalmoscopic Classes may be arranged, and Clinical Assistants are appointed from time to time. A Post-graduate Course in Diseases of the Ear, Nose, and Throat is held each academic term, commencing in May, October and January, and continuing for six weeks. The next course commences in October. The class meets at 5 P.M. on Tuesdays and Fridays, and the instruction, which is practical, is supplemented by lantern demonstrations. Full particulars from the Secretary, 82, Charlotte-square.

UNIVERSITY OF GLASGOW.

The University of Glasgow is both a teaching and a degree-granting body, but admits to graduation only candidates whose preliminary examination and course of study conform to its own regulations. Within certain limits instruction given by recognised medical schools and teachers may be accepted, but not less than one-half of the subjects other than clinical must be taken in this or some other recognised university, and at least two years of the course must be taken in Glasgow University. Seven degrees, open both to men and women, are conferred: *M.B.* and *Ch.B.* (always conjointly), *M.D.* and *Ch.M.*; *B.Sc.* in Public Health; *D.Sc.* in Public Health; *B.Sc.* in Pharmacy; and *Ph.D.* in the Faculty of Medicine. A Diploma in Public Health (*D.P.H.*) is also granted.

All information as regards the extent and standard of the Preliminary Examination may be obtained by application to the Secretary, Scottish Universities Entrance Board, 81, North-street, St. Andrews.

For the degrees of M.B. and Ch.B. a curriculum of five years is required. The candidate must attend a course or courses of instruction in each of the following subjects of study, extending over not less than the number of terms specified in each case, and including such class examinations as may be prescribed in connexion with the several courses:—Chemistry (including Organic Chemistry), with Practical Chemistry, three terms; Physics (with practical work), one term; Botany (with practical work), one term; Zoology (with practical work), one term; Anatomy and Practical Anatomy, five terms; Physiology and

Practical Physiology, three terms; Materia Medica and Therapeutics (together or separately), each subject, one term; Pathology and Practical Pathology, three terms; Medical Jurisprudence and Public Health (together or separately), each subject, one term; Midwifery and Diseases peculiar to Women and to Infants, two terms; Surgery, two terms; Medicine, two terms. Candidates must attend for at least three years the Medical and Surgical Practice of a recognised hospital accommodating at least 80 patients and having a distinct staff of physicians and surgeons. At least nine months' hospital attendance is required on both Clinical Surgery and Clinical Medicine with nine months more of general hospital practice; the student must have acted for six months as clerk in medical and dresser in surgical wards, and must have had six months' outdoor practice; he must also have attended a course of Mental Diseases and of Practical Pharmacy (25 meetings), must have been properly instructed in Vaccination at a public vaccination station, and must have attended at least 20 cases of labour and the Practice of a Lying-in Hospital. The University also requires further study in various special subjects:. Ophthalmology, Diseases of the Ear, Diseases of the Throat and Nose, Venereal Diseases, Tuberculosis, Fevers, Vaccination. The final year consists of three intensive terms of study: one devoted to Midwifery and Diseases of Women, one to Surgery, and one to Medicine.

There are four Professional Examinations, the first comprising Botany, Zoology, Physics, and Chemistry; the second comprising Anatomy and Physiology; the third comprising Materia Medica and Therapeutics and Pathology; and the fourth or final, comprising Medical Jurisprudence and Public Health, Surgery and Clinical Surgery, Practice of Medicine and Clinical Medicine, and Midwifery and the Diseases Peculiar to Women and to Infants.

The degrees of M.D. (Doctor of Medicine) and Ch.M. (Master of Surgery) are granted to candidates, not under 24 years of age, who have previously obtained the double bachelorship on completing examinations, in Clinical Medicine for M.D. and in Surgical Anatomy, operations on the dead body, and Clinical Surgery for Ch.M. The higher degree of Doctor of Philosophy (Ph.D.) is also conferred in the Faculty of Medicine. Candidates must already have obtained a degree (or equivalent diploma) from an approved University or College and must prosecute a course of special study or research for two or three years and given evidence of satisfactory progress. A thesis must be presented for approval by the Senate on the recommendation of a Special Committee. The candidate may be required to undergo an oral or other examination on the subject matter of the thesis.

Post-graduate Medical Teaching is available under the auspices of Glasgow Post-Graduate Medical Association, which is representative of practically all the Teaching Institutions in Glasgow. Weekly demonstrations for practitioners are given throughout the winter and spring, and comprehensive courses of instruction during the summer and autumn. There is a General Medical and Surgical Course during the last two weeks of August and the first two weeks of September. This is a whole-time course and includes most of the subjects of interest to the general practitioner. The forenoons are occupied with General Medicine and Surgical Diagnosis and Minor Surgery in the Royal Infirmary and in the Victoria Infirmary. In the afternoons special subjects are dealt with in some of the special hospitals or in the special departments of the general hospitals—two subjects each afternoon. On the four Saturday forenoons Tuberculosis and Infectious Fevers are demonstrated at Ruchill Fever Hospital. Arrangements have also been made whereby a limited number of graduates may become attached to wards or out-patient departments nominally as clinical assistants for definite periods throughout the year. As such they work under the direct supervision of the physician or surgeon in charge, and carry out such detailed investigations as directed. Further information may be obtained from the Secretary of the Association, 9, Woodside-terrace, Glasgow.

There are many Bursaries, Scholarships, and Prizes in connexion with the Medical Course.

ROYAL INFIRMARY, Glasgow.—The ancient connexion between the University of Glasgow and the Royal Infirmary was revived in 1911, when four University Chairs and several University Lectureships were established at the infirmary. New Lectureships in Materia Medica and Pathological Biochemistry were established recently, and this year a lectureship in Bacteriology has been founded. St. Mungo's College which embraces and continues the original Royal Infirmary Medical School, is situated in the infirmary grounds. The infirmary has, including the Ophthalmic Department, over 800 beds. In addition to the large medical and surgical departments, there are special wards for diseases of women, of the throat, nose, and ear, skin, eye, burns, septic cases, and biochemical investigation. The wards are open to Women Students. Six house physicians and nine house surgeons, who board in the hospital free of charge, are appointed every six months; also five non-resident house physicians, eight non-resident house surgeons, and one non-resident dental house surgeon. Clerks and dressers are appointed by the physicians and surgeons. As a large number of cases of acute diseases and accidents of a varied character are received, these appointments are very valuable and desirable. There is a modern and fully equipped Electrical Pavilion and Massage Department, and year by year the latest and most approved apparatus for diagnosis and treatment has been added. Post-graduate Classes are held during August and September in Clinical Medicine, Clinical Surgery, Clinical Gynæcology, Diseases of the Skin, Biochemistry, Diseases of the Throat, Nose and Ear, and in Diseases of the Eye. Tutorial Classes for senior students are also held in August and September.

For information regarding fees and other particulars, application should be made to the Superintendent.

GLASGOW WESTERN INFIRMARY.—This hospital of 600 beds adjoins the University. Special wards are set apart for Diseases of Women, Throat, Nose, and Ear, and for Affections of the Skin. In the out-patient department there are special clinics for Diseases of Women and for Diseases of the Throat, Ear, Teeth, Skin, Venereal Disease, and Electrotherapeutics. The Clinical Courses are given by the physicians and surgeons, each of whom conducts a separate class, and students require to enter their names at the beginning of the session for the class which they propose to attend. Special instruction is given to junior students by tutors or assistants, and clinical clerks and dressers are selected from the members of the class. All the courses of clinical instruction are recognised by the University of Glasgow and the other boards in the kingdom. In the Pathological and Bacteriological Departments the courses are both systematic and practical, and extend through the winter and following summer; these are likewise recognised by the University for graduation. In addition Post-graduate Courses are held. Eighteen resident assistants are appointed annually, without salary, from those who have completed their course. In the Clinical Laboratory students receive laboratory instruction from the lecturer on clinical methods. A School of Massage, Medical Electricity, and Swedish Remedial Exercises has been established to qualify for the Certificate of the Chartered Society of Massage and Medical Gymnastics. Secretary: J. Matheson Johnston, C.A.

VICTORIA INFIRMARY, 67, Carlton-place, Glasgow.—This institution, which has 380 beds, is the third of the extensive general hospitals in Glasgow to afford opportunity for clinical instruction to students. In addition to a full general staff there is a clinical research laboratory with pathologists and bacteriologists attached, radiological instructor, and a full assortment of specialists. The Bellahouston

Dispensary, also with a clinical staff, is conducted in connexion with the Victoria Infirmary. For further particulars of the clinical practice application should be made to the Secretary and Treasurer.

The Anderson College of Medicine, Dumbarton-road, Glasgow, W.1.—Courses are given which qualify for all the licensing boards and for the Universities of Oxford, Cambridge, London, Durham, Edinburgh, and Glasgow (the latter two under certain conditions). Extensive accommodation is provided for Practical Anatomy, Practical Chemistry, Practical Botany, Practical Zoology, Practical Physiology, Practical Pharmacy, Operative Surgery, and Public Health. Ample provision has also been made for the comfort *of students. Women students are admitted on the* same terms as men, and the Carnegie Trust extends its benefactions to students of the College. (Full particulars may be obtained from the Carnegie Trust Offices, Merchants' Hall, Edinburgh.)

Candidates for the L.D.S. can obtain the full medical curriculum in Anatomy, Chemistry, Physiology, Surgery, Practice of Medicine, and Materia Medica. The courses special to Dentistry are conducted at the Dental Hospital, Glasgow.

Communications relating to the College to be addressed to the Secretary of the Medical Faculty, Communications relating to the Preliminary Examination in General Education to be addressed to the Educational Institute Office, 47, Moray-place, Edinburgh; and relating to the Triple Qualification and to the Dental Qualification to be addressed to Royal Faculty Hall, 242, St. Vincent-street, Glasgow.

Queen Margaret College (Women's Department of the University).—This is an integral part of the University of Glasgow. The classes are taught by professors of the University and other lecturers appointed by the University Court, and it is governed by the University Court and Senate. The curricula, regulations, and fees are the same as those of the male students, and the University degrees are open to women on the same conditions as to men. The school of medicine is a special feature of the College, and gives full preparation for the medical degrees of the University. The women students attend classes in the various University Buildings at Gilmorehill and Queen Margaret College, the Royal Infirmary, the Western Infirmary, and the Victoria Infirmary. Facilities for clinical work are given in the Royal, Western and Victoria Infirmaries, in the Maternity, Royal Sick Children's, and other hospitals. The Arthur Scholarship is open every third year to students of first year; other Bursaries are open in Arts and Medicine, and women are admitted to certain University bursaries and fellowships.

St. Mungo's College and Glasgow Royal Infirmary.—*The classes in St. Mungo's College* qualify for the medical qualifications of the English, Scotch, and Irish Conjoint Boards, for the dental diplomas of the English, Irish, and Scottish Boards and, under certain conditions, for the various universities, including the University of London. Students who have fulfilled the conditions of the Carnegie Trust are eligible for the benefits of this Trust during the whole course of their studies at St. Mungo's College.

Further particulars can be obtained from the Secretary of the Medical Faculty.

Royal Hospital for Sick Children, St. Vincent-street, Glasgow.—This institution consists of: (1) a hospital at Yorkhill containing 275 cots, built on an elevated and central site close to the University, and opened in July, 1914; (2) a Dispensary, or Out-patient Department, in West Graham-street, opened in October, 1888; and (3) a country branch at Drumchapel, Dumbartonshire, containing 80 cots, opened in 1903. Children treated must not be over 13 years of age, nor suffer from infectious diseases. In 1928 there were 6402 patients treated in the wards, and the number of attendances of out-patients was 90,585. There are one professorship and four lectureships in the University of Glasgow in connexion with the hospital, one professorship and one lectureship on the Medical Diseases of Infancy and Childhood, one lectureship on Surgery and Orthopædics in Relation to Infancy and Childhood, one lectureship on Biochemistry in Relation to Infancy and Childhood, and one research lectureship on the Pathology of the Diseases of Infancy and Childhood. The lectures are both systematic and clinical, but particularly and chiefly the latter. In addition, special facilities are given for post-graduate study.

Full information may be obtained from the Medical Superintendent.

The Glasgow Royal Maternity and Women's Hospital, Rottenrow.—The average daily number of patients in the hospital is 140, and of the 4000 cases admitted to the wards per annum, over 60 per cent. are classified as abnormal. There are also about 3500 mothers attended per annum in their own homes. The work of the antenatal wards with their 40 beds is supplemented by large antenatal clinics where over 4000 new patients are seen in the course of the year. Splendidly equipped Research Laboratories were opened in 1926. The Visiting Staff of the hospital includes a Pædiatrician, who gives daily attendance. The practice of the hospital affords a wonderful field for post-graduate study and experience. In addition to the joint courses for post-graduates as organised by the Glasgow Post-Graduate Association, the resources of the hospital are always available for those who wish to make a special study of obstetrics. Inquiries should be addressed to the House Superintendent.

Royal Samaritan Hospital for Women, Glasgow. Increased to 160 beds by building extensions completed in 1927. It offers excellent facilities for clinical instruction in the diseases peculiar to women. Lectures and clinical demonstrations are given by members of the surgical staff to students and to post-graduates; and the hospital is represented on the Board of the Glasgow Post-Graduate Medical Association formed for coördinating post-graduate medical teaching in all the hospitals. The Royal Samaritan Lectureship in Gynæcology is a University Lectureship associated with the hospital.

For further information, application may be made at the hospital, or to the Secretary, 200, St. Vincent-street, Glasgow.

Glasgow Lock Hospital, 41, Rottenrow, Glasgow. Contains 80 beds for the treatment of females suffering from Venereal Diseases. There is also a Labour Ward, and a well-equipped Dispensary for out-patient attendances. There is a Lecture Room and a Laboratory, equipped with modern appliances, where University classes on the subject are dealt with. Post-graduate classes are also held. Recently the hospital has been completely renovated and modernised. Full information from the Secretary and Treasurer, Mr. J. Neilson Gray, LL.B., 65, Bath-street, Glasgow.

Glasgow Ophthalmic Institution, 126, West Regent-street, and 131, Wellington-street (30 beds and six cots).—This institution is administered by the Royal Infirmary. Clinical and systematic courses of lectures for students during the winter and summer sessions. Operations on Wednesdays, Thursdays, and Fridays. Post-graduate classes and demonstrations are arranged during the summer. For information regarding fees and other particulars, application should be made to the Superintendent, Royal Infirmary.

Glasgow Eye Infirmary, Berkeley-street and Charlotte-street.—The wards and dispensary are recognised by the University of Glasgow for the purpose of instruction in ophthalmology for graduation in medicine, and by the Royal Colleges of Physicians and Surgeons of England for the Diploma in Ophthalmic Medicine and Surgery. A Venereal Centre has been established, and a Branch Dispensary has been opened in Clydebank. Post-graduate Classes are held. Secretary and Acting Treasurer, Mr. William M. Moore, 171, West Regent-street, Glasgow.

GLASGOW EAR, NOSE, AND THROAT HOSPITAL, 306, St. Vincent-street (52 beds).—At out-patient and indoor departments clinical instruction is given. A Research Department has now been installed. Post-graduate Courses are held during the year. Secretary: D. N. Mackay, 144, St. Vincent-street, Glasgow.

UNIVERSITY OF ST. ANDREWS (UNITED COLLEGE ST. ANDREWS AND UNIVERSITY COLLEGE, DUNDEE).

Four Degrees in Medicine and Surgery are conferred by the University of St. Andrews—viz., *M.B.*, *Ch.B.*, *M.D.*, *Ch.M.*, a Diploma in Public Health, and Diploma in Dental Surgery (*L.D.S.*).

The extent and standard of the Preliminary Examination is determined by the Scottish Universities Entrance Board constituted under Ordinance No. 70 of the Scottish University Courts (General No. 3—Regulations as to Admission to the Scottish Universities for purposes of graduation), in accordance with the terms of that Ordinance. A degree in Arts or in Science in any of the Universities of the United Kingdom and in some colonial and foreign universities exempts. The Preliminary Examination for graduation in Medicine and Surgery, Arts or Science, of the University of St. Andrews is accepted as equivalent to the Registration Examination required by the General Medical Council (the certificate to include the required subjects). Also the Final Examination for a degree in Arts or Science.

Degrees of Bachelor of Medicine and Bachelor of Surgery.—A pre-registration examination is held in Physics and Chemistry. Candidates must have been engaged in medical study for at least five years. In each of the first four years the candidate must have attended at least two courses of instruction in one or more of the subjects of study specified below, each course extending over a session of not less than five months, either continuous or divided into two terms, or, alternatively, one such course along with two courses, each extending over a session of not less than two and a half months. During the fifth or final year the candidate shall be engaged in clinical study for at least nine months at the Infirmary of Dundee or at one or more of such public hospitals or dispensaries, British or foreign, as may be recognised for the purpose by the University Court. The candidate must have received instruction in each of the following subjects of study, including such examinations as may be prescribed in the various classes—viz., Anatomy, Practical Anatomy, Chemistry, Materia Medica, Physiology, Practice of Medicine, Surgery, Midwifery and the Diseases peculiar to Women and Infants, Pathology, Bacteriology, Practical Chemistry, Physics, Elementary Botany, Elementary Zoology, Practical Physiology, Practical Pathology, Forensic Medicine, and Public Health. The candidate must have attended for at least three years the Medical and Surgical Practice either of the Infirmary of Dundee or of a General Hospital elsewhere with not fewer than 80 patients, with a distinct staff of physicians and surgeons, and recognised for the purpose by the University Court. Additional subjects of study are Practical Pharmacy, Mental Diseases, Practical Midwifery, Operative Surgery, Vaccination, Children's Diseases, Fevers, Ophthalmology, Diseases of the Ear, Throat, and Nose, Anæsthetics, Dermatology, Venereal Diseases, Tuberculosis, and Post-mortem Examinations.

With respect to the places and institutions at which the studies of the candidate may be prosecuted the following regulations shall have effect:—1. Two of the five years of medical study must be spent in the University of St. Andrews. 2. The remaining three years may be spent in any University of the United Kingdom or in any Indian, Colonial, or Foreign University recognised for the purpose by the University Court, or in such medical schools or under such teachers as may be recognised for the purpose by the University Court. Women are admitted to graduation in Medicine.

Professional Examinations for the Degrees of Bachelor of Medicine and Bachelor of Surgery.—Each candidate will be examined both in writing and orally, and also clinically where the nature of the subject admits, in the following divisions—viz., first, in Botany, Zoology, Physics, and Chemistry; second, in Anatomy and Physiology; third, in Materia Medica, Pathology and Bacteriology, Forensic Medicine and Public Health; and fourth, in Surgery, Clinical and Operative Surgery, Practice of Medicine and Clinical Medicine, and Midwifery and Gynæcology (Systematic and Clinical).

UNIVERSITY COLLEGE, DUNDEE.—The Medical School in St. Andrews University is carried on as follows. Part or whole of the medical curriculum of St. Andrews University must be taken here. Provision is made by St. Andrews University for instruction in the work of the first two years, including Anatomy and Physiology, in both St. Andrews and Dundee. The last three years of the curriculum must be taken in Dundee in University College, which is a constituent part of St. Andrews University.

ROYAL INFIRMARY, *Dundee (461 beds).—In addition* to the ordinary Medical and Surgical Wards, there are special departments for Midwifery (In- and Out-door), for Diseases of Women, of Children, of the Eye, of the Ear, Nose, and Throat, and of the Skin; and for Clinical Pathology, Radiology, Electrotherapeusis, and Electrocardiography. An extension providing for a new X Ray Department and Massage Department and for additional Operation Theatre accommodation has been opened recently, a new Maternity Department is being built at a cost of £32,000, and a new Dispensary at a cost of £25,000. Clinical teaching is given to male and female students by the Honorary Staff; post-mortem examinations are conducted by the pathologists. All courses of instruction are recognised by the University of St. Andrews and the other Universities and Boards of the United Kingdom. Ten Resident Medical Officers are appointed every six months. Clinical clerks and dressers are attached to the Physicians and Surgeons; and Students are appointed as assistants in the pathological department. Further information may be obtained from the Medical Superintendent.

UNIVERSITY OF ABERDEEN.

The University of Aberdeen grants four degrees in Medicine and Surgery—viz., *M.D.*, *Ch.M.*, *M.B.*, and *Ch.B.* The Degree of Doctor of Philosophy (*Ph.D.*) is also granted in the Faculty of Medicine.

Degrees of M.B. and Ch.B.—Candidates, before entering on the curriculum, must have passed the Preliminary Examination or hold a qualification recognised as exempting from such examination, have attained the age of 17, and have passed the Pre-registration Examination in Physics and Chemistry.

The curriculum for the degrees extends over a period of five years, during which attendance is required in the following subjects: Botany, Zoology, Physics, Chemistry (Systematic and Practical), Anatomy (Systematic and Practical), Physiology (Systematic and Practical), Materia Medica and Therapeutics, Practical Pharmacy, Pathology (Systematic and Practical), Medical Jurisprudence, Public Health, Surgery, Medicine, and Midwifery.

Candidates must attend for at least three years the medical and surgical practice of a recognised hospital, they must have attended courses of at least nine months in clinical medicine and clinical surgery, and have acted as clerk in the medical and dresser in the surgical wards of a hospital. Attendance is required on the practice of a dispensary or the out-practice of a hospital and also on courses in Mental Diseases, Fevers, Ophthalmology, Post-mortem Examinations, Venereal Diseases, Tuberculosis, Radiology, X Ray, Therapeutics and Electrical Treatment, and Clinical Chemistry, and other special subjects. The candidate is also required to have been properly instructed in Vaccination and to have attended at least 20 Midwifery cases.

Degrees of M.D. and Ch.M.—Candidates for either of these degrees must already hold the degrees of M.B. and Ch.B. of Aberdeen. A thesis (in duplicate) has to be presented and an examination has to be passed in Clinical Medicine (or in some special Department of Medical Science) or Clinical Surgery, as the case may be.

Degree of Ph.D.—For this degree candidates must pursue a course of special study or research during a period of nine academical terms as Research Students in the University of Aberdeen or in any College or Institution that may be affiliated thereto. A Thesis (in duplicate) must be presented for approval.

A diploma in Public Health is granted by the University to graduates in Medicine of a University in the United Kingdom, after a special examination.

Scholarships and Prizes.—In the Faculty of Medicine of the University of Aberdeen there are the following Bursaries, Scholarships, and Prizes:—Bursaries: about 15 Bursaries (competition and presentation) are open each year, of £15 to £45 per annum in value, most of them being tenable for three years. Scholarships: five Post-graduate Scholarships, value £36 to £100 per annum. Prizes and Medals: 15 Gold Medals and Prizes for proficiency in special departments.

ABERDEEN ROYAL INFIRMARY (800 beds).—The main clinical work of the students is done in the infirmary with its general and special facilities, including a Department of Clinical Chemistry.

ABERDEEN ROYAL MENTAL HOSPITAL.—This hospital contains about 900 beds. The class of Mental Diseases meets at the University of Aberdeen, and clinical instruction is given at the hospital during three months in summer. Physician-Superintendent, Dr. R. Dods Brown.

OTHER HOSPITALS.—Students have the opportunity of attending the following institutions: City Fever Hospital, Sick Children's Hospital, General Dispensary, Lying-in and Vaccine Institutions, and Ophthalmic Institution.

SCOTTISH MEDICAL CORPORATIONS GRANTING DIPLOMAS.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH, ROYAL COLLEGE OF SURGEONS OF EDINBURGH, ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.

These Colleges have made arrangements by which, after one series of examinations, held in Edinburgh or Glasgow, or both, the student may obtain the diplomas of the three bodies. This is the Scottish Conjoint Board.

The three bodies grant their Single Licences only to candidates who already possess legal qualifications in Medicine or Surgery.

The hospitals which are recognised by the Scottish Conjoint Board as places where professional study for their diplomas can be pursued are all those institutions which feed the medical faculties of the universities, as well as all the places which are recognised by the English and Irish Conjoint Boards.

Professional Education.—The candidate must produce certificates or other satisfactory evidence of having attended the following separate and distinct courses of instruction: Physics, three months; Elementary Biology, 2 terms; Elementary Organic Chemistry, one term; Anatomy, Practical Anatomy, 5 terms; Theoretical, including Biochemistry and Biophysics, 5 terms; Physiology, Materia Medica, 2 terms; Pathology (including Practical Pathology), 3 terms; Practice of Medicine, 2 terms; Clinical Medicine, 3 terms; Principles and Practice of Surgery, 2 terms; Clinical Surgery, 3 terms; Midwifery and Gynæcology, 2 terms; Diseases of Children one term; Medical Jurisprudence, one term; and Public Health, one term. The certified attendance on lectures, demonstrations, and practical work must not be less than three-fourths of the total number of roll-calls. Every student undergoes a course of Practical Midwifery, but before attending at labours he is required to attend a course of lectures on Surgery and Midwifery and to hold the offices of Clinical Medical Clerk and Surgical Dresser. He must also attend for two and a half months' instruction in Practical Pharmacy; the certificate to be signed by the teacher, who must be a member of the Pharmaceutical Society of Great Britain, or the superintendent of the laboratory of a public hospital or dispensary, or a registered practitioner who dispenses medicines to his patients, or a teacher of Practical Pharmacy.

The student must attend for 27 months the Medical and Surgical practice of a public general hospital containing on an average at least 80 patients available for clinical instruction, and possessing distinct staffs of physicians and of surgeons. He must act as Surgical Dresser and Medical Clinical Clerk for not less than nine months in the wards in each case, and receive practical instruction in administration of anæsthetics. He must attend for three months the practice of a public dispensary especially recognised by any of the above authorities, and three months' attendance at the out-patient department of a recognised general hospital. This attendance should be made after the student has passed the First and Second examinations.

Candidates are also required to attend the following courses: *Diseases and Injuries of the Eye*, three months; Insanity, three months; Infectious Diseases, three months; Gynæcology, three months; Diseases of Children, three months.

The curriculum lasts for five years, the fifth year being devoted to clinical work.

There are four professional examinations:—

First Examination includes Systematic and Practical Biology.

The *Second Examination* must be Written, Practical, and Oral, and consist of the following subjects:—(1) Anatomy and Embryology, and (2) Physiology, including Histology (if not included in Anatomy), Biochemistry, and Biophysics. Candidates may be admitted to this Examination on production of the necessary certificates of curriculum.

The *Third Examination* must be Written, Practical and Oral, and consist of the following subjects:—(1) Pathology, including Bacteriology and Morbid Anatomy, and (2) Pharmacology (Theoretical and Practical), including Pharmacological Chemistry, the Principles of Therapeutics, the methods of Treatment by Vaccines and Sera, and Prescription Writing. Candidates may be admitted to this Examination on production of the necessary certificates of curriculum.

The *Final Examination* must consist of the following subjects[1]:—(1) Medicine, including Therapeutics, Applied Anatomy and Physiology, and Clinical Pathology with Practical Medicine; (2) Surgery, including Applied Anatomy and Physiology, Clinical Pathology, with Practical Surgery; (3) Midwifery and Diseases of Women, Clinical Obstetrics and Gynæcology, with Practical Midwifery; and (4) Medical Jurisprudence and Public Health. Medicine, Surgery, and Midwifery must be taken together, and Medical Jurisprudence and Public Health, and not earlier than on the conclusion of five Winters and five Summers of Medical Study, provided that a period of 30 months has elapsed since passing the Second Professional Examination. The Schedule for the

---

[1] Candidates at the Final Examination may be examined on Diseases of Children, Fevers, Tuberculosis, Insanity, Skin Diseases, *Diseases and Injuries of the Eye, Diseases of the Ear, Throat, and Nose*, Radiology, Venereal Diseases, Orthopædics, Vaccination, and Anæsthetics.

Final Examination must contain a summary of the entire Course of Study, and, properly attested or proved by Certificates, must be lodged with the Inspector, and the fee paid, *not later than one week before the examination.* At the same time there must be produced a Certificate to show that the Candidate is not less than 21 years of age. No Candidate can be exempted from examination on any subject of the *Final Examination* (with the exception of Medical Jurisprudence and Public Health) unless he has already passed in the subject at this Board.

In addition to the Written and Oral Examinations, all Candidates must be subjected to Clinical Examinations in Medicine, Surgery, and Midwifery and Gynæcology, which shall include the Examination of Patients, Physical Diagnosis, the Clinical use of the Microscope and of other instruments, Clinical Chemistry, Surgical Appliances, Bandaging, Surface markings, Skiagrams, &c. The Oral Examination include the recognition of specimens. All Candidates for the Final Examination must complete the three portions (Medicine, Surgery, and Midwifery) within a period of 19 months.

There are four periods of examination annually.

The Registrar in Edinburgh is Dr. David Thomson, 49, George-square; and the Registrar in Glasgow, Mr. Walter Hurst, 242, St. Vincent-street, to whom fees and certificates must be sent for the respective examinations, and from whom particulars of fees can be obtained.

SCHOOL OF MEDICINE OF THE ROYAL COLLEGES, Edinburgh.—The number of students varies much in the classes and subjects. It is within the limit to say that about 1000 students avail themselves each session of the opportunity of attending the school. The lectures qualify for the University of Edinburgh and other Universities, the Royal Colleges of Physicians and Surgeons of London, Edinburgh, and Dublin, the Faculty of Physicians and Surgeons of Glasgow, and other Medical and Surgical and Public Boards. Special courses of instruction for dental students are also included in the curriculum of this school. The practical classes and laboratories will open and the lectures commence on Oct. 1st. In accordance with the statutes of the University of Edinburgh one-half of the qualifying classes required for graduation may be attended in this school. The regulations require that the fee for any class taken for graduation in Edinburgh shall be the same as that for the corresponding class in the University. The whole education required for graduation at the University of London may be taken in this school. Post-graduate Courses are conducted in conjunction with the University. Further particulars regarding the school, also its calendar (price 6*d.*) may be had on application to the Dean of the School, Surgeons Hall, Edinburgh.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH.

In addition to the diplomas granted by the Scottish Conjoint Board the Royal College of Physicians grants its Single Licence to candidates already possessing legal qualifications for professional practice.

The Royal College of Physicians of Edinburgh grants a *Membership* and a *Fellowship.*

Membership.—A candidate, who must be a Licentiate of a British or Irish College of Physicians, or a graduate in medicine of a University, approved by the Council, and 24 years of age, is examined in medicine, therapeutics, and in any branch of the departments of medicine specially professed, such as general pathology, psychology, public health, obstetrics, gynæcology, diseases of children, tropical medicine, or [illegible]ical jurisprudence.

F[illegible] the Fellows are elected from the

ROYAL COLLEGE OF SURGEONS OF EDINBURGH.

The Royal College of Surgeons of Edinburgh admits to the examination for its Single Licence any candidates who hold a Diploma in Medicine of any British, Indian, or Foreign university or of any British College of Physicians, or of the Society of Apothecaries of London or Apothecaries' Hall, Dublin, granted under the provisions of the Medical Act, 1886, whose preliminary examination and course of professional study is proved to be sufficient to fulfil the requirements of the College, or to those who have passed a full examination for any of the above. Female practitioners are admitted to the Licence of the College and also to the Fellowship, and the regulations apply to practitioners of either sex.

The College grants a diploma of Fellowship after examination to the holders of British surgical degrees or diplomas and the holders of recognised degrees of the Universities of Canada, Australia, New Zealand, and the Indian Empire.

The Fellowship.—Candidates must be 25 years of age and in practice for at least two years. The examination is written and viva voce, and includes surgery and surgical anatomy, operative surgery, and clinical practice. One optional subject must also be taken, the range of these specialisms covering nearly every branch of medicine. Candidates are not allowed to appear for more than three times at the examinations. One month's notice of intention to appear for examination must be given by the candidate to the College.

THE ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.

The Royal Faculty of Physicians and Surgeons of Glasgow grants a Fellowship and a Licence to be held separately. The Licence is granted as a separate qualification to qualified practitioners in Medicine after examination in surgery, including surgical anatomy and clinical surgery.

Fellowship.—The Fellowship of the Faculty is granted after examination in medicine or surgery, together with an optional subject, which may be anatomy or physiology or be selected from any special branch of medicine or surgery. Fourteen days' notice must be given by the candidate to the Faculty. In certain circumstances Fellows may be elected as a mark of distinction.

III.—IRELAND.

THE UNIVERSITIES.

UNIVERSITY OF DUBLIN, TRINITY COLLEGE (SCHOOL OF PHYSIC).

Matriculation.—University students take the Entrance of Trinity College and a Junior Freshman Term or a special Medical Preliminary; Extern Students, any examination recognised by the General Medical Council.

Pre-registration Examination in Elementary Physics and Chemistry.—Before beginning the five years' Medical curriculum students must pass an examination in elementary Physics and Chemistry. This examination is held at the end of September, in January, in March, and in July. Courses in preparation for it may be taken in the School of Physic.

Degrees in Medicine (M.B.), Surgery (B.Ch.), and Midwifery (B.A.O.).—Candidates for these degrees must be of B.A. standing and must be for at least five academic years on the books of the Medical School, reckoned from the date of registration. The Arts course may be taken concurrently with the Medical course, and the B.A. degree need not be taken before the final medical examinations, but the Medical degrees are not conferred without the Arts degree. The following courses must be attended:—(1) Botany, Zoology, Physics and Chemistry; Descriptive and Applied Anatomy; Histology, Physiology and Applied Physiology; Pathology and Bacteriology; Materia Medica and Therapeutics; Medical Jurisprudence and Hygiene; Practice of Medicine; Surgery; Midwifery and Gynæcology. (2) Three courses of nine months' attendance on the Clinical Lectures of Sir Patrick Dun's or other recognised Hospital; (3) Practical Vaccination, one month's instruction; (4) Mental Disease, three months; (5) Practical Midwifery with Clinical Lectures, including not less than 20 personally conducted cases, six months; (6) Ophthalmic Surgery, three months. Three groups of examinations have to be passed. Preliminary Scientific Examination, including Physics and Chemistry, Botany, and Zoology. The Intermediate Medical, Part I., including Anatomy, Physiology, and Organic Chemistry; and Part II., including Applied Anatomy and Applied Physiology; and the Final Examination, which is divided into Part I., Materia Medica and Therapeutics, Hygiene and Jurisprudence, Pathology and Bacteriology; and Part II., Medicine, including Clinical Medicine and Mental Diseases; Surgery, including Operative and Ophthalmic Surgery; Midwifery and Gynæcology. Part I. may be passed in the fourth year, and Part II. completed at the end of the fifth.

Doctor in Medicine.—A Doctor in Medicine must have passed all the qualifying examinations and must be a B.A. of three years' standing. He must also submit a thesis and pass an Examination before the Regius Professor of Physic.

Master in Surgery.—A Master in Surgery must be a Bachelor in Surgery of the University of Dublin of not less than three years' standing, and must produce satisfactory evidence of having been engaged for not less than two years from the date of his registration in the study, or study and practice, of his profession. He must then pass a special examination.

Master in Obstetric Science.—A Master in Obstetric Science must be a Bachelor in Obstetric Science of two years' standing, and must produce evidence of having been engaged in the study of Obstetric Medicine and Surgery during two years. He is then required to pass a special examination.

Diploma in Gynæcology and Obstetrics.—A post-graduate diploma is conferred upon registered medical practitioners who take a six months' course at the Rotunda Hospital or other recognised institution, a six months' course in Trinity College, and then pass a special examination. The minimum time required for the complete course is nine months.

Bachelor in Dental Science and Master in Dental Science.—The regulations under which these degrees are awarded can be obtained by application to the Registrar of the School of Physic.

All Degrees and Courses of Instruction are open to women students.

Scholarships and Prizes.—1. Medical and Surgical Travelling Prizes, £100, awarded in alternate years. 2. Bicentenary Memorial Prize, £30, awarded yearly, and given to the Travelling Prizeman. 3. Sir John Banks Prize and Medal. 4. Edward Hallaran Bennett Prize and Medal. 5. FitzPatrick Scholarship, awarded on results of Final Examination (interest on £1000). 6. Medical Scholarship, £20 per annum for two years, awarded in Chemistry, Physics, Botany, and Zoology. 7. Medical Scholarship in Anatomy and Physiology, £20 per annum for two years. 8. Henry Hutchinson Stewart Scholarships, one in Botany, Zoology, Chemistry and Physics, and another in Anatomy and Physiology, awarded annually and valued at £10 per annum for three years. 9. Henry Hutchinson Stewart Scholarship in Mental Diseases, awarded from time to time, £50 per annum for three years. 10. John Mallet Purser Medal, awarded annually in Physiology. 11. Daniel John Cunningham Medal and Prize, awarded annually in Anatomy. 12. Begley Studentship, £40 per annum for four years, awarded annually. 13. Kingsmill Jones Memorial Prize, awarded annually in Natural and Experimental Science, £15. 14. O'Sullivan Memorial Scholarship, £48 awarded annually for excellency of record in school.

Post-graduate Instruction.—Arrangements have been made, with the approval of the Board of Trinity College, for a post-graduate course of instruction at the School of Physic during the autumn from Monday, Sept. 16th, to Saturday, Oct. 5th. A limited number of members of the class can reside in college rooms and dine on commons. Women graduates can be accommodated at Trinity Hall.

HOSPITALS AFFORDING PRACTICE RECOGNISED BY THE IRISH UNIVERSITIES AND CORPORATIONS.[1]

SIR PATRICK DUN'S HOSPITAL, Grand Canal-street, Dublin.—Classes both in Medicine and Surgery are held each morning from 9 o'clock from Oct. 1st till the end of June. Special classes for junior students will be held in the wards during the months of October, November, and December. A Resident Surgeon, with salary, is appointed annually. Six Resident Pupils are appointed every six months. Twelve surgical Dressers and twelve Clinical Clerks are appointed each month. There are facilities for women students.

The practice of the hospital is open to all students, and the certificates are recognised by Dublin University, the National University and Royal Colleges of Surgeons of England, Ireland, and Scotland. It is an official "Treatment Centre" for venereal diseases.

Prizes and Medals.—Clinical medals and prizes amounting to about £21 each will be awarded in Medicine and in Surgery respectively in accordance with the will of the late Rev. Samuel Haughton, M.D., S.F.T.C.D. Candidates who fail to obtain these medals and prizes will be awarded special certificates in Medicine and in Surgery provided they show sufficient merit.

Further information will be supplied by the Hon. Secretary to the Medical Board.

ADELAIDE HOSPITAL, Peter-street, Dublin.—Two resident surgeons are elected half-yearly and four or more resident pupils every six months. At the termination of the session prizes in Clinical Medicine, in Surgery, in Gynæcology, and in Dermatology will be awarded.

Prizes.—Wallace Beatty Memorial bursaries are awarded at the commencement of the winter session. In addition to the junior prizes the Hudson Scholarship, £30 and a gold medal, as well as a prize of £10 together with a silver medal, are awarded at the end of the session for proficiency in medicine, surgery, gynæcology, and pathology.

The certificates of attendance are recognised by all the Universities and licensing bodies in the United Kingdom. Further particulars may be obtained from the Secretary of the Hospital.

MATER MISERICORDIÆ HOSPITAL, Dublin. (Under the care of the Sisters of Mercy.)—This Hospital, containing 410 beds, is open at all hours for the reception of accidents and urgent cases. Clinical instruction is given by the Physicians and Surgeons at 9 A.M. daily. Ophthalmic Surgery is taught in the Special Wards and in the Dispensary. Surgical operations are performed daily. Connected with the hospital are extensive Dispensaries, which afford valuable opportunities for the study of general Medical and Surgical Diseases, and Accidents; a fully-equipped Biochemical Laboratory, a modern Electro-Massage Department, and Electrocardiograph room. Instruction is given on Pathology and Bacteriology. Three House Physicians, eight House Surgeons, and 18 resident pupils are elected annually. Dressers and Clinical Clerks are appointed regularly and certificates given for merit. Leonard Prizes will be offered for competition annually. Certificates of attendance are recognised by all the Universities and licensing bodies in the United Kingdom. There is a Private Hospital for the reception of Medical and Surgical cases. A Training School and a Home for Trained Nurses are connected with the Hospital, and Nurses who have passed a qualifying examination can be obtained on application to the Lady Superior.

---

[1] This list of the institutions recognised by the Conjoint Board of Ireland is supplemented in the regulations of the Colleges by those hospitals mentioned as recognised institutions in Scotland and England. The recognised facilities for clinical instruction in some of the Irish centres have been described.

Entries can be made with any of the physicians or surgeons, or with the Registrar, 31, Fitzwilliam-square. Detailed information may be obtained from the Secretary, Medical Board.

MERCER'S HOSPITAL.—This hospital contains 120 beds for medical and surgical cases, and arrangements have been made with the medical officers of Cork-street Fever Hospital whereby all students of this hospital are entitled to attend the clinical instruction of that institution and become eligible for the resident posts. There is a large dispensary for out-patients and a modern X ray department. An electrocardiograph has been installed. Students of the hospital are permitted to attend the gynæcological department, where they receive practical instruction. There are special wards for the treatment and study of children's diseases. A gold medal is awarded annually to the best student. During the past few years the hospital has undergone extensive alterations in order to bring it up to modern requirements. A House Surgeon is appointed annually. There are six men and two women Resident Pupils, and Clinical Clerks and Dressers are appointed from members of the classes.

For further particulars apply to Dr. Leonard Abrahamson, Hon. Sec., Medical Board, 40, Fitzwilliam-place.

RICHMOND, WHITWORTH, AND HARDWICKE HOSPITALS (HOUSE OF INDUSTRY HOSPITALS), DUBLIN.—These hospitals contain 330 beds—130 for Surgical Cases, 80 for Medical Cases, 78 for Fever and other Epidemic Diseases, and an Auxiliary Wing with 42 beds, devoted mainly to throat, nose and ear and skin diseases. Two Resident Physicians and two Resident Surgeons are appointed each half year, in addition to a Resident Pathologist and a Resident Anæsthetist. Resident Clinical Clerks are appointed each quarter, and it has always been the aim of the Medical Board to ensure that each student spends at least six months in residence. Women students are eligible on the same terms as men. Ample facilities exist for post-graduate work in the various special departments, as well as in general medicine and surgery. Extensive alterations and improvements have recently been made in the X ray, Electrotherapeutic, and Electrocardiographic departments. For further information apply to Hon. Sec., Medical Board.

ROYAL CITY OF DUBLIN HOSPITAL.—158 beds and a special wing for the treatment of fevers and contagious diseases founded by the late Mr. Drummond. There is a large nursery where special opportunities are afforded for the study of diseases of children, both medical and surgical. There are also special wards for ophthalmic, aural, and gynæcological cases; also a department for the Erlangen Treatment by Deep Therapy. There is a largely attended out-patient department, where students are allowed to attend accidents and dress cases under supervision. Six resident pupils are appointed every three months. A House Surgeon and a House Physician are appointed annually. For information apply to the Secretary.

DR. STEEVENS' HOSPITAL, Dublin (Kingsbridge).—250 beds, only 150 now in use. There is accommodation for 10 resident pupils, each of whom is provided with a separate bedroom, and board is supplied by the hospital at a reasonable rate. There is an Electric Massage Department, a "Sun-Ray" and Diathermy Department, and an X Ray Department. There are also two V.D. wards and a largely attended V.D. Treatment Centre. All information with regard to the terms for such residency can be had from the Resident Surgeon at the Hospital. Secretary: E. D. F. Banks.

MEATH HOSPITAL AND COUNTY DUBLIN INFIRMARY.*

JERVIS-STREET HOSPITAL, Dublin.*

ROTUNDA HOSPITAL, Dublin.—This institution is the largest combined gynæcological and maternity hospital in the British Empire. Over 4000 confinements are attended annually and upwards of 1000 gynæcological patients admitted. Students can take out their necessary gynæcological and midwifery practical courses. The work of the hospital is carried on continuously through the year, and consists of daily clinical instruction in the maternity department and examination and operations in the gynæcological department. Qualified students are given facilities for studying and assisting in the management of all abnormal cases so far as is practical. An antenatal dispensary is held three times weekly and all students are encouraged to attend. A special class in gynæcological examination and diagnosis is conducted by the Assistants to the Master. In addition there is a special class in operative obstetrics, limited in number. The pathological laboratory is under the supervision of a skilled pathologist, who gives special classes at intervals. There is a fully equipped X ray installation under the care of a competent radiologist. A ward has been opened for the treatment of infantile conditions, and is under the care of a pædiatrician, who gives instruction in the out-patient department, which is held daily. The appointments on the staff of the hospital are given to qualified past students of the hospital who have taken the L.M. and consist of Extern Assistants for six months, one being appointed every three months. From these the Assistants to the Master are appointed. Women students can reside in the hospital on the same terms as men. The mess room and sleeping quarters have been decorated recently and reading rooms are provided. The L.M. is granted by examination after a six months' course. Fees for Intern students: one month £6 6*s.*, months other than the first £4 4*s.*, three months £12 12*s.*, six months £21. Special gynæcological class £2 2*s.* per month. For further particulars apply to the Master, Dr. Bethel Solomons, F.R.C.P.I.

COOMBE LYING-IN HOSPITAL AND GUINNESS DISPENSARY FOR THE TREATMENT OF DISEASES PECULIAR TO WOMEN, Dublin.—This hospital contains 70 beds and consists of two divisions, one of which is devoted to lying-in cases and the other to the treatment of diseases peculiar to women. Lectures are delivered, practical instruction given, and gynæcological operations are performed in the theatres daily. There is a general dispensary held daily, at which instruction is given on the Diseases of Women and Children. There is a special afternoon dispensary held by the Master and his assistants, at which practical instruction in gynæcology is given. There is no extra charge for attendance at this Dispensary. There is accommodation for intern pupils, who enjoy exceptional advantages of acquiring a thorough knowledge of this branch of their profession. Women students can reside in the hospital. Clinical assistants are appointed from amongst the pupils as vacancies occur. Certificates of attendance at this hospital are accepted by all licensing bodies. Students can enter for attendance at any time, but preference is given to those entering from the first day of the month. Further particulars may be had on application to the Master or the Registrar at the Hospital.

---

* No returns.

NATIONAL MATERNITY HOSPITAL, Holles-street, Dublin.—Established 1894. The hospital consists of Intern and Extern Maternity, Gynæcological Wards, and a Dispensary for the treatment of Diseases of Women and Children and an antenatal and postnatal branch. Every facility is given for the carrying out of practical work. Undergraduate and post-graduate courses are arranged at any time. Certificates of attendance at this hospital are recognised by all the licensing bodies. Clinical lectures are given daily and Oral lectures four times per week. The L.M. Diploma is given by special examination, which is held three times a year. Further particulars can be obtained from P. T. McArdle, Esq., M.B., the Master, or from the Secretary, Holles-street, Dublin.

ST. VINCENT'S HOSPITAL AND DISPENSARY, Dublin. —Established 1834. 200 beds. Clinical Lectures in Medicine and Surgery are held from October to June. Special classes for Juniors from October to December. Pathological and Bacteriological Demonstrations are given every Thursday, and instructions in the use of Laryngoscope and Otoscope for senior students every Saturday. Medals and Prizes: the Bellingham gold medal in Medicine and the O'Ferrall gold medal in Surgery are offered for competition at the end of the summer session, as well as junior prizes, also the McArdle Memorial Prize, value £20. There are a large Extern Department and a new Pathological Laboratory. Hon. Secretary Medical Board, Wm. Doolin, M.B., F.R.C.S., 2, Fitzwilliam-square, Dublin.

NATIONAL UNIVERSITY OF IRELAND.

Matriculation.—All students must pass a matriculation examination; the examination taking place in June and September in Dublin, and at certain local centres, includes five subjects, three of which must be Irish, English, and mathematics. All students must pass in Irish except students not born in Ireland, and other students whose home residence shall have been outside Ireland during the three years immediately preceding their matriculation; but all such students will be expected to attend a course of instruction in Irish Literature and History prior to obtaining any degree in the University. The following are the subjects for examination:—(1) Irish. (2) Latin. (3) Greek. (4) French. (5) German. (6) Italian. (7) Spanish. (8) Portuguese. (9) Welsh, *or any other modern language approved by* the Senate. (10) English. (11) Mathematics. (12) History. (13) Geography. (14) Applied Mathematics, or (15) Physics as an alternative. (16) Chemistry. (17) Botany. (18) Agricultural Science. (19) Commerce. (20) Music, and for women candidates only (21) Physiology and Hygiene. Students entering for degrees in Medicine or Dentistry, if not already registered by the General Medical Council, must take Irish, Latin, English, Mathematics, and a fifth subject.

The medical degrees granted are:—

M.B., B.Ch., B.A.O.; M.D., M.Ch., M.A.O., Ph.D.—Printed forms of application for admission to any medical examination may be had from "The Registrar, The National University of Ireland, Dublin."

The Constituent Colleges of the National University of Ireland at which the full curriculum for medical degrees can be obtained are University College, Dublin; University College, Cork; and University College, Galway.

UNIVERSITY COLLEGE, DUBLIN.—*Matriculation.*—Almost all the students of the College are matriculated students of the National University of Ireland. The pre-registration examination in physics and chemistry is taken after matriculation either at the beginning of or during the winter session. The course is of five years' duration and dates from the passing of the pre-registration examination.

Degrees of M.B., B.Ch., and B.A.O.—The First Examination includes Applied Physics, Applied Chemistry, Botany, Zoology, and Applied Biology. The examination may be taken in two parts: Part I., Physics and Chemistry; Part II., Botany and Zoology. Honours may be obtained only when both parts are taken as one examination. The Second Examination includes Anatomy and Physiology. Both must be passed at the same time. The Third Examination (Part I.) includes Pathology, Materia Medica, Pharmacology, and Therapeutics. Part II. (Third Examination), taken at the end of the Fourth Winter Session, includes Hygiene and Medical Jurisprudence.

The Final Examination in Medicine, Midwifery, Surgery, and Ophthalmology includes both the theoretical and the clinical branches. No student can enter for the M.B., B.Ch., or B.A.O. until the end of the fifth year after registration, when the curriculum has been completed. The degree of M.D. may be obtained either by examination or on published work.

A Post-graduate Summer Course is held each year, beginning about the middle of June. The D.P.H. Course extends over the year, beginning at the opening of the session.

UNIVERSITY COLLEGE, CORK: THE SCHOOL OF MEDICINE.—Students must have passed the Matriculation Examination of the University or some other recognised examination, and a preliminary examination recognised by the General Medical Council.

Medical Students who have passed the First Professional Examination of the Conjoint Boards of Ireland, England, or Scotland may be admitted to the rank of second-year students on making application to the Council. Similarly, students who have passed the Second Professional Examination of the same Boards may be admitted to the rank of third-year students; and those who have passed the Third Professional Examination of the Dublin Colleges, or of the Edinburgh Colleges and Glasgow Faculties, may rank as fourth-year.

The school is provided with physiological, toxicological, pathological, and pharmaceutical laboratories, materia medica, anatomical and pathological museums, as well as a collection of surgical and obstetrical instruments and appliances. There are dissecting-rooms, well-appointed physical, chemical, and biological laboratories, a large natural history museum in the adjoining building, and part of the College ground is laid out as a botanical garden. The plant houses are well filled with plants and are open to the students in the class of Botany. The Library contains about 70,000 volumes and is open daily during term time to students. The Medical Museum occupies a large room erected at the northern end of the medical buildings. There are Students' Clubs for men and women students of the College and various athletic clubs.

Residence of Students.—Students not living at home, or with relatives or friends, sanctioned by their parents or guardians, are required to live in a hostel or in recognised lodgings, and register their addresses each session. The Honan Hostel, adjoining the College, is equipped by private endowment. A number of sets of rooms, together with recreation and common rooms, are provided for lay students who may desire to live there. For full particulars apply to the Warden. The Ursuline Convent, Blackrock, has a house of residence, quite separate from their Secondary School, for Catholic women students.

Clinical Instruction.—Students may attend the South Charitable Infirmary and County of Cork General Hospital, Cork North Charitable Infirmary and City of Cork General Hospital, the Mercy Hospital, the Cork District Lunatic Asylum, the Victoria Hospital for Diseases of Women and Children, the County Lying-in Hospital, Bon Secours, Fever, the District, and Ear, Eye, and Throat Hospitals.

Complete information with regard to class fees, scholarships, and prizes can be obtained from the Dean of the Medical Faculty, and in respect of the hospitals from the Secretaries.

UNIVERSITY COLLEGE, GALWAY: SCHOOL OF MEDICINE.—The College contains a well-lighted and ventilated dissecting-room and an anatomical lecture theatre; physiological, pathological, pharmaceutical, chemical, and physical laboratories; anatomical, pathological, gynæcological, and materia medica museums; as well as large natural history and geological museums and an extensive library in which students can read and from which they can borrow books. There are 12 Entrance Scholarships, varying in value from £30 to £60 each, for which Medical Students compete with other students on the Entrance Course. In the Second, Third, and Fourth years three Scholarships in each year, value from £30 to £40 each, are reserved for Medical Students. H. H. Stewart Scholarships (£10 a year for three years) are awarded by the University in Anatomy and Physiology at Second Medical Examination amongst Students of the three constituent Colleges. Travelling Studentships (£200 a year for two years) are offered by the University for competition amongst Medical Graduates of the three Colleges of not more than two years' standing. Women students are eligible for all College and University Degrees, Distinctions, and Prizes. There are extensive grounds, a portion of which is occupied by a Botanic Garden and a portion is at the disposal of the College Athletic Union. There are several student societies in the College, including a Biological Society. There are abundant facilities for research and Post-graduate work in the Chemistry, Physiology, and Pathology departments. There are ample facilities for Women Students. Further information can be obtained from the Registrar of the College.

Clinical Instruction is given in the Galway Tuberculosis Hospital and in the Galway Central and Fever Hospitals, containing on an average 350 patients.

CENTRAL HOSPITAL, GALWAY (300 beds).—In this completely renovated hospital, in addition to the Finer Surgical and Medical Departments, there are now Eye and Ear, Throat and Nose, Gynæcological and Obstetrical, Pathological, X Ray, Ultra-Violet Rays, and Electrical and Massage Departments. Students attend from University College, Galway. Medical and Surgical Clinics are held on alternate days during term. One Resident Physician and one Resident Surgeon are appointed every six months. Resident Students are admitted. The hospital is open to qualified medical men for post-graduate work.

QUEEN'S UNIVERSITY OF BELFAST.

There are six degrees in the Faculty of Medicine of the University—viz., Bachelor of Medicine (M.B.), Bachelor of Surgery (B.Ch.), Bachelor of Obstetrics (B.A.O.), Doctor of Medicine (M.D.), Master of Surgery (M.Ch.), and Master of Obstetrics (M.A.O.). The University also grants a Diploma in Public Health, particulars of which will be found in the University Calendar. The degrees of M.B., B.Ch., and B.A.O. are the primary degrees in the Faculty of Medicine, and are conferred at the same time and after the same course of study. No student is admitted to the final examination for these degrees until he has shown: (1) that he is a matriculated student of the University; (2) that he has completed the prescribed course of study in the Faculty of Medicine extending over a period of not less than five academic years from the date of his registration as a student of Medicine; (3) that he has passed the several examinations prescribed; (4) that he has attended in the University during three academic years at least the courses of study prescribed for such degrees (the Senate may accept, for not more than two academic years of the required five, courses of study pursued in any other University or School of Medicine approved by the Senate); and (5) that he has attained the age of 21 years. Every candidate for admission shall matriculate or fulfil such other test of fitness as may be prescribed by the Senate, or may be exempted from the matriculation examination by having passed similar examinations elsewhere. For information as to Scholarships and Prizes, inquiry should be made of the Secretary of the University.

Primary Degrees of M.B., B.Ch., B.A.O.—All candidates for these degrees must satisfy the examiners in the subjects of four examinations.

The First Medical Examination.—The subjects of this examination are Chemistry (Inorganic and Organic), Experimental Physics, Botany and Zoology. The examination will be divided into two parts which may be taken separately: I., Chemistry and Physics; II., Botany and Zoology.

The Second Medical Examination.—The subjects are Anatomy and Practical Anatomy, Physiology and Practical Physiology. Candidates who have previously passed the First Medical Examination may present themselves for this examination at the close of their second year.

The Third Medical Examination.—The subjects are: (1) Pathology and Practical Pathology; (2) Materia Medica, Pharmacology and Therapeutics; (3) Medical Jurisprudence; (4) Hygiene. Candidates who have previously passed the Second Medical Examination may present themselves for this examination at the close of the third year. Attendance on a course in any subject of the Third Medical Examination shall not entitle a student to a certificate of attendance unless he has previously passed in all the subjects of the Second Medical Examination.

The Fourth Medical Examination.—The subjects are: (1) Medicine; (2) Surgery; (3) Midwifery; (4) Ophthalmology and Otology. This examination may be taken in two parts: I., Systematic; II., Clinical, Practical and Oral. Candidates who have previously passed the Third Examination may present themselves for Part I. of the Fourth Examination at the close of the fourth year, provided that they have fulfilled the necessary requirements as to attendance, &c., on the courses of instruction in the subjects of examination. Candidates who have passed Part I. of this examination may present themselves for Part II. at the close of the fifth year, provided that they have fulfilled the necessary requirements as to hospital attendance on the various clinical courses in the subjects of examination. Parts I. and II. may be taken together at the close of the fifth year. Attendance on a course in any subject of the Fourth Medical Examination shall not entitle a student to a certificate of attendance unless he has passed in the subjects of the Second Medical Examination.

Degrees of M.D., M.Ch., and M.A.O.—These degrees are not conferred until the expiration of at least three academic years, or in the case of graduates of the University in Arts or Science of at least two academic years, after admission to the primary degrees in the Faculty of Medicine. Every candidate must show that in the interval he has pursued such courses of study, or been engaged in such practical work as may be prescribed. These degrees may be conferred by the Senate either (*a*) after an examination, which includes written, oral, clinical, and practical examinations; or (*b*) on the submission of a thesis or other evidence of original study or research, to be approved by the Faculty of Medicine after an oral or other examination of the candidate on the subject.

The Medical School.—The Donald Currie Chemical Buildings contain a lecture theatre, a preparation room, a chemical museum, a large class-room for elementary practical chemistry, laboratories for qualitative and quantitative analysis, rooms for water and gas analysis, dark room for photographic purposes and balance room, provided with all modern appliances. The Anatomical Department contains a large and well-lighted dissecting-room, a lecture-room, a professor's and demonstrator's room, a bone-room, and a laboratory for microscopic and photographic work. The Medical Museum is in the same building. The Jaffé Laboratories for Physiology comprise a lecture theatre, laboratories for practical work in chemical physiology, histology, and experimental physiology, and in addition small private research rooms, including balance, galvanometer, and centrifuge rooms. The J. C. White laboratories, recently founded, are fully equipped for research in biochemistry and bacteriology. The Musgrave Pathological Laboratory.—In this department opportunity is afforded for research in pathology and bacteriology. The department is in touch with most of the hospitals in Belfast, and there is an ample supply of material for investigation by graduates in morbid histology, clinical pathology, and the bacteriology of infectious diseases. A course in pathology or bacteriology is given to graduates, and members of this class have an opportunity of seeing the methods employed in the various investigations carried out in the department for the Public Health Committee of the Corporation in connexion with water-supply, sewage disposal, meat- and milk-supply, and the diagnosis of cases of infectious diseases. The certificate issued to members of the class in bacteriology qualifies for the D.P.H. degree. The Pharmaceutical Laboratory is fitted and equipped for the work of practically instructing students in the compounding and dispensing of medicines.

Clinical Instruction.—The following institutions are recognised by the University as affording proper opportunities for clinical instruction: the Royal Victoria Hospital, the Mater Infirmorum Hospital, the Union Hospitals, the Belfast Hospital for Sick Children, the Belfast Maternity, the Ulster Hospital for Women and Children, the Ulster Eye, Ear, and Throat Hospital, the Belfast Ophthalmic Hospital, the Purdysburn Fever Hospital, and the Belfast District Lunatic Asylum. Complete information can be obtained from the respective Secretaries.

ROYAL VICTORIA HOSPITAL, Belfast, 436 beds.—Students eligible for McGrath, McQuitty, Malcolm, Coulter Smyth and Elwood Scholarships aggregate annual value £185. Twelve House Surgeons and House Physicians. Thirty-six resident pupilships, three months each, annually for Senior Students, of which a proportion is allotted to Women Students, Special Departments for Radiology, Clinical Pathology, V.D., Dermatology, Gynæcology, Vaccine Therapy, Electrocardiography, *Dentistry*, *Radium Therapy*.

MATER INFIRMORUM HOSPITAL, Belfast.—This hospital contains 270 beds and is open at all hours for the reception of accidents and urgent cases. Clinical instruction is given daily by Physicians and Surgeons. Surgical operations are performed daily. The out-patient departments in Medicine and Surgery, also the special dispensaries for Gynæcology, Ear, Eye and Throat, Electrotherapeutics, Venereal Diseases are very largely attended and afford valuable opportunities to students for the study of those subjects. A House Physician and two House Surgeons are elected every six months. Resident pupils are admitted as the vacancies arise. Three Exhibitions and a Gold Medal are competed for annually in June. Certificates of attendance upon this hospital are recognised by all the Universities and licensing bodies in the United Kingdom.

BELFAST INFIRMARY AND HOSPITAL (1600 beds).—Clinical courses are given quarterly, and a course for D.P.H. in Hospital. Intern Venereal Clinic in Infirmary under Corporation scheme. Maternity Hospital recognised for Practical Midwifery training. Particulars may be obtained on application to the Hon. Sec. Visiting Medical Staff. Certificate of vaccination class recognised by Local Government Board. There is a department for Cancer with 32 beds, and X Ray and Bacteriological Departments.

THE BELFAST HOSPITAL FOR SICK CHILDREN, Queen-street (45 beds).—Clinical instruction is given in this hospital. During the Winter Session two Courses of Lectures are delivered on the Medical and Surgical Diseases incidental to Infancy and Childhood. Demonstrations in Ophthalmology and Pathology are given, and ample opportunities are afforded in the wards and in the Out-patient Department for gaining a practical and theoretical knowledge of the diseases of Infancy and Childhood. This Hospital grants Certificates in Diseases of Children, which are recognised by the various Examining Bodies. Certificates are also granted for post-graduate study. A Gold Medal is offered for competition at the close of the session.

MATERNITY HOSPITAL, Townsend-street, Belfast.—Twenty-five beds in constant occupation, and exclusively *devoted to Midwifery and Antenatal conditions.* There is also a large district. The Queen's University of Belfast have erected a Students' Hostel in connexion with the Hospital where six Students and Post-graduates are received each month. The University Tutor in Obstetrics resides in the Hostel and Students conduct their cases under his supervision. There is a large Antenatal Department and a Department for Venereal Diseases. Communications should be made to the Hon. Secretary of the Medical Staff.

ULSTER HOSPITAL FOR CHILDREN AND WOMEN, Templemore-avenue, Belfast (58 beds).—Clinical instruction to students in Diseases of Children, Gynæcology and Obstetrics. Special departments: Radiology and Actinotherapy, Eye, Ear, and Throat, V.D. Clinic and Antenatal Clinic. Gold Medal awarded annually. Two House Surgeons appointed from students of hospital.

BENN ULSTER EYE, EAR AND THROAT HOSPITAL, Clifton-street (30 beds), and BELFAST OPHTHALMIC HOSPITAL, Great Victoria-street (30 beds).—Practical demonstrations by the staff and occasional clinical lectures in the subjects of Ophthalmology, Otology, and Laryngology. Clinical instruction is given daily.

BELFAST FEVER HOSPITALS.—City Fever Hospital, Purdysburn (300 beds); Union Fever Hospital (200 beds). Clinical Classes are held during the winter and summer sessions. Post-graduate (D.P.H.) Classes are also held. Dr. A. Gardner Robb, Lecturer and Medical Superintendent.

BELFAST MENTAL HOSPITAL (PURDYSBURN VILLA COLONY) (1300 beds). University Lectures and Clinics.

IRISH MEDICAL CORPORATIONS GRANTING DIPLOMAS.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND AND ROYAL COLLEGE OF SURGEONS IN IRELAND.

The Irish Conjoint Board requires of candidates the passage either of its own preliminary examination in the subjects of general education or proof that the candidate has passed one of the tests accepted by the General Medical Council as well as passing in the Pre-Registration Examinations in Chemistry and Physics and Biology.

Professional Examinations.—There are three professional examinations, the first of which cannot be passed earlier than the end of the second winter session, nor the final before the conclusion of full five years of medical study. Before being admitted to *any of them* the candidate must show that he has studied the different subjects in practice and theory for the requisite periods, certificates to this effect being accepted from the authorities of most of the recognised medical schools at home and abroad. The first examination deals with (*a*) Anatomy, and (*b*) Physiology and Histology. The second examination deals with (*a*) Pathology, (*b*) Materia Medica, Pharmacy, and Therapeutics and Ophthalmology, *and may be taken separately.*

Final Examination.—This is divided into three divisions, which cannot be completed until at least five years have passed in medical studies other than those for the Pre-Registration Examinations, and five years at least since the beginning of the curriculum. The divisions are (*a*) Medicine, including Fevers, Mental Diseases, and Diseases of Children; (*b*) Surgery, including Operative Surgery; (*c*) Midwifery, including Diseases of Women and Children, and the Practice of Vaccination.

Diploma in Psychological Medicine.—There are two examinations in connexion with this Diploma: Part I. consists of (*a*) Anatomy and Physiology of the Nervous System; (*b*) Psychology. Part II.: (*a*) Neurology, including Clinical and Pathological Neurology; (*b*) Psychological Medicine, including its legal relationships.

Further information can be obtained from the Secretary of the Committee of Management, Royal College of Surgeons, St. Stephen's Green.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND.

The College issues its Licences in Medicine and in Midwifery to practitioners whose names appear on the Medical Register of the United Kingdom.

The Licence in Medicine.—The subjects of examination are: Practice of Medicine, Clinical Medicine, Pathology, Medical Jurisprudence, Midwifery, Hygiene, and Therapeutics.

The Licence in Midwifery.—Candidates must produce certificates of registration. A registered medical practitioner of five years' standing may be exempted from the examination by printed questions.

The Membership.—Examinations for Membership are held in February, June, and November.

The Fellowship.—Fellows are elected by ballot. Applicants must have been a Member of the College for at least one year and must have attained the age of 27 years.

Further particulars can be obtained from the Registrar of the Royal College of Physicians of Ireland, 6, Kildare-street, Dublin.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

The College issues its Licence in Surgery to practitioners whose names are entered either on the Medical Register for the United Kingdom, the Colonial Medical Register, or the Foreign Medical Register of the year in which he presents himself for examination, and who satisfies the Council that he has passed through a course of study and Examinations equivalent to those required by the Regulations of the Irish Conjoint Board.

Candidates are examined in General Surgery (paper and oral), Clinical Surgery, Surgical Pathology (oral), Operative Surgery, Surgical Anatomy (paper), and Ophthalmic and Aural Surgery (clinical).

Diploma in Midwifery.—A diploma in Midwifery is granted after examination to persons possessing a registrable qualification.

Fellowship Examinations.—Candidates for the Fellowship shall make application to the President and Council to be admitted to examination. They are required to pass two examinations—Primary and Final. Candidates may present themselves for the Final Examination immediately after passing the Primary part, provided they have complied with the necessary regulations. The subjects for the Primary Examination are (*a*) Anatomy, including Dissections; and (*b*) Physiology and Histology. The subjects for the Final Examination are Surgery, including Surgical Anatomy and Pathology. For admission to the Final Examination the candidate must have passed the Primary Examination, and must be a Licentiate or Graduate in Surgery of a university or licensing body recognised by the General Medical Council; all such candidates must not be less than 25 years of age.

Further particulars can be obtained from the Registrar of the College, Stephen's-green West, Dublin.

ROYAL COLLEGE OF SURGEONS IN IRELAND (SCHOOLS OF SURGERY).—The schools of surgery are attached by Charter to the Royal College of Surgeons and have existed as a department of the College for over a century. They are carried on within the College buildings and are specially subject to the supervision and control of the Council, who are empowered to appoint and remove the professors and to regulate the methods of teaching pursued. The buildings have been reconstructed, the capacity of the dissecting-room nearly trebled, and special pathological, bacteriological, public health, and pharmaceutical laboratories fitted with the most approved appliances in order that students may have the advantage of the most modern methods of instruction. The entire building is heated by hot-water pipes and lighted throughout by the electric light. Winter Session commences in October; Summer Session in April. Scholarships and Prizes; Carmichael Scholarship, £15; Mayne Scholarship, £8: *Stoney Memorial gold medal*; *Operative Surgery*, gold and silver medals; Piercfoy Memorial Prize, value £150; Barker Prize, £26 5*s.*; H. Macnaughton-Jones gold medal in Obstetrics and Gynæcology; and class prizes and medals. Prospectuses and guide for medical students can be obtained post free on written application to the Registrar, Royal College of Surgeons, Stephen's-green W., Dublin.

APOTHECARIES' HALL OF IRELAND.

The Licence of this Hall is granted to students who present certificates of having fully completed the course of study as laid down in the curriculum and who pass the necessary examinations. The diploma of the Hall entitles the holder to be registered as a practitioner in medicine, surgery, and midwifery, with also the privileges of the Apothecary's Licence.

Candidates must pass two Professional Examinations, called the Primary Examination and the Final Examination, which are conducted at separate times, partly in writing, and partly practically and orally. The Primary and Final Professional Examinations are held twice a year—viz., in June and November, or such other dates as may be determined.

Candidates who produce satisfactory evidence of having passed an examination for a Degree or Licence in Medicine, conducted by any University or Royal College in the British Empire, or by any Foreign University whose Degrees are recognised in the Foreign List of the Medical Register, will be exempted from the Primary Examination.

The subjects for Part I. of the Primary Examination are: Anatomy, Physiology and Histology, including Bio-Chemistry; and for Part II., Materia Medica and Pharmacy, Pathology, and Medical Jurisprudence and Hygiene.

For the Final Examination the subjects are: (*a*) Medicine and Clinical Medicine and Clinical Methods. (*b*) Surgery—Clinical, Ophthalmic and Operative; and Surgical Anatomy. (*c*) Midwifery and Gynæcology, and Practical Pharmacy and Materia Medica (if not taken at Intermediate Examination).

Each candidate before receiving his diploma must produce evidence that he has attained the age of 21 years. The details of the course of education required and syllabus of the examinations will be supplied by the Registrar at 95, Merrion-square, Dublin.

WE take this opportunity of thanking the officials of Government Departments and the Deans and Secretaries of the various institutions for their kind coöperation in enabling us to bring the information contained in our Students' Number up to date.

THE LANCET.

NDON: SATURDAY, AUGUST 31, 1929.

HYSIOLOGY AND THE MEDICAL CURRICULUM.

an issue devoted to considering the training of who are entering the medical profession, while ain information will bear relation to the curri- which they have to follow, some reflections the general circumstances of the medical career ertinent. During the year that has passed the last issue of the Students' Number alling of medicine has been in no way aly altered either in relation to the train- f students or in relation to their future sional prospects. The medical curriculum been unaltered since its inter-arrangement year following the resolution of the General al Council passed some seven years ago; the rowded schedules of study have been somewhat by the introduction of order, while the spirit by the licensing bodies when various details under discussion is of good omen for future es. And changes there must be both in the mic and the practical equipment of doctors in athy with the growth of professional knowledge, with the increasing intimacy between medicine rticular and science in general. The professional rtunities remain as good and as numerous as ofor, but the difficulties of the medical career t be said to have abated in any marked way. it is gratifying to be able to say that the rtunities, because of their vast implications, eigh the disadvantages. It is with the full ledge that the life of the doctor is a finer career over, because of the far-reaching and well-orted promises of good which the development of cine are giving, that we welcome into our ranks ecruits who will take their places next October o schools.

e anticipation that the studies preliminary to dical course, as well as those directly connected that course may always need variation is justified he proceedings before the Section of Physiology Biochemistry of the British Medical Association h we publish in another column. Prof. F. R. SER, in opening a discussion on the place which an physiology should occupy in the training of cal students, spoke exactly words which ought to ppreciated alike by the medical profession and the ic that it serves, and indicated an aspect of ical teaching whose importance will be seen readily. pointed out that human physiology must largely ern itself with the interaction of systems, and that ledge of it means comprehension of human stments to environment, the great responsibility edicine being to ascertain the causes of mal- stments, in order to remove or mitigate results. This view of the study of physiology introduces the question of how much should be taught to the medical student and at what place in his curriculum. All will agree that human physiology should be taught to the students before admission to the wards, but how much of what may be termed the science of living is it possible to impart while formal instruction is still being given in the processes of, say, the respiration and the circulation? The more the student has a chance of enlarging his knowledge of normal man before being introduced to the abnormalities of injury and disease, the easier will it be for him to appreciate human adjustments, and therefore to follow with intelligence the teaching of the clinicians who are his preceptors in the wards. Says Sir GEORGE NEWMAN, in his Annual Report for the Year 1928, as Chief Medical Officer of the Ministry of Health, which has just appeared (see p. 480): "There must be a standard in our minds, and that standard should not be one of disease or pestilence, but of health and physiology. It is true there is no fixed line of health for a nation any more than for an individual. But we must formulate an average, a norm, as best we may, establishing it on physiological facts. . . . Out of our rapidly extending knowledge of physiology and anthropometry we must build up a normal conception of body size, weight, and height, body temperature, the pulse-rate, blood pressure, the respiration-rate, lung capacity and chest expansion, muscle output, nerve efficiency, sense faculty, and mental tests. We must aim to bring the race, by means of the individual, steadily towards this standard." In these words we have a fine confirmation of Dr. FRASER'S thesis, and, further, an eloquent plea for an altered attitude towards the training of medical students in human physiology. And evidence in the same direction is contained in the pithy notes of Dr. G. F. WALKER, of Leeds, who writes in another column (see p. 481) out of his experience as medical tutor at the University. That changes in the indicated direction have already been made quietly and with success in certain schools shows that we have here no drastic measure of reform to clamour for, but only such an inter-arrangement of work as has already taken place along many other lines.

And the influence of such a modified curriculum should have wide-reaching effect. Human physiology is to-day becoming a study of real public interest, while in State, private, and public schools alike it is now felt that a knowledge of the fundamentals of biology should be in the possession of all. It is easy to see that with a public thus growing up to familiarity with normal standards, the doctor will find it far easier to obtain a comprehension of his efforts, of his difficulties, and, perhaps, of his successes when dealing with the variations of and divagations from the normal which constitute disease. But it is necessary, for his counsel to have prompt appeal, that he himself should understand the normal circumstances from which a default has occurred. Undoubtedly the plea made in the Section of Physiology and Biochemistry that more attention should be paid to the normal in the earlier stages of medical education is a forcible one. When this happens and when at the same time the public, in accordance with a routine upbringing, acquire also a knowledge of normal biology, a great deal of unnecessary dissension between the medical profession and the public will be abated, a quickening of public interest in the organisation of our calling will follow, and we shall witness more prompt manifestations of willingness on the part of the public authorities to use medical service intelligently.

The Medical Services.

ROYAL NAVAL MEDICAL SERVICE.

CHOOSING A CAREER.

THERE always have been, there are now, and there always will be a certain number of young medical men to whom life in the Royal Navy appeals more than does any other life of a medical man. The type referred to is the man who may have been brought up in Naval surroundings, he may have Naval relations, or he may just love the sea. To a man of this temperament a career as a Medical Officer in the Royal Navy offers very definite attractions. In these days his professional knowledge will most certainly not rust anywhere; but especially in the Naval Hospitals will he have opportunities of practising every branch of his profession, except, of course, diseases of women. He can obtain one of the 60 paid specialist appointments. These include medicine, surgery, diseases of the eyes, diseases of nose, ear and throat, radiology, anæthetics, genito-urinary and venereal diseases, physical training, bacteriology, pathology, and hygiene. He will be encouraged to work hard and play hard. He will see the world under ideal conditions, because wherever he goes he will be a welcome guest, as is always the case with those who are privileged to wear the King's uniform.

In any walk in life success and happiness depend primarily on two main conditions. You must like your fellow men and they must like you.

The right type of man for a Naval Medical Officer is a good doctor, keen on his work and keen on his play, unselfish and a gentleman.

If the doctor is of this type he is invariably everybody's friend. The Naval Officer and the blue-jacket are quick to recognise a Medical Officer who is keen on his work, thoughtful of his patients, and one who strives after improving the health of the Navy. Such a Medical Officer finds life agreeable as everyone is ready to befriend him, and nowhere can one find more delightful friends than in the Navy.

To help men to take higher qualifications opportunities are given, when the exigencies of the Service will permit, for medical officers to take post-graduate courses prior to sitting for these higher examinations. A large number of Naval Medical Officers since joining the Navy have taken qualifications such as M.D., F.R.C.S., M.R.C.P., D.P.H., D.T.M., and D.O.M.S., &c. It is recognised that this is good for the Navy and good for the officer himself.

Work of the Naval Medical Service.

In our large Naval Hospitals the medical, surgical, and specialist work is of a very high standard. The work is very exacting, and it is the aim of the Admiralty to arrange appointments a far as possible so that medical officers have an opportunity of alternating their work, not only at home and abroad, but also ashore and afloat.

To give Naval Surgeons opportunities for professional work has always been a very definite policy of the Admiralty, and within the last year or so this matter has received still further attention.

The General and Specialist Courses have been increased so that, as far as possible, every officer shall have a course of instruction of not less than four months' duration every four years. The number of specialists allowed is now 60 instead of 46 and the specialist allowance is 5s. a day instead of half-a-crown a day. The establishment of Surgeon-Captains has been increased from 16 to 20.

The total number of Medical Officers in the Navy is about 400, and every recent improvement has been made towards giving increased opportunities of advancement and accelerated promotion to the best men.

The advantages of a career with its period of strenuous clinical work, followed by a period of comparative leisure which can be devoted to study, &c., are laid stress on in the Presidential Address of the War Section of the Royal Society of Medicine delivered on Oct. 10th, 1927.

The work and professional opportunities of the Service Medical Officer are described, but the address is necessarily brief, and it is only by reading between the lines that one can really visualise the field for work which lies before the keen Naval Doctor.

Not only has he this purely medical work to interest him. He has opportunities to emulate some of the great Naval Surgeons of the past such as Darwin, Huxley, and many others, who have contributed so much to science.

Play in the Navy.

Recreation is a vital part of the Navy, and there is no branch of athletics or field sports in which the Naval Officer does not have an opportunity of trying his hand. Not only is the champion encouraged but also the less proficient.

In every home port and on most foreign stations there are opportunities for football, cricket, tennis, golf, rowing, sailing, swimming, and all other sports. On some foreign stations the Naval Officer can get shooting and riding in plenty; and so cheap that he can indulge in them on his pay alone. In civil life at home only a rich man could get such magnificent shooting as the Naval Officer does is some parts of the world.

Pay.

The cost of living in the Navy is cheap, and an officer can live on his pay and enjoy life if he is not extravagant, especially if he does not embark in matrimony too early. A small amount of private means goes much further in the Navy than in civil life. The three vital points—pay, prospects, and promotion—of the naval medical officer can be grasped by referring to the following clear and brief table.

FULL PAY.

		£	£	
SURGEON LIEUTENANT (short service and permanent service)	from	452 to	499	per annum
SURGEON LIEUTENANT - COMMANDER (promoted after six years' service)..	"	600 to	636	"
SURGEON COMMANDER (promoted after a further six years' service)..	"	772 to	976	"
SURGEON CAPTAIN (promoted by selection)	"	1110 to	1372	"
SURGEON REAR-ADMIRAL (promoted by selection)		1800		
MEDICAL DIRECTOR-GENERAL (Surgeon Vice-Admiral) ..		2350		

Allowances.

An outfit allowance of £50 towards cost of uniform is given.

Allowances when in charge of hospitals and sick-quarters ..	10s. and 5s. per diem.
Sixty Specialist allowances of ..	5s. per diem.
Allowances to Senior Medical Officers in flag ships ..	5s. and 2s. 6d. per diem.

Accelerated promotion can be gained under certain conditions; provision allowance and lodging allowance are paid when victualling and accommodation are not provided. Servants allowance is also payable in certain appointments.

The extra allowances alluded to in this table are not to be looked upon as very exceptional. About a quarter of the Medical Officers of the Navy are drawing extra allowances.

Pension.

Finally as regards pensions, is there any man in practice, panel or otherwise, who can say to himself with certainty, "I shall retire at the age of 50 with a life-long pension of £564 per annum for myself, and a pension for my wife should she survive me"? Obviously there are very few. Remember, too, that at the age of 50 a medical man is still young and full of work, and after some of the various specialist appointments he may have held in the Navy, he will be able to hold his own with his confrères on shore and start anew in any of the big centres of the country. His assured income helps him to carry on until his practice is established.

PENSION.

	Maximum retired pay.
SURGEON VICE-ADMIRAL ..	£1123 per annum, on vacating office.
SURGEON REAR-ADMIRAL ..	£950 per annum, at age of 60.
SURGEON CAPTAIN	£846 " " 55.
SURGEON COMMANDER	£564 " " 50.
SURGEON LIEUTENANT-COMMANDER AND SURGEON LIEUTENANT	£423 " " 45.

Officers permitted to withdraw receive gratuities on the following scale:—

	£
After 4 years' full pay permanent service ..	500
" 8 " " " " ..	1000
" 12 " " " " ..	1500
" 18 " " " " ..	2250

Of recent years Medical Officers have been admitted into the Navy without entrance examination, and for short service, with the option of turning over to the permanent service, but it is anticipated that it will not be long before the Admiralty will revert to the old established system of entrance by competitive examination twice a year, in batches of about ten officers.

The Medical Director-General of the Navy, Queen Anne's Chambers, Tothill-street, London, S.W.1. would be glad to receive inquiries from prospective candidates.

DENTAL BRANCH.

The Naval Dental Service offers similar opportunities to qualified dental surgeons except that higher rank than that of the recently instituted Surgeon Captain (D) is not open to them. They are provided with suitable surgery accommodation equipped with modern appliances and supplied with all material required for their work, and there is every opportunity for them to maintain a high standard of professional skill.

Candidates are required to produce certificates of birth, registration, and of character, and must be physically fit for active service anywhere. An outfit allowance of £50 is payable to officers finally entered and commissioned. The rank of Surgeon Lieutenant-Commander (D) is attained on the completion of six years' satisfactory service. Promotions to Surgeon Commander (D) and Surgeon Captain (D) are made strictly by selection from the rank next below and are confined to officers who prove fitted in every respect for these ranks. The present establishment of dental officers is: 1 Surgeon Captain (D), 3 Surgeon Commanders (D), 60 Surgeon Lieutenant-Commanders (D) and Surgeon Lieutenants (D).

Provision has been made for candidates who, at the time of passing the examination, hold or are about to hold an appointment as Dental Officer in a recognised Civil Hospital. The time concerned, provided it does not exceed six months, may reckon for increase of full pay while on the active list. Surgeon Lieutenant-Commanders (D) of over two years' seniority will be eligible for a three months' Post-graduate Course while borne on full pay.

On the completion of two years' service in the rank of Surgeon Lieutenant-Commander (D), dental officers on the Active List are eligible for a three months' post-graduate course at a dental hospital and school at the public expense, and will draw full pay while attending the course.

Pay.—The current rates of full pay for Dental Officers are as follows:—

	£ £
Surgeon Lieutenant (D)	377–402
Surgeon Lieutenant-Commander (D) (promoted after six years' service)	650–687
Surgeon Commander (D) (promoted by selection to fill vacancies in Establishment)	730–933
Surgeon Captain (D) (promoted by selection to fill vacancy in Establishment).. ..	1073–1329

The Regulations regarding Pension and Withdrawal Gratuities are the same as for Medical Officers in the corresponding Ranks.

As in the case of the medical branch, 20 per cent. of the rates of full pay, unemployed pay, half pay, and retired pay introduced in 1919 is considered as due to the high cost of living in 1919 and subject to change periodically either upwards or downwards according as the cost of living rises or falls. The first revision took place in July, 1924, when all the rates were reduced by approximately 5½ per cent., the second revision took place in July, 1927, when all rates were reduced by ½ per cent., and further revisions are due every three years—i.e., in July, 1930, and so on.

ARMY MEDICAL SERVICE.

ROYAL ARMY MEDICAL CORPS.

THE publication of the Royal Warrant of 1926 has removed many of the grievances of officers of the Corps, and this Service can again be recommended as a career to young medical men. Competitive examinations for regular commission, which have been in abeyance for some time, will again be held half-yearly in January and July. These examinations in medicine and surgery are entirely of a clinical and practical character, partly written and partly oral.

The regulations for admission giving full details should be obtained from the Permanent Under Secretary of State (A.M.D. 1), War Office, Whitehall, London, S.W. 1, and carefully studied. A personal interview with a representative of the Director-General, Army Medical Services, is readily obtainable.

The rates of pay and allowances are good; the opportunities of post-graduate study are generous, and the work is varied, responsible, and interesting. The gratuities after certain periods of service enable an officer should he so desire to leave the Service with a capital sum large enough to go a long way towards re-establishing himself in civil life, and, further, the knowledge of the world and the comradeship of his fellow officers that he has gained in the Army will be of no small value to him.

New entrants are commissioned in the rank of Lieutenant, and the first six months of service are spent on probation, during which time they undergo, in addition to their Military training at the Royal Army Medical Corps Depôt at Aldershot, a probationary course at the Royal Army Medical College in London in Hygiene, Pathology, Tropical Medicine, Military Surgery, Recruiting, the prevention and treatment of Venereal Disease, and the elements of Army Administration. At the end of this course, and after qualifying at the necessary examinations, their commissions are confirmed, and they take their places in seniority according to the total marks obtained at all examinations up to that date. Officers Training Corps service with possession of Certificates "A" or "B" (Medical) carry a definite value in marks in this total.

An entrant who is holding or about to hold at the time of the entrance examination a resident House Appointment at an approved Civil Hospital may be seconded while holding such an appointment up to a maximum period of 12 months. A candidate who has held such an appointment within six months of entry may be granted an antedate up to 12 months in respect of the period the appointment was held. This secondment and antedate counts in all respects as commissioned service, except that pay will not be issued for that period.

After a total period of one year's service at home the young officer goes abroad, probably to India, for his first tour of foreign service. Here he gains his first practical experience of tropical disease and tropical hygiene, and possibly his first experience of active service on the frontiers of India. His tour abroad lasts five years, with probably six months' leave home during that time. On returning home the R.A.M.C. officer has the opportunity to decide whether he will remain in the Corps or accept the gratuity of

£1000 after seven years' service, and try his fortune in civil life. If he elects to remain, he will, between his eighth and twelfth year of service, undergo a course of post-graduate study at the Royal Army Medical College and the London Hospitals of five months' duration, followed by a course of study of a special subject selected by himself, provided he has shown special aptitude in the post-graduate course or during his previous service. During this period of study he remains on full pay, and the fees for the courses are paid by the State. When qualified in his special subject, the officer becomes entitled to specialist pay at 5s. per day when holding a specialist appointment. After this post-graduate course the officer probably proceeds abroad again and promotion to Major rapidly ensues, and from that time onward the officer receives regular successive increases of pay, and is eligible for additional and charge pay as well. The Directorates of Hygiene and Pathology and the appointment of two serving officers as Consultants in Medicine and Surgery have been instituted and have proved a marked success, all these appointments being of the rank of Colonel or Major-General.

Under these conditions the possibilities for good workers are very great in the Royal Army Medical Corps. There is scope for original research in tropical disease, in preventive medicine, and in bacteriology, as well as in the large clinical field open to the specialist in Medicine, Surgery or Gynæcology, in Venereal Disease, and in Ophthalmology. Child welfare is also undertaken systematically by officers of the Royal Army Medical Corps.

At the same time instruction in administration is continuous. The Royal Army Medical Corps is essentially organised for war, and one of the lessons of the Great War was that trained administrators must exist to enable the fullest benefit to be obtained from professional talent. Many appointments carrying administrative responsibility are open to those officers who display capacity for this duty. All officers must be prepared to undertake command and to have a knowledge of Army administration, especially in war. Equally important is the technical training of the Non-commissioned Officers and men of the Corps in such "trades" as Trained Nurse, Nursing Orderly, Masseur, Radiographer, Operating Room Assistant, Laboratory Assistant, Hospital Cook, Dispenser, &c. This training is carried out by the Officers and Nursing Sisters, and opens a large field for those who have ability in lecturing and teaching as well as the power of influencing men.

Promotion.

Promotion takes place automatically to Captain after 3½ years, and to Major after 12 years' service, provided the officer is qualified and recommended for promotion. Promotion to the higher ranks is by selection from those senior in the rank below, but special promotion by brevet or otherwise is open to officers of the Royal Army Medical Corps.

* Pay Warrant rates as amended by A.O. 196/26 less 6 per cent. from July 1st, 1927, vide A.O. 1 of 1927. The Pay Warrant rates are subject to revision to an extent not exceeding 20 per cent. according to variation in the cost of living. The next revision takes place from July 1st, 1930.

† Rates of allowances vary from time to time and issues are subject to conditions laid down in the Allowance Regulations.

Additional Pay and Charge Pay for R.A.M.C. Officers.

(1) Officer not above the rank of lieutenant-colonel, while acting as specialist in a post considered by the Army Council to merit the grant of additional pay, according to subjects or groups of subjects as under.

Operative Surgery, advanced; Medicine; Ophthalmology; Gynæcology and Midwifery; Dermatology and Venereal Disease; Otology, Laryngology, and Rhinology; Radiology; Anæsthetics; Mental Diseases; Hygiene; Pathology; *subjects other than above, at the discretion of Our Army Council*, 5s. daily.

(2) (*a*) Officer in charge of a hospital.—If the number of equipped beds, as certified by the Deputy Director of Medical Services, exceeds—

50 beds ..	2s. 6d. daily.	300 beds ..	7s. 6d. daily.
150 ,, ..	5s. 0d. ,,	500 ,, ..	10s. 0d. ,,

Officer in charge of a medical or surgical division of a general hospital with not less than 300 beds—half the above rates.

	Daily. *s.* *d.*
(*b*) Senior medical officer, Royal Arsenal, not exceeding	10 0
(*c*) Officer in command of the depôt, Royal Army Medical Corps	5 0
(*d*) The senior officer of the Army Medical Services with an army in the field: A rate to be fixed by the Army Council according to the magnitude of the charge.	
(*e*) The officer, if under the substantive rank of colonel, holding the appointment of senior medical officer in a command abroad, or of assistant director of medical services, if the number of soldiers is 1500 or upwards	5 0
(*f*) Adjutant R.A.M.C. Depôt	5 0
(*g*) Adjutant R.A.M.C. (Territorial Army)	2 6

Retirement and Retired Pay.

The following are the rates of retired pay:—

1. Retired pay will consist of two parts: (*a*) a service element based on the officer's total service; (*b*) a rank element for the rank from which the officer retires. An officer with less than 20 complete years' service will not be eligible to retire voluntarily on service retired pay.

2. The scale will be as follows, subject to the reduction of 6 per cent. referred to below:—

(a) Service element.—£15 a year for each completed year of service as a medical officer.

(b) Rank element.—

Rank from which retired.	After completing 1 year's service in the rank.	After completing each additional year's service.	Maximum rank element.
	£	£	£
Major	12	12	120
Lieutenant - Colonel	150	30	240
Colonel	290	50	390
Major-General ..	440	50	540
Lieutenant - General	590	50	690

The retired pay of an officer retiring with less than one complete year's service in the rank from which he retires will be assessed as though he had retired from the rank below.

Maximum rates of retired pay (a) and (b) together:—

	£		£
Captain and Subaltern ..	300	Colonel	800
Major	450	Major-General ..	1000
Lieutenant-Colonel ..	600	Lieutenant-General	1200

The above rates are those laid down in the Pay Warrant. They have been reduced by approximately 6 per cent. as from July 1st, 1927, and are subject to future variation with fluctuation in the cost of living.

3. Officers with seven and less than 20 years' service as medical officers may be permitted to retire with a gratuity in accordance with the following scale:—

After 7 years' service as a medical officer.. ..	£1000
„ 15 „ „ „ ..	£2800
„ 18 „ „ „ ..	£3500

THE ARMY DENTAL CORPS.

The Corps is administered by the Director-General, Army Medical Services. It is a joint service for the Army and Royal Air Force, and personnel is required to serve under either force and be interchangeable. Officers and other ranks posted for duty with the Royal Air Force will perform their duties under the Regulations of the Royal Air Force for the employment of dental personnel, but the conditions in the following tables apply equally in either force. Promotion is carried out on one general list. Regulations for admission to the Army Dental Corps should be obtained from the Under-Secretary of State, War Office, and carefully studied.

OFFICERS: *Appointment and Promotion.*

1. Commissions as Lieutenants in the Army Dental Corps may be given to persons duly qualified under regulations approved by the Army Council.

2. An officer who is commissioned after holding a whole-time appointment in a recognised civil dental hospital or in the dental department of a recognised civil general hospital for a period of not less than six months, may be granted an antedate covering the period of his appointment, but not exceeding six months, provided that the interval between the termination of the hospital appointment and the date of entry into the Service shall not ordinarily exceed six months. The period of such antedate will reckon towards promotion, increase of pay, gratuity or pension.

3. An officer is eligible for promotion to the rank of Captain on completion of three and a half years' service and to the rank of Major on completion of 12 years' service in the Corps, provided he has previously qualified in such manner as may be prescribed by the Army Council.

4. Promotion to the rank of Lieutenant-Colonel and Colonel to fill the establishments laid down from time to time for those ranks shall be made by selection of the Army Council, provided the officer has previously qualified for promotion to those ranks in such manner as may be prescribed by the Army Council.

Pay.

The following are the rates for officers of the Army Dental Corps.

These rates are 6 per cent. below those shown in the Pay Warrant, 1926, as amended by Army Order 190/26. The latter are subject to revision to an extent not exceeding 20 per cent., according to variation in the cost of living. The next revision takes place on July 1st, 1930.

	Per diem.		
	£	s.	d.
Lieutenant	0	18	10
Captain	1	3	6
Captain, after 8 years' total service	1	6	4
„ 10 „ „ „	1	8	2
Major	1	12	10
Major, after 15 years' total service	1	17	8
„ „ 18 „ „ „	2	0	0
„ „ 20 „ „ „	2	4	8
Lieutenant-Colonel	2	11	8
Lieutenant-Colonel after 3 years' service as such	2	16	4
Colonel	3	8	6

Charge Pay.

The officer in charge of the Dental Laboratories, Aldershot, receives charge pay at the rate of 5s. a day if holding the rank of Captain, or 2s. 6d. a day if holding the rank of Major.

Allowances.

The allowances for officers of the Army Dental Corps are at the same rates as for officers of the Royal Army Medical Corps.

Retirement and Retired Pay or Gratuity.

(1) The rates of retired pay will be the same as for officers of the Royal Army Medical Corps.

(2) Voluntary retirement on retired pay will not be allowed until after twenty years' service.

(3) Earlier retirement on gratuity may be allowed:—

After 8½ years'	service as a Dental Officer,	gratuity of £1000.
„ 15 „		„ £2000.
„ 18 „		„ £3000.

The aim of the Corps is the prevention of wastage on account of dental disease or dental deficiency, and, to enable this to be carried out, every recruit is inspected by a dental officer immediately after joining and all necessary treatment carried out. The soldier is re-inspected at least once a year and his dental efficiency maintained at the best standard possible.

INDIAN MEDICAL SERVICE.

IT is the view of many senior officers in the Service that the period of depression is now passing and that the prospect is again bright for those who are fitted in physique and disposition for a medical career in India. The offer of permanent commissions on specially favourable terms to medical men of European descent who were free to sail forthwith to India met last year with the desired response, and the number of commissions granted during the last twelve months is 30.

But the new outlook involves frank acceptance of the Indian reform scheme, the essential of which is increasing participation of Indian-born subjects in the government of the country, although, so long as Europeans are employed in the various departments of the Indian Civil Service, nothing is more certain than that there will and must remain European doctors to attend them. India definitely requires European assistance, not only for the care of the military and civil European population, but for the maintenance in the country of that spirit of modern medicine which has accomplished already such mighty things, and which day by day is spreading in influence and value.

The Government of India issued a communiqué last year dealing in detail with the reorganisation of the medical services in India. The scheme then sanctioned is based on proposals framed in consultation with local governments. The Indian Medical Service, constituted on the same broad lines as at present, will be retained primarily to meet the needs of the Indian army, and in order to maintain two essential requisites—namely, (1) the necessary minimum war reserve of medical officers, and (2) the provision for European medical attendance on officers and their families.

Local governments in India will be required to employ a stated number of I.M.S. officers. It has been calculated that the war reserve to be employed by the civil side should consist of 134 British and 66 Indian officers, the larger proportion of British officers being due to the fact that they cannot be recruited on emergency in India from the ranks of private practitioners. Medical attendance on British personnel, and the requirements of civil administration, for which the Central Government is still responsible, involve the provision of a number of employments termed "residuary," the incumbents of which must be retained permanently in civil employment, so as to ensure the continuance under any circumstances of a skeleton staff to cope with civil requirements. Further details regarding the posts on the civil side were published in the Students' number of 1928.

Rules forming an integral part of the reorganisation scheme have been drawn up to safeguard the varied interests of the Indian army, the provincial governments, and the medical officers themselves (vide THE LANCET, May 19th, 1928, p. 1028). Under these it has now been ruled that as long as any Indian Medical Officers in civil employ in 1928 remain, the administrative posts will be filled from among them.

Thus the social effect of Indianisation should not press hardly on the medical service for the reason that European doctors will be chiefly requisitioned in stations with considerable European communities. In these communities the equipment and organisation of hospitals has been steadily improving and men with professional ambition will find positions which will satisfy their aspirations. On the military side the station hospital system has rendered the position of medical officers more independent by making teamwork possible and permitting of specialisation in various departments of medicine and surgery. Lastly, those who join now will have unequalled prospect of advancement in a Service which has been so depleted for 10 or 15 years or more, and the terms of service announced by the Secretary of State for India in 1926 assure conditions of pay, pension, and furlough much superior to those previously offered.

The New Regulations.

Competitive examination remains suspended for the present and admission to the Service is on written application to the India Office. As sound bodily health is a first essential candidates may, if they wish it, undergo a preliminary examination by a Medical Board which meets weekly at the India Office.

Candidates must be under 32 years of age at the time of application, and must possess a qualification registered in Great Britain and Northern Ireland, under the Medical Acts in force at the time of appointment. Arising out of the recommendations of the Lee Commission the Secretary of State for India in Council after consultation with the Government of India has decided that the Indian Medical Service constituted on the same broad lines as in the past shall be retained primarily to meet the needs of the Indian Army. In order to maintain the necessary minimum war reserve of military medical officers, and to provide for European medical attendance for European officers of the Superior Civil Services and their families, local governments will be required to employ a stated number of Indian Medical Service officers. The Government of India will draw on the same Service to meet the requirements of the civil administration for which they are responsible. For the present 237 such posts have been reserved, and including the leave reserve will provide employment for 302 officers. 212 of these officers will be British medical men and 90 Indians. As the proportion of European to Indian civil officers diminishes these figures will be subject to periodical scrutiny, and, if [illegible]essary, to revision. It will be a definite condition [illegible] for all future entrants to the Service that ability [illegible] to serve on either the civil or the of influen[illegible] [illegible]fficers are required to perform two years' military duty subsequent to permanent appointment before they can be considered eligible for civil employment. Executive medical officers in both civil and military employment may attend persons unconnected with Government service provided their duty admits of it. On the military side, however, the opportunities for private practice are not great. Service during the war as a medical or combatant officer, or in a position usually filled by an officer, counts towards promotion and pension so long as the rights of officers who have entered by competition are not interfered with.

Rates of Pay.

The monthly rates of pay for European officers of non-Asiatic domicile in the Service are as tabulated below. The rupee, it may be remembered, has now been definitely stabilised at 1*s*. 6*d*.

Rank and service in rank.	Basic pay.	Overseas pay.	Year of total service.
	Rs.	Rs.	
Lieut.	500	150	First
		150	Second
		150	Third
Captain:—			
1. During first three years' service as Captain.	650	150	Fourth
		£15	Fifth
		£15	Sixth
2. With more than three and less than six years' service as Captain.	750	£25	Seventh
		£25	Eighth
		£25	Ninth
3. With more than six years' service as Captain.	850	£25	Tenth
		£25	Eleventh
		£30	Twelfth
Major:—			
1. During first three years' service as Major	950	£30	Thirteenth and over.
2. With more than three and less than six years' service as Major	1100		
3. With more than six years' service as Major.	1250		
Lieut.-Colonel:—			
1. Until completion of 23 years' total service	1500		
2. During twenty-fourth and twenty-fifth years' total service	1600		
3. After completion of 25 years' total service	1700		
4. When selected for increased pay ..	1850		

Note.—Until the completion of 23 years' total service basic pay is regulated according to rank and service in rank (column 1) which, owing to the system of accelerated promotion, may be in advance of the time-scale of promotion. Overseas pay is regulated solely with reference to length of total service (column 4). In addition to the above rates various allowances are admissible for a large number of special appointments on both the military and the civil side which may be held by members of the I.M.S. Special high rates of pay are also attached to the numerous administrative appointments open to officers in both branches of the Service. The appointment of Director-General, I.M.S., which is held by an I.M.S. officer, carries pay of Rs.3500 per mensem. The appointment of Director of Medical Services in India, carrying pay at Rs.3200 per mensem, may also be held by an officer of the Indian Medical Service.

Initial rates of pay are based on the assumption that the majority of newly appointed officers will be bachelors. Officers on arrival in India will be posted for one year to specially selected stations. Officers in military employment, when in command or second-in-command of the larger station hospitals, receive special allowances. On the civil side there are public health, bacteriological, research, and professorial appointments carrying special enhanced rates. Officers on appointment receive an outfit allowance of £50.

Pensions and Allowances.

The rates of pensions are as shown in the table below.

There are additional pensions not subject to the above reduction ranging from £95 to £350 per annum for officers who have held high administrative appointments as colonels or major-generals.

Service.	Rates per annum.	Service.	Rates per annum.
After 17 years ..	£400	After 23 years ..	£620
" 18 " ..	430	" 24 " ..	660
" 19 " ..	460	" 25 " ..	700
" 20 " ..	500	" 26 " ..	750
" 21 " ..	540	" 27 " ..	800
" 22 " ..	580		

Note.—The above rates are subject to revision triennially upwards or downwards, to an extent not exceeding 20 per cent. in all, on account of a rise or fall in the cost of living, as compared with the year 1919. A deduction of 4½ per cent. on this account has already been made. Nevertheless the full pension of a lieutenant-colonel cannot be cut below the maximum of £700 under the old rules in the case of officers who entered the service before July 1st, 1920.

Officers on appointment are provided with free passage to India, normally by transport. The wives and families of officers who are married prior to the date of the officers' embarkation on first appointment will also be given free passage to India. Officers are granted a certain number of return passages home at Government expense during their career. There are special allowances for officers whilst on study leave.

Further particulars can be obtained on application to the Secretary, Military Department, India Office, Whitehall, London, S.W. 1. Letters should be marked "Recruitment for I.M.S."

ROYAL AIR FORCE MEDICAL SERVICE.

THE Air Council attach great importance to attracting into the Service the best type of medical man, since on the capacity of the Medical Service depends in a peculiar degree the safety and efficiency of the Air Force. The duties of a medical officer in the Air Force include not only the prevention and treatment of those ordinary diseases to which the personnel of any fighting service are liable, but the special study of the mental and physical stresses imposed on the airman in diverse circumstances and climates—a new branch of medicine which still provides considerable scope for research.

As promotion to the higher ranks of the Service is by selection from officers who are eligible by reason of length of service, and as a certain proportion of the higher ranks will be reserved for purely professional as opposed to administrative appointments, it will be seen that there are excellent prospects for the young medical officer who exhibits ability and energy in his professional work.

The work to be done, therefore, has a high professional interest which, combined with good rates of pay and allowances, offers a career for medical men which should prove both attractive and interesting. The life is one which is certain to appeal to the man of wide outlook who desires opportunities for travel, sport, and games, and can find interest and enjoyment in aviation.

His duties will, as a matter of course, give him flying experience as a passenger, which is necessary for the proper study of the medical problems of aviation and for gaining first-hand knowledge of the conditions under which his comrades serve.

The establishment will consist partly of permanent and partly of short-service officers.

An officer will on first entry be granted a short-service commission for a period of three years on the active list (which may be extended to five years at the discretion of the Air Council if the officer so wishes on the recommendation of the Director of Medical Services) and of four years in the Reserve of Air Force Officers. Selections for permanent commissions will be made from officers holding short-service commissions, and those who are not selected will be transferred to the Reserve at the expiration of their period of service on the active list.

For those entrants who desire it the prospect of obtaining a permanent commission is approximately an even one. Experience has so far shown that the officers selected have included the great majority of those desirous of, and suitable for, retention in the Service; owing to the fact that the short-service commission with its gratuity after three or five years is in itself an attraction to many entrants who desire to enlarge their experience and outlook from the point of view of subsequently entering private practice, or who, on entry, have not made up their minds to the adoption of a permanent career in the Service and subsequently find that they would prefer to return to civil life.

For certain purposes medical officers may be allowed to count as service their time spent in resident appointments in civil hospitals under certain well-defined and generous conditions.

Officers who have been selected for permanent commissions may be permitted to attend for a period not exceeding nine months a post-graduate course

* Except for periods of service under Indian administration. For such periods officers receive pay and allowances at rates and subject to conditions authorised from time to time by the Government of India.

† These allowances are issued only when accommodation, fuel and light, rations, and personal attendance are not available in kind. Normally, provision in kind is available for junior officers. "Married" rates of allowances are payable only to married officers who have reached the age of 30 or the rank of Squadron Leader. A colonial allowance is granted in certain commands abroad. The rates and general scheme of allowances are liable to revision as circumstances may require.

in general medicine and surgery, tropical and preventive medicine, and other special subjects. Such permission may be granted at any time when the exigencies of the Service permit during the first 16 years of service, and when attending these courses officers will receive full pay and allowances.

New entrants into the Royal Air Force Medical Service will be commissioned as Flying Officers (Medical) and will be eligible for promotion to the rank of Flight Lieutenant (Medical) after two years' service. Officers selected for permanent commissions will normally be promoted to the rank of Squadron Leader after ten years' total service. Accelerated promotion may be granted in a limited number of cases to officers who show exceptional ability after the completion of eight years' service. Promotion within establishment to the rank of Wing Commander will be by selection at any period after 16 years' total service, and that of Group Captain by selection at any period after 22 years' service.

Certain posts in these ranks are reserved for officers fully employed in professional work, such as surgery, pathology, ophthalmology, &c., numbering at present six in all. The number of these posts will be limited only by the needs of the Service and by the necessity of observing a similar proportion between the number of reserved posts and the officers from whom they can be filled, as exists between the total number of higher ranks and the remainder of the medical service. Selections for these reserved posts will be made only from officers professionally qualified to hold them. Officers filling the reserved posts will be eligible for selection to the administrative appointments of their rank, and to the highest administrative appointments.

There will be no competitive examination on entry; candidates must be under 28 years of age, be British subjects, the sons of British subjects, and of pure European descent, be nominated by the dean of a recognised medical school or teaching hospital, and will be interviewed personally by the Director of Medical Services, Royal Air Force, before acceptance. Each candidate must produce:—

1. Birth certificate. 2. Medical registration certificate. 3. A declaration containing the following information: (*a*) Age and place of birth. (*b*) That he is a British subject, the son of British subjects, and of pure European descent. (*c*) That he is ready to engage for general service at home or abroad as required. (*d*) The qualifications he is possessed of, and what medical or other appointments he has held (if any). (*e*) That he is willing to fly as a passenger whenever called upon to do so.

Each candidate will be required, before acceptance, to pass a medical examination to ensure that he labours under no constitutional or mental disease or diseases or weakness, nor any imperfection or disability which may interfere with the efficient discharge of the duties of a medical officer in any climate, in peace or war.

On appointment entrants will undergo an initial course of eight weeks, during which they will be given instruction in the special medical aspects of aviation, the organisation and administration of the Royal Air Force, and the general and special duties to be performed by officers in the Medical Branch.

In order to avoid the necessity for further examinations the position of entrants in order of seniority in the Air Force List will be determined at the end of the initial course by a system of marking and reports on the actual work done during their instruction.

Uniform and Equipment.

Medical officers are required to provide themselves with the uniform, service dress and mess dress of their rank and with the distinguishing badges of the Royal Air Force Medical Branch. The provision of full dress is entirely optional at present. An allowance of £50 towards the cost of uniform is made on joining to candidates who have not had previous commissioned service in H.M. Forces.

Emoluments.

The emoluments of medical officers of the Royal Air Force are given in outline above. The standard rates of pay and retired pay were drawn up on the basis of the high cost of living in 1919, and 20 per cent. of each of the standard rates is detachable and subject to alteration either upwards or downwards as the cost of living rises or falls. Under this provision the current rates now in force represent a reduction of approximately 6 per cent. on the standard rates. The next revision will take effect from July 1st, 1930, and subsequent revisions will be made at intervals of three years.

RETIRED PAY.

The minimum period of service qualifying for retirement on retired pay is 20 years. Standard rates of retired pay are as follows:—

Air Officers.

Air Vice-Marshal ..	.. £790 to £1010 per annum.
Air Commodore ..	.. £650 „ £950 „ „

The maximum standard rates of retired pay and the compulsory retiring ages for the several ranks are:—

Rank.	Yearly rate of retired pay.	Compulsory retiring age.
	£	
Air Vice-Marshal ..	1010	60
Air Commodore ..	950	57
Group Captain.. ..	900	55
Wing Commander ..	600	51
Squadron Leader ..	500	48

Retired Pay of Officers below Air Rank.

Age on retirement.	Standard yearly rate of retired pay.	Years of service.	Addition for each extra year of service.*	Deduction for each deficient year of service.*
	£		£	£
40	300	17	15	15
41	337	17	15	15
42	375	18	15	15
43	412	18	15	15
44	450	19	15	15
45	487	19	15	15
46	525	20	15	15
47	562	20	15	15
48	600	21	15	15
49	637	21	15	15
50	675	22	15	15
51	697	22	22	15
52	720	23	22	15
53	742	23	22	15
54	765	24	22	15
55	790	24	22	15

* Limited to five years.

Gratuities.—A permanent officer allowed to retire before having qualified for retired pay may be granted a gratuity provided he has not less than ten years' commissioned service, namely:—

£1500 if he has 10 but less than 15 years' commissioned service.
£2500 „ 15 or more than 15 „ „ „

Short-service officers will be eligible on passing to the Reserve for gratuities on the following scale: £100 for each of the first two complete years of service, £150 for each of the third and fourth complete years, and £200 for the fifth complete year; that is:—

For three years' service on the active list ..	£350
For five „ „ „ „ ..	£700

These gratuities will not be payable to officers granted permanent commissions, but their service on a short-service commission will count towards retired pay.

COLONIAL MEDICAL SERVICE.

IN the self-governing Dominions (Canada, Australia, New Zealand, the Union of South Africa, the Irish Free State, and Newfoundland), and territories under their control, such as Papua and the Cook Islands and in the self-governing colony of Southern Rhodesia, medical appointments are made concerning which information can be obtained from the High Commissioners or Agents-General in London; application for appointments in North Borneo should be made to the British North Borneo Company, 17, St. Helen's-place, E.C., ; appointments in Sarawak are in the hands of H.H. the Rajah. Much valuable information will be found in the "Professional Handbook," Part II., issued by the Oversea Settlement Office, Caxton House, Tothill-street, London, S.W. 1, price 9*d.*

As a general rule, each Colony or Protectorate has its own public service distinct from that of every other; and it is usually only the higher officers who are transferred by the Secretary of State from one Colony to another. There are three exceptions to this rule: (*a*) The West African Medical Staff, which serves Nigeria, the Gold Coast, Sierra Leone, and the Gambia, is one service. (*b*) The East African Medical Service, which serves Kenya, Uganda, Zanzibar, Nyasaland, Somaliland, and the Tanganyika Territory is one service. (*c*) In practice the medical services of the Straits Settlements and the Malay States may be regarded as one, as the officers may be and frequently are transferred from the Colony to the States or vice versa; the two services are now called the Malayan Medical Service.

The Colonies, Protectorates, and Mandated Territories to which medical officers are appointed by the Secretary of State for the Colonies are (*a*) the West African—viz., Nigeria, the Gold Coast, Sierra Leone, and the Gambia, with the Mandated Territories of Togoland and the Cameroons; (*b*) the East African—viz., the Kenya Colony and Protectorate, Uganda, Nyasaland, Somaliland, and Zanzibar Protectorates, the Tanganyika Territory, and Northern Rhodesia; (*c*) the Eastern—viz., Ceylon, the Straits Settlements and Malay States, Hong-Kong, Mauritius, and Seychelles; (*d*) the West Indian—viz., Jamaica, Trinidad, the Windward Islands, the Leeward Islands, Barbados, and the Bahamas; (*e*) Fiji and the Western Pacific, Cyprus, Gibraltar, St. Helena, British Guiana, British Honduras, Bermuda, and the Falkland Islands; and (*f*) Palestine.

In Ceylon, Mauritius, Jamaica, Barbados, the Bahamas, and Bermuda vacancies are practically always filled locally by the appointment of qualified native candidates, or—in the case of some of the higher posts—by transfer from other Colonies. In the Bechuanaland Protectorate, Basutoland, and Swaziland appointments are usually filled locally. Appointments in Malta are all filled locally. In addition, certain medical appointments in the service of the Government of Iraq are filled with the concurrence, and normally upon the recommendation, of the Secretary of State. Vacancies occur most regularly and frequently in the West African Medical Staff, the East African Medical Service, and the Straits Settlements and Malay States.

All applicants for medical appointments in the gift of the Secretary of State for the Colonies should be *under 35 years of age, and must be doubly qualified*; preference will be given to those who have held hospital appointments as house physicians and house surgeons: testimonials to character and professional competence will be required, and every officer before being definitely appointed will be medically examined by one of the consulting physicians of the Colonial Office: Dr. P. H. Manson-Bahr, D.S.O., F.R.C.P., 9, Weymouth-street, Portland-place, W.1, and Dr. A. E. Horn, C.M.G., 14, Wimpole-street, W.1; Major-General J. J. Gerrard, C.B., C.M.G., the Royal Hospital, Kingsbridge, Dublin; Dr. Foster Coates, 22, College-gardens, Belfast; and Lieut.-Colonel Glen Liston, C.I.E., I.M.S., 33, Comely Bank, Edinburgh, and Dr. C. V. Le Fanu, *39, Rodney-street, Liverpool. Applications* for such appointments must be addressed to the Private Secretary (Appointments), Colonial Office, 2, Richmond-terrace, Whitehall, S.W.1.

Instruction in Tropical Medicine.—Every candidate selected for appointment will, unless the Secretary of State decides otherwise, be required to undergo a course of instruction at the London School of Hygiene and Tropical Medicine, Endsleigh-gardens, W.C.1, the Liverpool School of Tropical Medicine, Liverpool University, or at Edinburgh University. The cost of tuition will be borne by the Government, but candidates must make their own arrangements for board and lodging; an allowance of £25 a month will be paid to them monthly in arrear while they are under instruction. Payment of the allowance will be made subject to the candidate signing an agreement by which he is bound to refund it (1) if he declines to accept an appointment in any of the Colonies for which he may be selected; (2) if he fails to obtain a certificate or diploma; (3) if he leaves the Service within three years for any reason other than mental or physical infirmity not caused by his own misconduct.

EAST AFRICAN MEDICAL SERVICE.

The Medical staffs of the Kenya Colony and Protectorate, the Uganda, Nyasaland, Somaliland, and Zanzibar Protectorates, and the Tanganyika Territory form one service, the members of which are liable to be posted or transferred to any of the Dependencies as the exigencies of the service may require. The preferences of individual officers are, however, taken into consideration as far as possible.

Selected candidates are appointed as medical officers on probation in the first instance for two years, at the end of which period their appointments are made permanent if their service has been satisfactory. Medical officers (but not health officers) are permitted to take private practice at some stations on the understanding that they give precedence to their official duties. It must be understood that additions to their income from this source are not likely to be substantial, and that the privilege is liable to withdrawal at any time.

Officers are provided with quarters free of rent or the Government may provide temporary accommodation, or an allowance in lieu of quarters may be paid. The salary of a medical or sanitation officer is £600 per annum, rising by annual increments of £30 to £840, and thence by increments of £40 to £920, subject to an efficiency bar at £840. Senior medical officers and senior sanitation officers are paid on the scale £1000 by annual increments of £50 to £1100. Officers who possess the Diploma in Public Health on entering, or who acquire it while in the Service, receive two special increments in the scale.

Officers of the East African Medical Service are permitted to retire with gratuity, if they wish, instead of waiting to retire on pension as follows: (*a*) After nine years' service, of which at least six must have been spent in East Africa, £1000; (*b*) after 12 years' service, of which at least eight must have been spent in East Africa, £1250. If an officer elects to retire with gratuity he thereby forgoes all claim to pension.

The grades and salaries (apart from ordinary medical and sanitation officers) in the medical departments are as *follows*:—

Kenya.—Director of Medical and Sanitary Services, £1500; Deputy Director of Medical Service, £1200; Deputy Director of Sanitary Service, £1200; Deputy Director of Laboratory Service, £1200.

Uganda.—As Kenya.

Tanganyika Territory.—As Kenya.

Nyasaland.—Director of Medical and Sanitary Services, £1200; Medical Entomologist, £1000–£50–£1100.

Zanzibar.—Director of Medical and Sanitary Services, £1400; Deputy Director of Sanitary Service, £1200; Resident Surgical Officer, £1000–£50–£1100.

Somaliland.—Principal Medical Officer, £1000–£50–£1100.

There are also the following posts:— Resident Surgical Officers (Kenya and Uganda), £1200; Specialist Officer, Sleeping Sickness (Uganda), £1150; Medical Superintendent and Principal of Medical School, Mulago Hospital (Uganda), £1150; Sleeping Sickness Officer (Tanganyika Territory), £1000–£50–£1100; Senior Bacteriologists (Kenya and Uganda), £1000–£50–£1100.

Health officers are selected from the ranks of medical officers as occasion arises.

ASIA.

Straits Settlements and Federated Malay States.—European medical officers are appointed on the following scale of salaries: $500 per mensem, rising to $550 per mensem during three years' probation; then, if they are placed on the pensionable establishment, rising to $575 per mensem, and thence by annual increments of $25 per mensem to $800 per mensem, with a strict efficiency bar at $600 per mensem. Officers possessing the D.P.H. receive an additional allowance (non-pensionable) of $100 per mensem.

Above the concluding figure of $800 per mensem there are certain higher appointments, as follows: Principal Civil Medical Officer, Straits Settlements, and Principal Medical Officer, Federated Malay States, $1200 per mensem; Director, Institute for Medical Research, Federated Malay States, Chief Health Officer, Federated Malay States, and Principal Medical College, Straits Settlements, $1100 per mensem; 12 posts at $1050 per mensem; and 20 posts at $850 per mensem, rising annually by $30 to $1000 per mensem.

The following temporary allowances are at present paid to all officers recruited from Europe in the Government Services of the Straits Settlements and Federated Malay States: unmarried officers, 10 per cent. of salary; married officers, 20 per cent. of salary. Private practice by Government medical officers is not allowed, but consultation work with another practitioner is permitted. Information about general conditions in Malaya is obtainable from the Malayan Information Agency, 57, Charing Cross, S.W. 1.

Seychelles.—The chief medical officer receives Rs.7000 per annum. There are four assistant Government medical officers, two receiving Rs.6500, the others Rs.3000 per annum.

Hong-Kong.—The present establishment of the medical department is: director of medical and sanitary services, £1200–£50–£1450; deputy director, £1125–£25–£1200; senior medical officer, £1025–£25–£1100; three medical officers of health, £740–£30–£1040; health officer of the port, and second health officer of the port, £740–£30–£1040; five medical officers, £600–£30–£1020; bacteriologist, £800–£1100; assistant bacteriologist, £740–£30–£1040; radiologist, £740–£30–£1040; analyst, £625–£25–£900; assistant analyst, £400–£25–£700. A temporary allowance on a scale varying with the sterling exchange value of the dollar is at present payable. Salaries are converted locally at the rate of 2*s.* = $1. Free quarters are not provided, but in certain instances a rent allowance is paid by the Government.

AMERICA.

British Guiana.—There are the following posts in the medical service of the Colony: one surgeon-general, £1000–£1200 per annum, with consulting practice; one medical officer of health, £900; ophthalmologist, £700; one bacteriologist and pathologist, £700; 37 medical officers at £500–£25–£700. Most of the senior posts in institutions carry duty allowances (varying from £50 to £300 per annum) and quarters.

Trinidad and Tobago.—In Trinidad and Tobago there are about 40 appointments. Government medical officers receive salary at the rate of £400 per annum, rising by annual increments of £25 to £600. An officer appointed to a district receives, in addition to his salary, a travelling allowance varying from £100 per annum in a normal district to £150 per annum, and is allowed private practice, the value of which is estimated at from £50 to £800 per annum. Officers employed in institution work receive a duty allowance varying from £50 to £300. Medical officers having completed 10 years' resident service are pensionable at the age of 55.

Windward Islands (Grenada, St. Lucia, St. Vincent). There are over 25 appointments. The chief medical officer, Grenada, receives £750. The chief medical officer, St. Lucia, receives £600–£700 plus forage and subsistence allowances; the post is pensionable, but private practice is not allowed except as a consultant. Most of the remaining appointments are district appointments with the right to private practice attached; the salaries paid by Government are on the scale from £400–£500, except in St. Vincent, where the maximum is £450. The Governor has the power to transfer a medical officer from one island to another. Appointments are pensionable.

Leeward Islands (Antigua, St. Christopher and Nevis, Dominica, Montserrat, Virgin Islands).—The appointments are similar in number and character to those in the Windward Islands, and are pensionable. An officer when first sent out is not appointed to a particular island but to the service of the Leeward Islands, with a salary of £350, and is later appointed to a definite district at a salary varying from £312 to £400–£25–£450, and the Governor decides as to the district which is to be allotted to him, according to station. He is liable to be transferred at the Governor's discretion to any medical district in the Leeward Islands. The medical officers, except in St. Christopher and Nevis, receive fees for successful vaccinations, post-mortem examinations, evidence at courts of justice, certificates of lunacy, and, in the larger islands, for burial certificates. They are also, as a rule, allowed private practice. The chief medical officer, St. Christopher and Nevis, receives £700–£25–£750, but is not allowed private practice, except as a consultant.

British Honduras.—There are seven medical appointments (besides the post of principal medical officer at a salary of $2430 per annum with increments of $120 to $3150. Unless they already possess a diploma of public health, medical officers are liable to be required, before they join the colony, to undergo a course of instruction at a laboratory of public health or analogous institution. The value of the dollar is the same as that of the United States dollar.

OTHER OVERSEAS APPOINTMENTS.

Fiji.—The Chief Medical Officer receives £1000–£50–£1100, with free quarters, unfurnished; the Medical Superintendent, Colonial War Memorial Hospital, £800–£50–£1000, with £40 car allowance and free quarters; the Medical Superintendent, Leper Asylum, £750–£50–£950, with completely furnished quarters and one servant; the Medical Officer of Health, £750–£25–£900, no quarters provided. There are 14 District Medical Officers who receive £500–£25–£725, with partly furnished quarters or £50 house allowance (at the option of the Government) and duty allowance of £50 per annum in districts where no private practice exists. In certain districts house allowances or car allowances are granted. In others a medical officer is provided with a launch or boat. District Medical Officers are allowed private practice on the understanding that their official duties are not neglected. In five districts the Medical Officer is also District Commissioner and receives an additional allowance of from £175 *to* £275 and free partly-furnished quarters. In most districts there is private practice, the value of which has been estimated at from £100 to £600 a year.

Western Pacific High Commission.—The staff in the British Solomon Islands Protectorate consists of a Senior Medical Officer (£650–£750), two District Medical Officers (£550–£650), and one Travelling

Medical Officer (£550–£650). Partly-furnished quarters are provided and a local allowance of £50 per annum is paid to the Senior Medical Officer and the District Medical Officers. A local allowance of £50, consolidated travelling and subsistence allowance £200, and partly-furnished quarters are provided for the Travelling Medical Officer.

In the Gilbert and Ellice Islands Colony there is a Senior Medical Officer (£650–£750), with partly-furnished quarters, and one Medical Officer (£600–£25–£650), with partly-furnished quarters or house allowance. There is hardly any private practice in the British Solomon Islands Protectorate or the Gilbert and Ellice Islands Colony.

Cyprus.—There is a chief medical officer paid at the rate of £750, rising by annual increments of £25 to £850, and three district medical officers paid at the rate of £500 a year, rising by annual increments of £20 to £600 a year, all enjoying private practice (except the chief medical officer and one of the district medical officers, who are allowed consulting practice only). There is also a post of consulting surgeon, £400–£20–£600 a year, with consulting practice. There is also a medical officer of health on £600, rising by £20 increments to £750 without private practice, and a specialist in venereal diseases with a salary of £700 a year and consulting practice; these are the only medical appointments open to British candidates.

Gibraltar.—There is a surgeon of the Colonial Hospital receiving £730, and private practice. There are also two assistant surgeons with a salary of £600 for 3 years and thereafter £650–£25–£700 per annum, who are allowed private consulting practice only. Free quarters, unfurnished, are provided for all three officers.

St. Helena.—The colonial surgeon at present receives £550 per annum, fees estimated at about £27 a year, and £30 horse allowance. The assistant colonial surgeon at present receives £500 a year and £30 horse allowance. Private practice is allowed, and such practice, together with the duties of non-Government appointments, is divided between the colonial surgeon and the assistant colonial surgeon in a proportion approved by the Governor. The value of private practice and appointments is estimated at about £530 a year.

Falkland Islands.—There are two appointments. The colonial surgeon is paid at the rate of £800 per annum, with free furnished quarters, and £200 in lieu of private practice. The assistant colonial surgeon is paid at the rate of £500 per annum, with an allowance of £50 per annum in lieu of quarters, and is allowed private practice. The office of colonial surgeon is pensionable.

Palestine.[1]—The grades and salaries of higher appointments in the Department of Health are: Director, £P.1200, plus £P.200 expatriation allowance. Deputy Director, £P.900–50–£P.1100, plus £P.150 expatriation allowance. Assistant Director (Laboratories), Specialist Surgeon,[2] and five Senior Medical Officers, £P.750–25–950, plus £P.100 expatriation allowance. One Senior Medical Officer and Government Analyst, £P.550–25–750, plus £P.100 expatriation allowance. The remainder of the staff is recruited locally. A temporary and variable cost-of-living allowance is at present payable in addition to the salaries stated above.

Iraq.—The grades and salaries of the principal appointments in the Department of Health are: Inspector-General of Health, Rs.1800–100–2800 a month; Health Specialists, Directors of Hospitals and Institutes, Chief Medical Officers in Mosul and Kirkuk, Medical Officers of Health in Baghdad and Basra, Rs.1500–75–1800–100–2300 a month; Medical Officers, Rs.1200–75–1800 a month. Posts in the service of the Government of Iraq are not pensionable. Every officer (unless serving on a 3 years' contract) is required to contribute one-twelfth of his pay to a provident fund, to which the Government makes a contribution equal to one-sixth of his pay.

LEAVE AND PENSIONS.

Leave and Passages.—Leave of absence in East Africa. The normal tour of service is 20 to 30 months (less in Somaliland) after which leave is granted with full salary for 2½ to 3½ days, according to the districts in which the officer has served, for each month of service, plus the period of the voyage to England. If the officer is returning to East Africa for further service, he receives a further similar amount of leave, plus the period of the voyage to East Africa. Extensions of leave with full salary are given in case of sickness or in the case of officers attending approved courses of instruction. In addition to the above, local leave may be granted up to 14 days a year. Officers serving in Northern Rhodesia are allowed four (or two) days' leave in respect of each month of service. Free first-class passages are provided for the officer on first appointment and on leave, and in certain cases assistance towards family passages is given.

In the Malay Peninsula two months' leave of absence with full salary may be granted in respect of each year's service, and this leave may be accumulated up to a maximum of eight months. Additional leave on half-pay may be granted on special grounds. Officers are provided with free passages on first appointment for themselves and their families (i.e., wife and children up to five persons, inclusive of the officer). Under temporary regulations at present in force, free return passages on leave to all officers (and their wives and their children under the age of 10) irrespective of salary. Improvements in the leave conditions of officers serving in Malaya are under consideration.

In other Colonies outside Tropical Africa, subject to the necessities of the service, leave of absence on half salary may be granted after a period of three years' resident service without any special grounds. It may be given before the expiration of that period in case of serious indisposition, or of urgent private affairs. In the absence of special grounds, the leave must not exceed one-sixth of the officer's resident service; on special grounds it may exceed that period by six months. In addition to the above, vacation leave on full pay may be granted, if no inconvenience or expense is caused thereby, not exceeding three months[3] in any two years. British Guiana, Jamaica, and Trinidad officers are allowed to accumulate full-pay leave at the rate of six weeks for each year's service up to six months, exclusive of the period of the voyages to and fro, and no leave of absence may (except in very special circumstances) exceed six months in all unless the officer has served for five years or more without leave, in which case two months on half-pay may be taken in addition to six months' full-pay leave.

On first appointment an officer will, except in the case of a few Colonies possessing Representative Assemblies, be provided by the Crown Agents for the Colonies with free passages to the Colony for himself and his wife and children, if any, not exceeding four persons besides himself. The officer so appointed will be required to execute an agreement binding him to repay the cost of the passage or passages so obtained in the event of his leaving the Government service within three years. An officer taking leave out of the Colony has in most cases to provide his own passages.

Pensions.—East Africa.—Officers on the pensionable establishment may retire (or be retired by the Government) on attaining the age of 50 years; but they may be retained in the service, with their own consent, for such further period as the Government may recommend. Earlier retirement in the event of ill-health is also provided for. Pension is computed at one-four hundred and eightieth of pensionable emoluments—i.e., salary and value of free quarters[4] in respect of each month's pensionable service—at the time of retirement, subject to an average of emoluments for the last three years before retirement instead of the actual emoluments at the time of retirement being taken as the basis for calculation in certain circumstances.

---

[1] £P.1 = £1 sterling.

[2] A certain amount of private practice is allowed.

[3] Or, in the case of Fiji and the Western Pacific and the Falkland Islands 4½ months in any three years.

Other Colonies.—In most of the other Colonies an officer holding a pensionable appointment may be allowed in the case of ill-health to retire on a pension after ten full years' resident service; otherwise he must have attained the age of 55. For ten full years' resident service fifteen-sixtieths of the average annual salary of the retiring officer's fixed appointments for three years prior to retirement may be awarded, to which one-sixtieth may be added for each additional year's service; but no addition will be made in respect of any service beyond 35 years. For pension purposes absence on vacation leave counts as full service, and leave on half-pay as half service. In a few cases the retiring age is 60 and the pension after ten years' service is ten-sixtieths instead of fifteen. In the Straits Settlements and Malay States, an officer may, with the consent of Government, retire at age 50. Pensions are calculated on a basis of length of service in months instead of years.

WEST AFRICAN MEDICAL STAFF.

Applicants for appointment as medical officers or medical officers of health in the West African Medical Staff (the higher grades will usually be filled by promotion from the lower) must be British subjects of European parentage and between 23 and 35 years of age; preference is given to candidates who are over 25 years of age. Applicants must possess a complete double qualification, and must be on the Medical Register. Passages for wives and children are not provided by the Government, and houses for the wives of junior medical officers are rarely available. Officers are not usually allowed to take their wives and young children out with them until they have acquired experience of the local conditions and have obtained the sanction of the Governor. When an officer has obtained permission to be accompanied by his wife a grant of one-half the cost of his wife's passage to and from West Africa is made subject to certain conditions.

Candidates are allowed to express a preference for any particular Colony, and their wishes in this respect will be borne in mind and met as far as possible, but they are liable to be posted in the first instance, or transferred afterwards if necessary to any other West African Colony at the discretion of the Secretary of State. Candidates who wish to be posted to Nigeria will probably find it useful to be able to ride. Transfers from one Colony to another will be made as seldom as possible. Candidates should on no account apply for, or accept, a West African appointment in the expectation of ultimately being transferred.

Those transferred to pensionable Crown appointments elsewhere than in West Africa do not forfeit their claim to pension in respect of their West African service on final retirement, provided that they have been members of the staff for at least 12 months. Every officer selected for appointment is required to have himself revaccinated before proceeding to West Africa, unless one of the medical advisers of the Colonial Office certifies that this is unnecessary.

Leave of Absence.—European officers in West Africa may be granted vacation leave on full salary not exceeding in all one week's leave in the United Kingdom for every completed calendar month of total residential service in West Africa, plus the time necessarily taken on the journey to the United Kingdom, and, if the officer is returning to West Africa for further service, the time necessarily taken on the journey from the United Kingdom to the Colony. Vacation leave may be granted without any special grounds after 18 consecutive calendar months of residential service in West Africa. An officer will not be required to serve a tour of more than 24 consecutive calendar months' residential service except in special circumstances; and the Governor may grant vacation leave to any officer at any time after he has completed 12 consecutive calendar months' residential service within the above limits, the actual length of each officer's tour will be at the discretion of the Governor. Vacation leave on full salary may also be granted to an officer if he is invalided from West Africa after less than 12 consecutive calendar months' residential service, and sick leave on full salary may be granted for any period not exceeding six calendar months.

Appointments and Salaries.—Medical officers for the West African Colonies and Protectorates—namely, the Gambia, Sierra Leone, the Gold Coast (including Ashanti and the Northern Territories), and Nigeria (Southern and Northern Provinces)—are selected by the Secretary of State for the Colonies, and are on one list for employment and promotion. The grades and emoluments of the Staff are at present as follows:—

The Director of the Medical and Sanitary Service, Nigeria, receives a salary of £1800 a year, with a duty allowance at the rate of £300 a year. The Director of Medical and Sanitary Service in the Gold Coast receives a salary of £1600 a year, with a duty allowance at the rate of £320 a year. The Director of Medical and Sanitary Service in Sierra Leone receives a salary of £1400 a year, with a duty allowance at the rate of £280 a year. The Deputy Director of Medical and Sanitary Service, Nigeria, and the Deputy Director of Sanitary Service, Nigeria, receive salaries of £1500 a year, with duty allowances at the rate of £300 a year. The Deputy Director of Medical and Sanitary Service, Gold Coast, and the Assistant Director of Medical and Sanitary Services, Nigeria, receive salaries of £1400 a year, with duty allowances at the rate of £280 a year. Assistant Directors Medical Service: There are seven appointments on this grade, five in Nigeria, two in the Gold Coast. The salary is at the rate of £1300 a year, with duty allowance at the rate of £260 a year. The Assistant Director of Sanitary Service, Nigeria, the Deputy Director of Sanitary Service in the Gold Coast and the Deputy Director of Sanitary Service in Sierra Leone receive salary at the rate of £1300 a year, with duty allowance at the rate of £260 a year. Specialists: The number of these appointments is not fixed, officers of outstanding professional merit being eligible for appointment. The salary is at the rate of £1300 a year, with duty allowance at the rate of £260 a year. After five years' approved service as such, the specialist officer is eligible to receive a salary at the rate of £1400 a year, with duty allowance at the rate of £280 a year. There are at present five officers appointed specialists in Nigeria, three in the Gold Coast, and one in Sierra Leone. Senior Medical Officer: There are twenty appointments of this grade, with salary at the rate of £1000 a year, rising by annual increments of £50 to £1150 a year, and seniority allowance at the rate of £100 a year. The Senior Medical Officer, Gambia, is allowed "staff pay" of £150 a year, in addition to duty allowance, but he is debarred from private practice. Senior Sanitary Officer: There are nine appointments of this grade, with salary at the rate of £1050 a year, rising by annual increments of £50 to £1200 a year, and a duty allowance at the rate of £210 a year. Possession of the Diploma in Public Health is usually required for appointment to this grade. Special facilities are granted to study for the diploma during leave. Medical Officers of Health: There are at present 24 appointments of this grade. The salary scale is the same as that of Medical Officers, except that Medical Officers of Health are granted an initial salary at the rate of £800 a year, together with seniority allowance at the rate of £72 a year and staff pay at the rate of £150 a year, half of which is payable during leave. After three years' service on the maximum of the scale, viz., £960 a year, and on undergoing an approved course of study, Medical Officers of Health are eligible, if unpromoted, subject to the recommendation of the Governor, to be placed on the scale £1000 a year rising by annual increments of £50 to £1150 a year, together with seniority allowance at the rate of £100 a year and staff pay as before. The holders of these appointments are not allowed private practice. Candidates selected for service as Medical Officers of Health must obtain the Diploma in Tropical Medicine and Hygiene of Cambridge, London, or Liverpool as a condition of appointment, or must be in possession of the Diploma in Public

---

[4] The value of free quarters for pension purposes is taken as 15 per cent. of the minimum salary of the grade in which an officer is serving at the time of retirement, subject to a maximum of £150.

Health. They are appointed subject to the condition that, if after a period of service in West Africa they are considered unsuitable to serve in that capacity, they may be called upon to transfer to the medical side. In such cases the officers are given the rate of salary which they would have reached if they had been appointed to be Medical Officers instead of Medical Officers of Health in the first instance. Medical Officer: The salary attached to this grade is at the rate of £660 a year, rising by annual increments of £30 to £720 a year. Then, if confirmed in the appointment, £720 a year, rising by annual increments of £40 to £960, with seniority allowance at the rate of £73 a year. Before passing £800, medical officers are required to take a special course of study for three months. If they obtain satisfactory certificates at the end of the course they draw their further increments up to £960 a year.

A medical officer who has served for three years on the maximum salary of this scale (£960) without obtaining promotion is eligible, if recommended by the Governor, to be placed on the scale £1000–£50–£1150, with £100 seniority allowance (as for Senior Medical Officers).

Special Appointments.—The Director of the Medical Research Institute, Lagos, and the Director of the Medical Research Institute, Accra, receive a salary of £1300 a year, with a duty allowance of £200 a year, rising after five years' approved service to a salary at the rate of £1400 a year and duty allowance at the rate of £280 a year. There are a number of appointments for pathologists and bacteriologists in Nigeria, the Gold Coast, and Sierra Leone. The salary and other conditions attached to these posts are similar to those of Medical Officers of Health. Duty allowances, seniority allowance, and staff pay are not pensionable emoluments.

Increments.—Increments to salaries are payable only when the service of an officer during the period of employment qualifying for increment is approved.

Payment of Salaries.—Information as to the payment of officers' salaries or of monthly remittances to persons in England may be obtained from the Crown Agents for the Colonies, 4, Millbank, S.W. 1. All allowances are paid locally.

All officers of the staff, except directors, deputy directors, assistant directors, senior sanitary officers, medical officers of health, research officers, and a few other officers holding special appointments, are at present allowed to take private practice, provided that it does not interfere with the faithful and efficient performance of their official duties, but it is within the power of the Governor to withdraw or suspend the privilege in such places and for such periods as he may consider desirable. Private practice does not exist at many stations, and no guarantee can be given that an officer will be posted to a station in which he will be able to practise privately. As a general rule, and subject to the exigencies of the service, stations where there is private practice are allocated to senior members of the Staff.

Pensions and Gratuities.—Pensions and gratuities on retirement are granted in accordance with the law and regulations of each individual Colony.

African Medical Officers.—In addition to the membership of the West African Medical Staff, which is limited to British subjects of European parentage, there are a number of Government appointments for African medical officers in the West African Colonies. These appointments carry a salary on the scale £500–20–£600, and there is a higher scale, £600–30–£720. In addition, in Nigeria and on the Gold Coast, arrangements have been made for the employment of a few young African medical men temporarily on the hospital staffs, with a view to appointment to the Government service later, if suitable. In such cases a salary of £400 a year is paid.

SUDAN MEDICAL SERVICE.

This Service is responsible for carrying out civil, medical, and public health duties in the Sudan.

The staff consists of: (*a*) A Director, pay £1500–£2000. (*b*) A Senior Physician and a Senior Surgeon to the Khartoum and Omdurman Civil Hospitals, each with a pay of £1200–£1750. (*c*) An Assistant Director. (*d*) Medical Officer of Health, Khartoum Province, at a special rate of pay. (*e*) 31 British "Senior Medical Inspectors" and "Medical Inspectors" whose pay commences at £720 and rises, subject to the recommendation of the Director, by five biennial increases to £1080, and after 13 years' service to £1200. The Senior Medical Inspectors are eligible, by selection, for the four senior posts. All Medical Inspectors are appointed, in the first place, on probation for two years, and if at the end of that time they are accepted for permanent service under the Sudan Government, the first increase of pay is subject to their passing an examination in Arabic.

In addition to the above there are (*f*) a number of Medical Officers trained at one of the Syrian Medical Schools, besides (*g*) Sudanese Medical Officers trained at the School of Medicine at Khartoum. There are several native (*h*) Assistant Medical Officers, who have been given a purely practical training in one of the larger hospitals in the Sudan.

Amongst the attractions of the Service are: The great variety of the work met with among many different races of the Sudan; *leave* of 90 days, which is granted every year after the first 18 months of service; *study-leave*, which may be given for some definite purpose, whilst two years towards pensionable service may be granted to those who have special qualifications and experience. The pension for Medical Inspectors who retire after 20 years' service is not less than £E.500 a year. If, however, he serves for a longer period, or is appointed to one of the higher posts, he will receive a larger pension. Private practice is allowed, but is limited to a few of the larger towns, and may be carried on so long as it does not interfere, in any way, with official duties. These duties include acting as consultant to the principal hospitals and the supervision of medical and public health work, the inspection of schools, the examination of candidates for Government service and pension, and the training of Assistant Medical Officers and native Sanitary Overseers. The Khartoum Medical School is staffed mainly by members of the Medical Service, who receive additional remuneration for their work as teachers. A Registrar of the Medical School is also selected from the Service, who receives £250 a year extra pay.

The country is developing rapidly, and the Medical Department is being increased to meet its growing requirements. Vacancies are always advertised in THE LANCET as they occur.

Candidates must be single and should be under 30 years of age, and they must have held a resident post, preferably that of house surgeon, in a large general hospital. As a rule they are required to take out a course in Tropical Medicine before they leave England for the Sudan. The fees for this course are paid by the Sudan Government, and in addition an allowance £.E.25 per month is made, under certain conditions, to each selected candidate who attends it.

Inquiries for further information should be made to Dr. Hodson, 24, Welbeck-street, London, W.1, or to the Deans of the Principal Medical Schools.

WOMEN'S MEDICAL SERVICE FOR INDIA.

AMONG careers open to medical women abroad the Women's Medical Service for India deserves honourable mention. This service is open to fully qualified medical women of British or Indian nationality, and with the present amount of Government subsidy the number of medical officers is limited to 42. Medical women proceeding to India to join the Women's Medical Service receive a sufficient sum for a first-class passage to India. On landing they are posted to one of the larger women's hospitals to gain Indian experience and to learn the language. During this period (from six months to two years) private practice is not allowed. For a further period they are appointed to act temporarily for medical women on furlough, during which time private practice is allowed. They are then definitely appointed to the charge of hospitals. Private practice is always allowed after the first two years, provided it does not interfere with official duties. The only exception is in administrative or educational posts, when an allowance in lieu of practice is given. The amount obtained from practice varies according to the station, but in most cases it forms a fair addition to the salary, varying from £150 to £1000 a year.

Excellent opportunities for surgery—especially gynæcological—are found in the Women's Medical Service. To those who are not keen surgeons opportunities are likely to open in the future in connexion with maternity and child welfare; medical women with administrative ability are also needed for the inspection of women's hospitals and other medical institutions.

Rates of pay are as follows:—

Years of service.	Overseas allowance per mensem.	Salary per mensem.	English equivalent* per annum.
1 to 3	Rs.100	Rs.450	£440
4 to 6	,,	Rs.500	£480
7 to 9	,,	Rs.550	£520
10 to 12	,,	Rs.600	£560
13 to 15	Rs.150	Rs.650	£600
16 to 18	,,	Rs.700	£640
19 to 21	,,	Rs.750	£680
22 to 24	,,	Rs.800	£720
over 24	,,	Rs.850	£760

* At rupee value 1*s.* 4*d.*

Furnished quarters are provided, representing an additional Rs.150 per mensem.

The cost of living in India is much higher than formerly, but it should be possible for a medical woman (with house provided) to meet actual household expenses for about Rs.200 per mensem, leaving the remainder of her salary for dress and personal expenses. To this must be added the necessary saving to meet additional expense for furlough and leave spent in the hills.

One month's privilege leave on full pay is granted each year. Furlough on half-pay at the rate of two months for every year of service is granted after every three years. Study-leave on two-thirds pay is granted to the extent of 12 months in the total service. There is a provident fund to which members of the service contribute 10 per cent. of their pay. The service contributes another 10 per cent., which accumulates at interest and is repaid on retirement.

Admission to the service is made by selection. Candidates in the United Kingdom should apply to the Hon. Secretary, United Kingdom Branch of the Countess of Dufferin's Fund, care of Lt.-Col. Sir Leonard Rogers, India Office, Whitehall, London.

GUILD OF ST. LUKE.

THE Guild of St. Luke was founded over 60 years ago by a few medical students, chiefly to meet their own religious needs. It now makes a wider appeal, and its membership is open to all students and practitioners of medicine, both men and women, who are members of the Church of England, the clergy of which are eligible as Clerical Associates. The Chapter meets in every month of each term, and a festival service is held yearly at St. Luke's tide, usually at St. Paul's or Westminster Abbey. This year the service will be at the Abbey. Besides the parent Guild, there are a Women's Ward and a Hospital Student's Branch in London. There are also a Midland Counties Ward and a Cambridge Ward. Particulars of the objects and activities of the Guild and forms of application for membership can be obtained from the Secretary of the Guild of St. Luke, King's College, Strand, W.C.2.

SPECIAL DIPLOMAS.

DIPLOMA IN TROPICAL MEDICINE.

ALTHOUGH a qualification in tropical medicine has not been made registrable by statute, a diploma is regarded as indispensable for appointments in the Colonial Medical Service and similar positions abroad. Systematic instruction for these diplomas is given at the Incorporated Liverpool School of Tropical Medicine (founded in 1898) and at the London School of Hygiene and Tropical Medicine, Keppel-street, Gower-street, London, W.C.; while the Universities of Cambridge, London, Edinburgh, and the English Conjoint Board grant the diploma.

London School of Hygiene and Tropical Medicine.—The courses of study in all branches of the work of the School will commence in October in the new premises in Keppel-street (Gower-street), the gift of the Rockefeller Foundation, which has excellent laboratories and research rooms, a fine lecture theatre and classrooms, library, and museum.

The courses of study in Tropical Medicine and Hygiene which have hitherto been given at Endsleigh Gardens will be given in the new building. There are two courses in the year, each lasting 20 weeks, inclusive of examinations. The dates for the commencement of the next courses are Sept. 30th, 1929, and Feb. 3rd, 1930. The course covers the work required for the D.T.M. & H. (England), and part of that required for the M.D. in Tropical Medicine of the University of London.

The first course of study for the Diploma in Public Health will commence on Sept. 30th, and will extend over a period of 12 calendar months. It is arranged in compliance with the requirements of the General Medical Council, and students taking the course will be able, should they so desire, to proceed to the new academic Diploma in Public Health of London University. The curriculum has been planned on very practical lines, and includes, in addition to work with Medical Officers of Health in two selected areas, a large number of visits to places of public health interest. A series of 5 o'clock lectures will be given by eminent authorities on special subjects, and these lectures will be open to members of the medical profession as well as to students of the School. The London County Council, the City of London, and various other bodies have placed their resources at the disposal of the School for teaching purposes.

The special course of study for the Diploma in Bacteriology covers a period of one academic year, beginning in October, and special three-monthly courses are given in Epidemiology and Vital Statistics.

University of Liverpool.—The University grants a Diploma in Tropical Medicine. At the end of each full course an examination is held by the University for its Diploma of Tropical Medicine (D.T.M.), which is open only to those who have been through the course of instruction of the school. The subjects of examination are (*a*) Parasitology and Tropical Pathology. (*b*) Entomology. (*c*) Tropical Medicine, including Ætiology, Symptoms, Diagnosis and Treatment of Tropical Diseases. The advanced course consists entirely of Practical and Clinical Laboratory Work, given at the laboratory at the University. Applications should be made to the Dean of the Medical Faculty, University of Liverpool.

The University also grants a diploma in Tropical Hygiene (D.T.H.). The subjects of examination are (*a*) Tropical Hygiene (including Sanitary Engineering, Vital Statistics and Epidemiology and Applied Parasitology and Entomology). (*b*) Practical Sanitation. (*c*) Bacteriology. (*d*) Chemistry (including Meteorology and Climatology). Two University Fellowships of £100 a year each are open to students of the school, amongst others. Accommodation for research work is to be had at the University Laboratory. The Mary Kingsley Medal is awarded by the school for distinguished work in connexion with Tropical Medicine.

University of Cambridge.—The examination for the Diploma in Tropical Medicine and Hygiene is divided into two parts. Part I. is held in Cambridge in April and Part II. in July in London. Candidates for Part I. are examined under the same regulations and in the same subjects as candidates for the Diploma in Public Health, but any qualification in medicine or surgery recognised by the proper authority of any country outside the British Dominions may be recognised. The subjects for Part II. are Medicine, Surgery, and Hygiene in their relation to Tropical Disease.

The examination will be partly in writing, partly oral, and partly practical or clinical (the clinical part will be conducted at a hospital for tropical diseases, at which cases will be submitted for diagnosis and comment). Every candidate who passes the examination to the satisfaction of the examiners will receive from the University a diploma (D.T.M. & H.) testifying to his knowledge and skill in tropical medicine and hygiene.

Further information respecting the courses of study and examinations may be obtained from Mr. J. E. Purvis, Public Health Chemical Laboratory, Cambridge.

University of Edinburgh.—Candidates for the Diploma in Tropical Medicine and Hygiene must be graduates in medicine and surgery of the University of Edinburgh or hold corresponding registrable degrees or qualifications of some other licensing body. The course of instruction, comprising a primary and a second course, is given during the autumn and spring terms, October to March, and includes Tropical Hygiene, Bacteriology, Entomology and Parasitology, Diseases of Tropical Climates (systematic and clinical), Tuberculosis, and Venereal Diseases. The primary course alone is also given during the summer term, April to June. Provision is made in the University for instruction in all subjects. The examinations are written, oral, and practical, and are held at the end of the courses. Candidates are required on the first occasion of presenting themselves for examination to appear for all the subjects. Candidates who fail to pass the entire examination within a period of 12 months after first appearance are required to reappear for all the subjects. The University is included in the list of Institutions whose courses of instruction in Tropical Medicine may be taken by officers on appointment to the Colonial Medical Services or during study-leave. Full particulars can be obtained from the Dean of the Faculty of Medicine.

Conjoint Board R.C.P. Lond., R.C.S. Eng.—The diploma of D.T.M. & H. Eng. is awarded on the results of an examination held twice yearly, in March and July. Candidates must possess a registrable qualification, and produce evidence of having attended (1) practical instruction in pathology, protozoology, helminthology, entomology, bacteriology, and hygiene in relation to tropical medicine in a recognised institution during not less than five months; (2) clinical practice of a recognised hospital for the same period. Conditions of study may be modified in the case of candidates of special experience. Further particulars from the Secretary, Examination Hall, Queen-square, London, W.C.1.

DIPLOMA IN PSYCHOLOGICAL MEDICINE.

The Universities of Cambridge, London, Durham, Leeds, Manchester, Edinburgh, Dublin, National University of Ireland, and the Conjoint Board of the R.C.P. Lond. and R.C.S.Eng. now grant diplomas in psychological medicine under conditions that are fairly comparable in the standard of the tests and in the duration of the courses; the details on these points can be obtained from the various examination bodies.

In London, courses of instruction for the Diploma in Psychological Medicine are given annually at the Maudsley Hospital, Denmark Hill, which has recently been definitely recognised as a school of the University of London. The course consists of two parts, commencing in January, and is adapted for the diploma of the Conjoint Board, the University of London, or the University of Cambridge. The parts may be taken separately; also during the year there are other short courses, lectures and demonstrations in psychological medicine.

Maudsley Hospital.—Appointments as clinical assistants are obtainable at the Maudsley Hospital. The holding of such appointments for varying periods satisfies the requirements of the different examining bodies in respect of practical study of mental disorders. The appointments and other facilities for clinical experience are open to qualified medical practitioners apart from the courses of instruction. Inquiries as to lectures should be addressed to the Director of the Central Pathological Laboratory, Maudsley Hospital, Denmark Hill, S.E.; and as to clinical facilities, to the Medical Superintendent at the same address.

Bethlem Royal Hospital.—A course of lectures and practical instruction for the Diploma in Psychological Medicine, granted by the various universities and the Conjoint Board, is held at Bethlem Royal Hospital, London, S.E., twice annually, during the spring and autumn. The fee for the full course is 15 guineas. Part A or Part B, however, may be taken separately at a fee of 10 guineas per part. In addition to the above, clinical instruction in Psychological Medicine is given at Bethlem Royal Hospital every morning (except Wednesdays) at 11 A.M. The fee for students is 3 guineas for a period of three months' attendance and for post-graduates a fee of 5 guineas for a like period. A reduction is made to those who attend the Diploma Course. House physicians are appointed at Bethlem Royal Hospital for a term of six months, which may be extended. These appointments are made on May 1st and Nov. 1st in each year and the vacancies are advertised in the medical papers. Apartments, complete board, attendance, and laundry are provided and also a salary at the rate of £100 per annum. Clinical assistants are often appointed from time to time for periods of three months or longer. These are non-salaried and non-resident posts, but partial board is provided. The Physician-Superintendent, Bethlem Royal Hospital, London, S.E., will supply further particulars.

University of Edinburgh.—Candidates for the Diploma in Psychiatry must be graduates in medicine and surgery of the University of Edinburgh or hold corresponding registrable degrees or qualifications of some other licensing body. Candidates are required subsequent to the date of graduation or obtaining a registrable qualification to have held (*a*) a resident appointment for one year in a hospital for mental disorders approved by the Faculty of Medicine, or alternatively (*b*) a six months' appointment as defined in (*a*) and six months' practical study of nervous diseases in a special or general hospital approved by the Faculty of Medicine. There are two examinations for the Diploma. Part I. comprises 1. Anatomy of the Nervous System. 2. Physiology of the Nervous System. 3. Psychology and Experimental Psychology. Part II. comprises: 1. Neuropathology. 2. Clinical Psychiatry. 3. Clinical Neurology. 4. An additional subject selected by the candidate from a prescribed list. The examinations are held twice yearly in March and July. Candidates who have held an asylum appointment for a period of five years or more may be exempted from the course of study in one or more subjects of the curriculum. Full particulars can be obtained from the Dean of the Faculty of Medicine.

Dublin University.—A post-graduate diploma in Psychological Medicine is conferred upon registered medical practitioners who have held a resident medical appointment at a recognised institution for the treatment of Mental Diseases for 12 months, or who have held such an appointment for six months and have attended clinical instruction at an approved institution for six months. Candidates must also attend special courses of instruction and pass a special examination. Details can be obtained from the Registrar of the School of Physic, Trinity College, Dublin.

The National University of Ireland confers a diploma in Mental Diseases ; application should be made to the Registrars of the Constituent Colleges, University College, Dublin University College, Cork, and University College, Galway, for all information.

DIPLOMA IN OPHTHALMIC MEDICINE.

Special diplomas in ophthalmic medicine and surgery are issued by two examining bodies.

University of Oxford.—The diploma in ophthalmology (D.O.) is granted to registered medical practitioners after passing an examination, held annually in March, which is open to candidates who have pursued at Oxford a course of study in ophthalmology over a period of at least two months and who have attended a 12 months' recognised hospital course. Further information regarding these requirements may be obtained from the Dean of the School of Medicine.

Conjoint Board R.C.P. Lond., R.C.S. Eng.—The Conjoint Board grants the D.O.M.S. after an examination held in two parts, twice yearly in February and July. Part I. comprises anatomy and embryology of the visual apparatus, physiology of vision, and elementary optics. Part II. comprises optical defects, ophthalmic medicine and surgery, and pathology with special reference to ophthalmology. The examination in each case is written, oral, and practical or clinical. Candidates may only enter for Part II. on completion of a year of special study of ophthalmology after obtaining a registrable diploma or a Degree in Medicine and Surgery of a University recognised by the Board.

DIPLOMA IN MEDICAL RADIOLOGY AND ELECTROLOGY.

University of Cambridge.—The D.M.R.E. is open only to those who have held for at least one year a medical qualification approved by the Committee. The new regulations, which came into operation in October, 1928, in some respects materially alter the scope of the Diploma. The course now occupies nine months, beginning in October. The first three months, which can be spent either in Cambridge or in London, are occupied with lectures and practical work in Physics in preparation for the examination for Part I. in January, and an introductory course in Radiology and Electrology. The second three months must be spent in London. The course includes lectures and clinical instruction in Radiology and Electrology, with clinical practice in the radiological department of a hospital approved for that purpose by the Committee. The examination for Part II. is held in April. During the final three months a candidate must hold a clinical clerkship or similar appointment in a radiological department approved by the Committee, and must then present a thesis in the form of a critical report with notes upon six cases either in Radiology or in Electrology or in both these subjects, illustrating various methods of diagnosis or treatment. A number of large provincial hospitals have been approved by the Committee to take clinical assistants for this part of the course.

Further particulars as to courses and examinations may be obtained from G. Stead, M.A., Cavendish Laboratory, Cambridge, Secretary for the Diploma, or from Dr. A. E. Barclay, Department of Radiology, Medical School, Cambridge, or from Dr. Stanley Melville, British Institute of Radiology, 32, Welbeck-street, London, W. 1.

University of Liverpool.—Candidates before admission to the examination for this diploma must possess a registrable qualification, approved by the University in medicine and surgery, and must have attended courses of instruction in (*a*) physics (two terms), (*b*) (*i*) radiology, and (*ii*) electrology during six months in the X ray and electrotherapeutic departments of a hospital or hospitals. An examination is held in March each year, the subjects being (*a*) physics, (*b*) radiology and electrology. Examination in either part may be taken separately. Fees: tuition, £24 5s.; examination and diploma, £6 5s. These courses commence during the first week in October. Application should be made to the Dean, Faculty of Medicine, the University of Liverpool.

University of Edinburgh.—Candidates for the Diploma in Radiology (D.R. Univ. Edin.) must be graduates in medicine and surgery of the University of Edinburgh or hold corresponding registrable degrees or qualification from some other licensing body. Candidates are not admitted to the examination for the Diploma until after the lapse of not less than one year from obtaining a registrable qualification, which qualification must be registered before admission to the Examination. The course of study begins in October and extends over a period of not less than three terms. The Examination, which is written, oral, and practical, is in two parts: (*a*) Physics, and (*b*) Radiology. The Examination is held twice yearly —viz., July and October.

Radiology can be taken as the special subject in the examination for Membership of the Royal College of Physicians of Edinburgh, which means that an Honours standard has to be attained. Full particulars may be obtained from the Dean of the Faculty of Medicine.

DIPLOMA IN LARYNGOLOGY AND OTOLOGY.

The Conjoint Board R.C.P. Lond., R.C.S. Eng., grants the D.L.O. after an examination held in two parts, twice yearly, in June and December. Part I. comprises anatomy, embryology, and physiology of the ear, nose, pharynx, larynx, trachea and bronchi, and œsophagus. Part II. comprises the medicine, surgery, and pathology of the ear, nose, pharynx, larynx, trachea and bronchi, and œsophagus, and the recognition and use of special instruments and appliances. The examination in each case is written, oral, and practical or clinical. Candidates may only enter for Part II. on completion of one year of special study of the diseases of the ear, nose, pharynx, and larynx, after obtaining a registrable qualification, or a degree in medicine and surgery of a University recognised by the Board. The fee for admission to each part is 6 guineas.

DIPLOMA IN TUBERCULOUS DISEASES.

A Diploma in Tuberculous Diseases is given by the University of Wales. The regulations governing the award of the diploma prescribe that every candidate must have obtained a registrable qualification in Medicine, Surgery, and Midwifery for at least two years before he can be admitted to the examination. He must have held, for not less than 12 months, a resident medical or surgical appointment on the staff of a Tuberculosis Hospital or Sanatorium, or at an Orthopædic Institution providing not less than one hundred beds for cases of surgical tuberculosis. A candidate whose resident appointment has been held at a Hospital, Sanatorium, or Institution receiving surgical cases of tuberculosis only, must produce a certificate of having attended a course of instruction in pulmonary tuberculosis extending over one term in the Welsh National School of Medicine, or an equivalent course of instruction extending over at least the same period in an institution approved by the University for this purpose. A candidate whose resident appointment has been held at a Hospital, Sanatorium, or Institution for medical cases of tuberculosis only, must produce a certificate of having attended a course of instruction in non-pulmonary tuberculosis extending over one term in the Welsh National School of Medicine, or an equivalent course of instruction extending over at least the same period in an institution approved by the University for this purpose. Every candidate must have pursued a course of instruction in the epidemiology, pathology, and bacteriology of tuberculosis extending over one term in the Welsh National School of Medicine, or an equivalent course of instruction extending over at least the same period in an institution approved by the University for this purpose. The examination, which is held annually in the first week of June, is divided into two parts, and every candidate is required to satisfy the examiners in both parts at the same examination. Notice of candidature, together with the entrance fee of £10 10s., and the necessary certificates, must be forwarded to the Registrar of the University, University Registry, Cathays Park, Cardiff, not later than May 1st.

The Cecil Prosser Research Scholarship, of the value of £250 for one year, is awarded triennially for research in Tuberculosis.

DIPLOMA IN PUBLIC HEALTH.

THE following epitomises the instruction given at various universities and centres of medical education to medical men desiring to obtain diplomas in sanitary science, public health, hygiene or State medicine, as this discipline is variously called. Resolutions, designed with a view of ensuring "the possession of a distinctively high proficiency, scientific and practical, in all the branches of study which concern the public health," have been adopted at various times by the General Medical Council. The diploma is registrable by the Council, whose rules on the curriculum become binding on the educational bodies concerned. The new regulations, which came into force in 1924, extend the period of study and postpone the granting of a diploma until at least two years from qualification.

Conjoint Board of the R.C.P. Lond. and R.C.S. Eng. New regulations came into force on Jan. 1st, 1924, which apply to all candidates who have not commenced recognised study of Public Health in accordance with the above regulations before that date. They are as follows: The Examination consists of two Parts. Part I. will be held in the months of January, June, and October, and Part II. in the months of January, June, and October in each year. Candidates may enter for Parts I. and II. separately or at the same time, but they must pass Part I. before proceeding to Part II. The Examination in each part will be written, oral, and practical. Part II. will include a practical examination in Infectious Diseases, Food Inspection, and Inspection of selected Premises. Candidates who fail to satisfy the Examiners in either part may present themselves again at the next Examination on payment of the same fees. Candidates intending to present themselves for either part of the Examination must give 14 days' notice in writing to the Secretary, at the Examination Hall, Queen-square, London, W.C. 1.

Candidates will be admissible to Examination in Part I. on producing evidence:—

1. Of being in possession of a registrable qualification in Medicine, Surgery, and Midwifery.

2. Of having attended during a period of not less than five months at an Institution recognised by the Examining Board in England, practical instruction in (*a*) Bacteriology and Parasitology (including Medical Entomology) especially in their relation to diseases of man and to those diseases of the lower animals which are transmissible to man, during 180 hours, of which not less than 150 hours have been occupied in practical laboratory work. (*b*) Chemistry and Physics in relation to public health, during 90 hours, of which not less than 70 hours have been occupied in practical laboratory work. (*c*) Meteorology and Climatology in relation to public health, during not less than 10 hours.

Candidates will be admitted to Part II. of the Examination on producing evidence:—

1. Of having been in possession of a registrable qualification in Medicine, Surgery, and Midwifery during not less than two years, of being registered by the General Medical Council, and of having completed the curriculum for the Diploma extending over a period of 12 calendar months subsequent to the attainment of a registrable qualification.

2. Of having attended, after obtaining the registrable Qualification, instruction during not less than 80 hours at an Institution recognised by the Examining Board in England in the following subjects:—(*a*) The Principles of Public Health and Sanitation for not less than 30 hours; (*b*) Epidemiology and Vital Statistics for not less than 20 hours; (*c*) Sanitary Law and Administration (including Public Medical Services) during not less than 20 hours; (*d*) Sanitary Construction and Planning during not less than 10 hours.

3. Of having attended for three months the clinical practice of a hospital for infectious diseases recognised by the Examining Board in England and of having therein received instruction in the methods of administration. The certificate must state that the candidate has attended on one or more days in each week of the three months, that each attendance was of two hours' duration, with a total attendance of 60 hours.

4. Of having been engaged during a period of not less than six months in acquiring a practical knowledge of the duties, routine and special, of public health administration under the supervision of a Medical Officer of Health, and of having received, from such officer or other competent Medical Officer during not less than three hours on each of 60 working days, practical instruction in those duties and also those relating to: (*a*) Maternity and Child Welfare Service; (*b*) Health Service for children of school age, (*c*) Venereal Diseases Service; (*d*) Tuberculosis Service; (*e*) Industrial Hygiene; (*f*) Inspection and Control of Food; including meat and milk.

The above certificate (4) must be obtained from a Medical Officer of Health who devotes his whole time to public work, or from a Medical Officer of Health of a Sanitary Area having a population of not less than 50,000, or in Ireland the Medical Superintendent Officer of Health of a County or County Borough having a population of not less than 50,000.

University of Oxford.—The examinations for Diplomas in Public Health have been suspended until further notice.

University of Cambridge.—Two examinations in so much of State medicine as is comprised in the functions of medical officers of health are held during the year. The examination is divided into two parts and demands proficiency in all the branches of study which bear upon the duties of medical officers of health. The examinations in both parts will be oral and practical, as well as in writing. Candidates may present themselves for either part separately; but the result of the examination in the case of any candidate will not be published until he has satisfied the examiners in both parts. Marks of distinction will be placed against the names of candidates who have specially distinguished themselves in either (1) Part I. of the examination; or (2) Part II. of the examination. Candidates must before admission to either part of the examination produce evidence of having satisfied the regulations applicable to Part I. and Part II. The examination for Part I. is in April and for Part II. in October.

For Part I. of the examination courses of lectures and laboratory instruction are given in the University on Hygiene, Chemistry, &c., and on Bacteriology and Parasitology. For Part II. the Medical Officer of Health for Cambridge gives courses on Practical Sanitary Administration and in the Administrative Methods of the Infectious Diseases Hospital; and the Medical Officer of Health to the Cambridgeshire County Council, on Sanitary Laws, School Hygiene, Epidemiology. There are also courses by special lecturers in Vital Statistics, Tuberculosis Service, Venereal Diseases Service, Industrial Hygiene, Maternity and Child Welfare. These courses are open to non-members of the University.

A special Diploma in Hygiene is granted to medical graduates whose qualifications are not registrable in England. The courses and examinations are the same as for the Diploma in Public Health (except that the candidates are not examined in English Sanitary Laws).

All applications for further information respecting examinations and the courses of study should be addressed to Mr. Purvis, Public Health Chemical Laboratory, Cambridge.

University of London.—Candidates for the M.D. Degree may offer State Medicine as a subject in which to graduate. The regulations have been revised and may be obtained on application to the Academic Registrar, University of London, South Kensington.

University of Durham.—The Degree of Bachelor of Hygiene (B.Hy.) and the Diploma in Public Health (D.P.H.).—No candidate is admitted to the final examination for the Degree of B.Hy. unless he is a Bachelor of Medicine and Surgery, of not less than two years' standing, of a recognised University whose degrees are registrable on the books of the General Medical Council of the United Kingdom, and no candidate is admitted to the final examination for the D.P.H. unless he is a registered medical practitioner, of not less than two years' standing. The course of study for the B.Hy. and D.P.H. extends over a period of not less than 12 calendar months, subsequent to the attainment of a qualification registrable by the General Medical Council of the United Kingdom. Candidates for the B.Hy. must attend this course at the University of Durham; candidates for the D.P.H. may attend it at the University of Durham, or at any medical school or institution which is recognised by the University. The examination for the diploma or degree is divided into two parts. A candidate must pass in all the subjects of Part I. before being admitted to examination for Part II. In Part I., and also in Part II., a candidate must pass in all the specified subjects at one time. The examination for Part I. is practical, written, and oral, and includes the following subjects: Bacteriology and Parasitology (including medical entomology); Chemistry and Physics, and Meteorology and Climatology, in relation to Public Health. Candidates are not admitted to examination for Part I. until after they have completed the prescribed courses of instruction in the subjects thereof. The examination for Part II. includes Hygiene and Sanitation (comprising sanitary construction), Epidemiology and Infectious Diseases; Sanitary Law and Vital Statistics; Public Health Administration. The examination is written and oral, and includes practical examinations in Infectious Diseases, Food Inspection, Inspection of Premises—Dwellings, Factories, Workshops, Schools, &c. Candidates are not admitted to examination for Part II. until after they have completed the prescribed courses of instruction in the subjects thereof. Doctor of Hygiene (D.Hy.): Candidates must be Bachelors of Hygiene of the University of two years' standing, and are required to satisfy the examiners that they have conducted original research in the subject of Public Health.

University of Birmingham.—Under the rules and regulations of the General Medical Council the University grants a degree of B.Sc. in Public Health and also a Diploma in the same subject on the following conditions: Graduates in Medicine of this University may become candidates for the degree of Bachelor of Science in Public Health by conforming to all the requirements laid down for candidates for the Diploma in Public Health, except that after graduating in Medicine all courses of study must be taken out in the University, and they must, in addition, have attended a three months' course of Geology in the University. A Thesis on the Ætiology and Prevention of a Disease of which the candidate has made a special study must be submitted on entry for B.Sc. Part II. The examinations will be held in the months of March and October, and will consist of two parts, each part being written, oral, and practical. No candidate will be allowed to pass Part II. until he has passed Part I. Candidates may enter for Parts I. and II. separately or at the same time. The fee for each part of the examination is £6 5*s*. Medical Officers of the Royal Navy who have attended the required course of study at the Naval Medical School, Greenwich, will be admitted to Part I. examinations for the Diploma in Public Health, whether they have previously been students at the Birmingham School or not; and the same applies to officers of the Royal Army Medical Corps who have studied at the Staff College. Medical Officers of the Navy and Army are admitted to Part II. Examination (D.P.H.) on complying with the requirements laid down for attendance upon Courses of Study. These Courses need not necessarily be attended in the University of Birmingham.

University of Liverpool.—The University grants a Degree in Hygiene (M.H.) and a Diploma (D.P.H.), and every facility is afforded for training in Sanitary Science and State Medicine. The curriculum for the Degree extends over a period of two years, the first of which is devoted to laboratory instruction and practical classes (including those for the Diploma); the second being devoted to advanced study and research. The courses may be taken at any time, and students are allowed to work daily in the laboratories.

University of Leeds.—The University grants a Diploma in Public Health, and every facility is afforded for training in Sanitary Science and State Medicine. The examination, which is held twice in each year—namely, in June and December—is in two parts, and is written, oral, and practical. Candidates must pass in Part I. before being admitted to Part II. Instruction in Entomology and Meteorology is given in the first term, and in Sanitary Chemistry and Bacteriology in the second and third terms. Practical work under arrangement with the Leeds City Council. Prospectus can be obtained from the Academic Sub-Dean of the Medical School.

University of Bristol.—Diploma in Public Health. Candidates must be at least 23 years of age, shall be fully registered medical practitioners of not less than two years' standing as such, and shall have passed the examination prescribed by regulations, which can be obtained from the Registrar upon application.

University of Wales.—Candidates for the Diploma in Public Health, the curriculum for which extends over a period of not less than twelve calendar months subsequent to the attainment of a registrable qualification, must produce evidence of having attended for not less than five months at the Welsh National School of Medicine or at an institution approved by the Court, practical instruction in Bacteriology and Parasitology, Chemistry and Physics, and Meteorology and Climatology in relation to Public Health. Candidates must also satisfy the examiners that they have received instruction approved by the University in the Principles of Public Health and Sanitation, Epidemiology and Vital Statistics, Sanitary Law and Administration, and Sanitary Construction and Planning. The candidate must also produce evidence that he has attended for three months on the clinical practice of a hospital for infectious diseases containing not less than 100 beds, and has received therein instruction in the methods of administration, and that he has for a period of not less than six months been engaged in acquiring a practical knowledge of the duties, routine and special, of a public health administration under the supervision of a medical officer of health. The examination for the diploma is divided into two parts, Part I. and Part II., each of which extends over not less than two days. A candidate must pass in all the subjects of Part I. before being admitted to Part II. of the examination. In Part I., and also in Part II., a candidate must pass in all the specified subjects at one time. Part I. of the examination is practical, written and oral, and comprises

Bacteriology and Parasitology (including Medical Entomology); Chemistry and Physics, and Meteorology and Climatology in relation to Public Health. Candidates may not be admitted to Part I. of the examination until they have been certified as having pursued the prescribed courses of instruction in the subjects thereof. Part II. of the examination, which is written and oral, comprises: Hygiene and Sanitation (including Sanitary Construction); Epidemiology and Infectious Diseases; Sanitary Law and Vital Statistics; Public Health Administration. No candidate can be admitted to Part II. of the examination until after the lapse of not less than two years from the date of his obtaining a registrable qualification in Medicine, Surgery, and Midwifery, which qualification must be registered before admission to Part II. of the examination. An examination in each part will be held annually. The examination in Part I. will be held in June, that in Part II. in October. Full information from the Registrar of the University, University Registry, Cathays Park, Cardiff, not later than May 15th for the examination in Part I. and not later than Sept. 1st for the examination in Part II.

University of Edinburgh.—Candidates for the Diploma in Public Health must be graduates in medicine and surgery of the University, or hold corresponding degrees or registrable medical qualifications which must be registered before admission to examination. The course is divided into two parts for which examinations are held twice yearly, in March and July for Part I., and in October and March for Part II. In each part the candidate must pass in all the specified subjects at one examination. Candidates are not admitted to Part II. until they have passed Part I., nor until after the lapse of not less than two years from the date of obtaining a registrable medical qualification. The subjects of the examination are: Part I. (written, oral, and practical), Bacteriology; Medical Entomology and Parasitology; Chemistry, Physics, Meteorology, and Climatology. Part II. (written, oral, and practical), Hygiene, Sanitation, and Sanitary Construction; Epidemiology and Infectious Diseases; Sanitary Law and Vital Statistics; Public Health Administration. There is also included practical examinations in Infectious Diseases, Food Inspection, and Inspection of Premises. The course, which extends over a period of 12 calendar months, begins in October, and provision is made by the University for instruction in all the subjects. Detailed particulars may be obtained from the Dean of the Faculty of Medicine.

University of Aberdeen.—Every candidate for the Diploma in Public Health must be a graduate in medicine of the University of Aberdeen, or of any other University whose medical degrees are recognised as qualifying for registration by the General Medical Council of the United Kingdom. No candidate will be admitted to the Final Part of the Examination for the Diploma until after the lapse of not less than two years from the date of his obtaining a registrable qualification in Medicine, which qualification shall have been registered before such admission. The whole of the prescribed curriculum of study must be undertaken after the candidate has obtained a registrable qualification in medicine, and shall extend over not less than twelve calendar months. At least one academic term must be spent at the University of Aberdeen. Every candidate shall produce evidence of having complied with the following requirements in respect of study and training:—1. Practical instruction in the following subjects within a laboratory or laboratories approved by the University: (*a*) Bacteriology and Parasitology (including Medical Entomology), in relation to diseases of man and diseases of lower animals transmissible to man—at least 180 hours, of which not less than 150 shall be occupied in practical laboratory work; (*b*) Chemistry and Physics, in relation to Public Health—at least 90 hours, of which not less than 70 shall be occupied in practical laboratory work; (*c*) Meteorology and Climatology, in relation to Public Health—at least 10 hours; such instruction to extend over not less than five months or two academic terms. 2. A course or courses of instruction extending over not less than 80 hours dealing with: (*a*) The Principles of Public Health and Sanitation—30 hours; (*b*) Epidemiology and Vital Statistics—20 hours; (*c*) Sanitary Law and Administration (including Public Medical Services)—20 hours; (*d*) Sanitary Construction and Planning—10 hours; such course or courses to be given at an institution or by a teacher or teachers approved by the University. 3. Practical instruction, clinical and administrative, within a recognised hospital for general infectious diseases; such instruction to extend over three months, and to include 30 daily attendances of not less than two hours in each week. 4. Practical instruction and experience, during not less than six months (including attendance of at least three hours on each of sixty working days) in the duties, routine and special, of public health administration, under the supervision of a medical officer of health, who shall certify that the candidate has received from this officer or other competent medical officer, practical instruction in these duties, and also in those relating to: (*a*) Maternity and Child Welfare Service; (*b*) Health Service for Children of School Age; (*c*) Venereal Diseases Service; (*d*) Tuberculosis Service; (*e*) Industrial Hygiene; (*f*) Inspection and Control of Food, including meat and milk. The medical officers of health recognised for this purpose by the General Medical Council are: (*a*) a medical officer of health who devotes his whole time to public health work; or (*b*) the medical officer of health of a sanitary area having a population of not less than 50,000; or (*c*) in Ireland, the medical superintendent officer of health of a county or county borough having a population of not less than 50,000. The examination for the diploma is divided into two parts, each of which extends over not less than three days.

University of Glasgow.—Degree of B.Sc. in Public Health.—Candidates must be graduates in Medicine of a University of the United Kingdom, or of some other University recognised for the purpose by the University Court. Candidates must produce evidence (1) that, after they have obtained a registrable Degree in Medicine, a period of not less than two years has elapsed; (2) that, after they have obtained a registrable degree in Medicine, they have, during a period of not less than 21 calendar months, pursued the course of work and instruction prescribed, and have satisfied the examiners in the prescribed examinations. There are two examinations. Part I. includes the following subjects: (i) Bacteriology and Parasitology (including Medical Entomology); (ii) Chemistry and Physics in relation to Public Health; (iii) Meteorology and Climatology in relation to Public Health; (iv) Higher Chemistry in relation to Public Health; (v) Physics and Geology. A candidate must pass in the subjects marked (i), (ii), and (iii) of Part I. at one examination. Part II. includes the following subjects: (vi) Hygiene and Sanitation (including Sanitary construction); (vii) Epidemiology and Infectious Diseases; (viii) Sanitary Law and Vital Statistics; (ix) Public Health Administration; (x) Applied Hygiene. The examination for Part II. includes practical examinations in Infectious Diseases; Food Inspection; Inspection of Premises, such as dwellings, factories, workshops, schools, and the like. The examination in Applied Hygiene may be on a selected subject professed by the candidate. A candidate must pass in the subjects marked (vi), (vii), (viii), and (ix) of Part II. at one examination. *Diploma in Public Health (D.P.H.).*—Candidates for this Diploma must be legally qualified medical practitioners who are matriculated students of the University. A period of not less than two years must elapse between the attainment by the candidate of a registrable medical qualification, and his admission to the final examination (Part II.) for the Diploma. The candidate must, during a period of not less than 12 calendar months, subsequent to his attainment of a registrable medical qualification, pursue the course of work and instruction prescribed, and pass the prescribed examinations. The examination, which is both written and oral, is divided into two parts, Part I. and Part II., each of which extends over not less than two days. No candidate is admitted to either part of the examination until he has completed the prescribed courses of instruction in the subjects of that part. No candidate is admitted to Part II. until he has passed in all the subjects of Part I., nor until after the lapse of not less than two years from the date of his obtaining a registrable medical qualification, nor unless he presents a certificate showing that his name and qualification have been duly registered in the Medical Register. Part I. includes: (i) Bacteriology and Parasitology (including Medical Entomology); (ii) Chemistry and Physics in relation to Public Health; (iii) Meteorology and Climatology in relation to Public Health. A candidate must pass in all the subjects at one examination. Part II. includes: (iv) Hygiene and Sanitation (including Sanitary Construction); (v) Epidemiology and Infectious Diseases; (vi) Sanitary Law and Vital Statistics; (vii) Public Health Administration. A candidate must pass in all the subjects at one examination. The examination for Part II. includes practical examinations in Infectious Diseases; Food Inspection; Inspection of Premises, such as dwellings, factories, workshops, schools, and the like.

University of St. Andrews.—The Diploma in Public Health is open to those who hold a registered medical qualification of the United Kingdom. The examination is in two parts. (1) (*a*) Bacteriology and Parasitology; (*b*) Chemistry and Physics; (*c*) Meteorology and Climatology. (2) Public Health and Sanitation, Epidemiology and Vital Statistics, Sanitary Law and Administration, and Sanitary Construction and Planning. Before admission to the first examination the candidate must have held his medical qualification for one year, and before admission to the second examination for two years. Graduates in Medicine of the University of St. Andrews may take part or all of the qualifying classes in any University of the United Kingdom, or in any Indian, Colonial, or Foreign University or medical school recognised by the University Court, but holders of other registered medical qualifications must spend at least eight out of the 12 months' curriculum in St. Andrews University. A complete course is given in the Conjoint Medical School, Dundee. The examination fee for each division is £5 5*s*.

University of Dublin (Trinity College).—The Diploma in Public Health is conferred, after examination, under the following conditions. The candidate must be a registered medical practitioner and have obtained a registrable qualification at least two years before the second part of the examination. The candidate must have completed, subsequently to obtaining a registrable qualification, five months' practical instruction in a chemical and bacteriological laboratory, or laboratories, approved by the University, must have received instruction in the following subjects: the principles of public health and sanitation, epidemiology and vital statistics, sanitary law and administration (including public medical services), sanitary construction and planning; must have studied, practically, outdoor sanitary work for six months under an approved officer of health, and must have attended for three months at a fever hospital where opportunities are afforded for the study of methods of administration. A special prospectus may be obtained by application to the Registrar of the School of Physic, Trinity College, Dublin.

National University of Ireland.—At this University there is a Diploma in Public Health, a B.Sc. in Public Health, and a D.Sc. in Public Health.

University of Belfast.—A Diploma in Public Health is given by examination. Every candidate must produce evidence that, after obtaining a registrable qualification, he has during six months received practical instruction in an approved laboratory in which Chemistry, Bacteriology, and the Pathology of the diseases of animals transmissible to man are taught. After obtaining a registrable qualification every candidate must produce evidence that he has attended during three months the practice of a hospital for infectious diseases at which opportunities are afforded for the study of methods of administration. The examination must have extended over not less than four days, one of which shall have been devoted to practical work in a laboratory, and one to practical examination in, and reporting on, subjects which fall within the special outdoor duties of a medical officer of health. The first part of the examination will have reference to the general principles of Sanitary Science and the second part to State Medicine and to the applications of Pathology and Sanitary Science. The examination in both parts is held twice a year, in March and June.

Royal College of Physicians of Edinburgh, Royal College of Surgeons of Edinburgh, Royal Faculty of Physicians and Surgeons of Glasgow.—All candidates for the Diploma in Public Health must have a qualification which has been registered under the Medical Acts. The examination is divided into two parts. For Part I. the candidate must produce evidence of having received during a period of not less than five months at an institution recognised by the Board practical instruction in: (*a*) Bacteriology and Parasitology (including Medical Entomology), especially in their relation to diseases of man and to those diseases of the lower animals which are transmissible to man, during 180 hours, of which not less than 150 hours have been occupied in practical laboratory work; (*b*) Chemistry and Physics in relation to Public Health during 90 hours, of which not less than 70 hours has been occupied in practical laboratory work; (*c*) Meteorology and Climatology in relation to Public Health during not less than 10 hours. For Part II. evidence must be given of having received instruction during not less than 80 hours in: (*a*) The Principles of Public Health and Sanitation for not less than 30 hours; (*b*) Epidemiology and Vital Statistics for not less than 20 hours; (*c*) Sanitary Law and Administration (including Public Medical Services) during not less than 20 hours; (*d*) Sanitary Construction and Planning during not less than 10 hours; of having attended for three months the clinical practice of a recognised hospital for infectious diseases; and of having been engaged during a period of not less than six months in acquiring a knowledge of Public Health administration in addition to practical instruction in the duties relating to: (*a*) Maternity and Child Welfare Service; (*b*) Health Service for Children of School Age; (*c*) Venereal Diseases Service; (*d*) Tuberculosis Service; (*e*) Industrial Hygiene; (*f*) Inspection and Control of Food, including meat and milk. The fee is 12 guineas for both examinations, or 6 guineas for either of them. A fee of 6 guineas is payable by rejected candidates for either examination. The examination is held twice yearly, in March in Glasgow, and October in Edinburgh. The published regulations provide detailed synopses of the subjects of examination. The Registrar for Edinburgh is Dr. David Thomson, 49, George-square, and for Glasgow, Mr. Walter Hurst, 242, St. Vincent-street.

Royal College of Physicians of Ireland and Royal College of Surgeons in Ireland.—Every candidate for the Diploma in Public Health must observe the following rules: 1. A period of not less than two years shall elapse between the attainment by a candidate of a registrable qualification in Medicine, Surgery, and Midwifery, and his admission to the Final Examination for a Diploma in Public Health. 2. The curriculum for a Diploma in Public Health shall extend over a period of not less than 12 calendar months subsequent to the attainment of a registrable qualification. 3. Every candidate shall produce evidence of having attended, during a period of not less than five months, at an institution approved by the Licensing Body granting the Diploma, practical instruction in—(*a*) Bacteriology and Parasitology (*including Medical Entomology*), *especially* in their relation to diseases of man, and to those diseases of the lower animals which are transmissible to man; (*b*) Chemistry and Physics in relation to Public Health; (*c*) Meteorology and Climatology in relation to Public Health. At least 180 hours must be devoted to Course (*a*), of which not less than 150 hours shall be occupied in practical Laboratory work. At least 90 hours must be devoted to Course (*b*), of which not less than 70 hours shall be occupied in practical Laboratory work. At least 10 hours must be devoted to Course (*c*). 4. Evidence of having received, during not less than 80 hours, at an institution or from teachers approved by the Licensing Body granting the Diploma, instruction in the following subjects: (*a*) The Principles of Public Health and Sanitation; (*b*) Epidemiology and Vital Statistics; (*c*) Sanitary Law and Administration (including Public Medical Services); (*d*) Sanitary Construction and Planning. 5. Evidence that he has attended for three months on the clinical practice of a recognised Hospital for Infectious Diseases. 6. Evidence that he has, during a period of not less than six months, been engaged in acquiring a practical knowledge of the duties, routine and special, of Public Health Administration under the supervision of a Medical Officer of Health. The examination for the Diploma is divided into two parts. The examination for Part I. includes Bacteriology and Parasitology (with Medical Entomology); Chemistry and Physics, and Meteorology and Climatology, in relation to Public Health. The examination for Part II. includes Hygiene and Sanitation (with Sanitary Construction); Epidemiology and Infectious Diseases; Sanitary Law and Vital Statistics; Public Health Administration. The examination, which is written and oral, includes practical examinations in Infectious Diseases; Food Inspection; Inspection of Premises—dwellings, factories, workshops, and schools.

PRISON MEDICAL SERVICE.

CANDIDATES for the Prison Medical Service are *approved by the Secretary of State for the Home* Department on the recommendation of the Prison Commissioners. Preference is always given to candidates who have experience of lunacy. Application for employment may be made on a special form, which can be obtained from the Secretary, Prison Commission, Home Office, London, S.W. In the smaller prisons the medical officership is part-time, and is usually filled by practitioners in the locality, preference being given to those who have special experience of lunacy. In the large prisons the medical staff must devote their whole time to the Service. In the case of whole-time service, the appointment is in the first instance to the post of Medical Officer, Class II., and from this rank the Medical Officers, Class I., are selected as vacancies occur. The pay of the whole-time prison medical staff is as follows: Medical Officer, Class II., £350, rising by annual increments of £20 to £000, making the pay at present with bonus £485 8*s*. to £770 7*s*.; Medical Officer, Class I., £050, rising by annual increments of £25 to £800, plus bonus, making the pay £837 5*s*. to £905 11*s*. Unfurnished quarters are provided or an allowance *in lieu is made*. *Study-leave is granted* annually to two of the whole-time Medical Officers. There are 12 full-time medical officers of Class I. and 15 Class II., and 23 part-time medical officers. The number of vacancies is never large and promotion is slow.

DENTAL SURGERY.

REGISTRATION on the Medical Register entitles a practitioner to practise as a dentist, although he cannot register as such without degree or licence in dentistry; but few dental appointments at general or special hospitals or dispensaries are available save to those with a special diploma, and, until registered on the Dentist Register, no dental work under the Additional Benefit Scheme of the National Health Insurance Act can be undertaken.

The Examining Bodies in Dentistry which grant degrees and diplomas in the subject are as follows: Royal College of Surgeons of England, Royal College of Surgeons, Edinburgh, Royal Faculty of Physicians and Surgeons of Glasgow, Royal College of Surgeons in Ireland, and the following Universities: Birmingham, Bristol, Durham, Leeds, Liverpool, London, Manchester, Sheffield, St. Andrews, Dublin (Trinity College), Queen's University of Belfast, and the National University of Ireland. The respective *requirements of the various examining bodies in* dentistry are very similar, being designed to meet the requirements of the General Medical Council, but the examinations vary in stringency, and each school has its rules for matriculation and exemption, and its scale of fees. The student should apply to the secretaries of the various Conjoint Boards or to the Deans of the medical faculties or medical schools for a syllabus.

TEACHING INSTITUTIONS IN DENTISTRY: LONDON.

Royal Dental Hospital of London, School of Dental Surgery, Leicester-square.—A school of the University of London. Women are admitted as students and are eligible for all hospital appointments and school prizes. The school provides the special dental education required by the University of London for the B.D.S. Degree and the Royal College of Surgeons for the Licence in Dental Surgery. The general part of the curriculum may be taken at any general hospital. The hospital is open from 9 A.M. to 5 P.M., there being one staff for the morning and another for the afternoon of each day. *Pupils are received for* the training in dental mechanics recognised by the curriculum. The instructors at the commencement of each session give a course of lectures on Operative Dental Surgery. The five house surgeoncies are held for four months each and are open to all qualified students. The lecturers, in addition to their lectures, give special demonstrations on the Microscopy of Dental Anatomy and Dental Surgery. The lecturer on Dental Mechanics also gives practical demonstrations in the laboratory. There is an Entrance Scholarship in Chemistry and Physics of the value of £25. One Entrance Scholarship in Dental Mechanics and Metallurgy, value £25. Prizes and certificates are awarded by the lecturers for the best *examinations* in the subjects of their respective courses at the end of the summer and winter sessions. For full information as to scholarships and prizes, and other matters connected with the course, application should be made to the Dean.

University College Hospital Dental School, corner of Great Portland and Devonshire-streets, W.—This Hospital and School has recently been thoroughly reorganised, and is now fully equipped with all the most modern appliances. Students are entered as students of University College Hospital, and, as such, attend the classes of Anatomy and Physiology in University College, which is a few minutes' walk from the Dental Department in Great Portland-street, hitherto known as the *National Dental Hospital*, the first Dental School to admit Women Students. Practical courses to comply with the R.C.S. curriculum are held. Clinical Lectures and Demonstrations are given, and each student on entering passes through a preliminary course under a demonstrator. A prospectus containing full information as to lectures, fees, and prizes may be had on application to the Sub-Dean for Dental Students, who attends at University College Hospital Medical School, University street, W.C.1, on Wednesday mornings from 9.30 to 10.30, and at other times by appointment.

Guy's Hospital Dental School.—The work of the Dental Department begins daily at 9 A.M. both in the extraction rooms and in the conservation room. The Extraction Rooms: There is ample accommodation for both general and local anæsthetic extractions, together with waiting- and retiring-rooms. Patients are admitted between 8.45 and 9.30 A.M., and are seen by the dental surgeon for the day, the staff demonstrators, the dental house surgeons, and the dressers. The Conservation Room is open from 9 A.M. till 5 P.M. It affords accommodation for about 100 dental chairs, with the necessary equipment of the most modern type for the use of the Dressers, who, under the supervision of the Staff, perform the various operations of Dental Surgery. There is a separate room for denture patients affording accommodation for 15 chairs and a separate department for children with accommodation for 20 chairs. The Members of the staff attend every morning and afternoon to give demonstrations and otherwise assist students in their work in the Conservation Room and Prosthetic Laboratory. The Probationers' Laboratory is supervised by three of the staff demonstrators, and instruction is given in operative dentistry on a "mannikin" to students during their first three months of clinical study. Students in Dental Prosthetics are received, and a graded, systematic, and full course of instruction, extending over two years, is carried out under the supervision of the Director of the Prosthetic Laboratory, assisted by two demonstrators, a house surgeon, and five mechanics.

Dental students have the opportunity of attending at this hospital the whole course of instruction required by the examining board for the B.D.S. Lond. or L.D.S. Eng.—viz., the complete course in dental prosthetics, the special lectures and practice of the Dental Department, and the general lectures and practice of the Medical School. Students who enter for a medical as well as a dental course are allowed to pursue their study of Dentistry during any period of their medical course most convenient to themselves without further charge.

Twelve house surgeons, 20 assistant house surgeons, and four student demonstrators of Dental Histology are appointed annually. The following appointments are held by students: Full surgeon's dresser, assistant surgeon's dresser, dresser in the children's department, casualty dresser, clerk to the anæsthetist, dresser in the gas extraction and local anæsthetic extraction rooms, and probationary dresser. For particulars as to scholarships and prizes, as well as all information, application should be made to the Dean of the Medical School, Guy's Hospital, London Bridge, S.E. 1.

King's College Hospital.—The Dental School is part of the Medical School of King's College Hospital, and was opened in November, 1923. The Dental Out-patient Department of the Hospital is used for the performance of dental extractions. A large Conservation Room with provision for 40 dental chairs has been equipped. Smaller rooms are used for clinical teaching and administrative requirements, and a specially equipped laboratory for training in the art of dental mechanics. An X ray apparatus has been installed for special use in dental skiagraphy. A museum containing a large number of specimens illustrating oral, buccal, dental, and other diseases is available for teaching purposes. The library, lecture theatre, lecture rooms, common rooms, and the refreshment room are all available for the use of students. Courses of study, including practical work, are provided for the degree of Bachelor of Dental Surgery of the University of London, and for the Diploma in Dental Surgery of the Royal College of Surgeons of England. Special arrangements are made for those students who wish to take a medical degree or qualification in addition to a degree or diploma in Dental Surgery.

The following salaried appointments are open to qualified members of the School: Registrar, Resident House Surgeon, Non-Resident House Surgeon, and Tutors in Dental Mechanics, Orthodontics, and Dental Materia Medica.

Full particulars of the Dental School may be obtained on application to the Dean, or to the Secretary of the Medical School, King's College Hospital, Denmark Hill, London, S.E.

London Hospital.—This school is a part of the London Hospital and Medical College, and is fully equipped on the most modern lines and with the latest appliances. It provides a complete curriculum in all subjects for the B.D.S. Degree and for the L.D.S. Diploma, and is admirably adapted for the purpose of teaching. The Conservation Room is well lighted and ventilated and fitted with pump chairs of the latest pattern; the fountain spittoons at many of the chairs have been specially designed. Each spittoon has attached to it a saliva ejector, hot and cold water, compressed air, gas and electric current, also a swing bracket to carry the students' cabinet. Electric sterilisers are supplied in each department and motor engines where required. The School possesses, in addition to the Theatres, Laboratories, and Museums in the College, a special Museum of Dental Anatomy and Surgery, Operative Dentistry, Prosthetic and Extraction Rooms, and Laboratories for Practical Metallurgy and Prosthesis. A systematic course of instruction is arranged for pupils. The up-to-date Laboratory contains every modern apparatus and is in charge of a skilled curator and his assistants. Connected with the Medical College and Dental School are a Library, Athenæum, Clubs' Union, Dining Hall with moderate tariff, Students' Hostel, and an Athletic Ground. For full particulars as to Scholarships and Prizes, fees and course of study advised, apply to the Dean of the Medical School.

London (Royal Free Hospital) School of Medicine for Women.—Full courses are arranged for women students for the study of dentistry and in preparation for the B.D.S. Degree of the University of London and the Licence in Dental Surgery of the Royal College of Surgeons of England, at the London (Royal Free Hospital) School of Medicine for Women. The Eastman Dental Clinic will, when completed, provide a Dental School for women students; in the meantime the course for dental students is arranged in conjunction with the Royal Dental Hospital.

TEACHING INSTITUTIONS OUTSIDE LONDON.

Birmingham Dental Hospital, Great Charles-street.—Dean: Cyril Howkins, O.B.E., D.S.O., M.R.C.S., L.D.S. The Dental Hospital has accommodation for 100 students. The equipment is in accordance with the most modern requirements for the efficient teaching and practice of Dental Surgery, including Radiology and Ultra-Violet Ray Therapy and a new department for Practical Pathology and Bacteriology. The operations performed annually average 35,000, including gold and other fillings, crowns, bridges, porcelain inlays, and injections for block and infiltration anæsthesia. The orthodontic department is one of the foremost in the country. The Prosthetic and Mechanical Department is large and well lighted and under a highly skilled instructor who is always present. Application for information as to fees and scholarships must be sent to the Dean of the Medical Faculty, Birmingham University, or the Dean of the Dental Hospital, Birmingham.

Leeds University School of Dentistry.—The School of Dentistry is adequately equipped to provide for the complete training of the dental student. It forms a part of the Leeds School of Medicine whilst the instruction in clinical and mechanical dentistry is carried out in the Dental Hospital. The School is now in occupation of a spacious new building especially designed to the requirements of modern dental teaching. The School is also the dental department of the General Infirmary, and its close association with the work of that institution ensures an adequate supply of clinical material, and enables a fuller insight into the position dental surgery holds in relation to general medicine and surgery, especially with regard to the major diseases and injuries of the head and neck. The courses of study are mainly designed to meet the requirements of the B.Ch.D. and L.D.S. Leeds, but every opportunity is afforded to students preparing for the degrees or diplomas of other licensing bodies. Full-time demonstrators give the instruction in clinical dental surgery, prosthetic dentistry, and mechanics, which is carried out under the supervision and direction of members of the Honorary Staff, two of whom are in attendance each day. Special facilities are provided for instruction in Orthodontia, Dental Radiography, Local and General Anæsthetics. Prizes are offered for competition to pupils and students in their respective years of study. Communications should be addressed to the Warden, School of Dentistry, Leeds, from whom a prospectus may be obtained.

Dental Hospital of Manchester.—This hospital is in association for teaching purposes with the University of Manchester and the Royal Infirmary, and is in the centre of a very large population. Courses of study are provided to meet the requirements of the various examining bodies, including those of the University of Manchester for the qualifications L.D.S. and B.D.S., and the L.D.S. of the Royal College of Surgeons of England. *Clinical instruction is given* in Dental Prosthetics, Operative Dentistry, Diagnosis and Extraction, Orthodontics, Dental Surgery, Radiography, and Anæsthetics by specially appointed Clinical Teachers.

All the courses of instruction are open to women students. Copies of the Prospectus will be forwarded on application to Mr. J. Hilditch Mathews, Dean.

Newcastle-upon-Tyne Dental Hospital and School.—This hospital is centrally situated (within five minutes of the various colleges, infirmary, and railway station); the rooms are well lighted and thoroughly equipped for carrying on the work. Dental surgeons and an anæsthetist attend each morning. A tutorial dental surgeon is also in attendance. Medals and Certificates of Merit are granted to students showing certain standards of proficiency in the various classes at the Dental School. The prospectus of the Dental Hospital and School, containing full information, may be obtained from Mr. James Coltman, 18, Ellison-place, Newcastle-upon-Tyne, Dean.

Devon and Exeter Dental Hospital, 24, Southernhay West, Exeter.—The hospital is open on Mondays, Tuesdays, Wednesdays, Thursdays, Fridays, and Saturdays, and patients are admitted between the hours of 9.30 and 11 A.M. Students attend the practice of the hospital under the control of the medical officers.

SCOTTISH TEACHING INSTITUTIONS.

The Incorporated Edinburgh Dental Hospital and School.—The Edinburgh Dental Hospital and School is located in spacious and well-equipped buildings at 30, 31, and 32, Chambers-street, and offers special advantages to dental students. A large and important extension of the existing buildings has now been opened. The General Courses required for the Dental Diploma may be taken in the Medical School of the Royal Colleges of Physicians and Surgeons or in the University schools. The general hospital attendance and clinical instruction are taken at the Royal Infirmary. The University, Medical Schools, and Royal Infirmary are within three minutes' walk of the Dental Hospital. The special courses are taken in the hospital. The Dental Hospital practice, extending over two years, affords a student ample opportunity for a full acquaintance with every branch of dentistry. The hospital admits a limited number of indentured pupils. They receive their instruction in Mechanical Dentistry concurrently with the general and special courses. A premium of 60 guineas is payable with each such pupil. The practice and lectures of the hospital are recognised by, and qualify for, all the Licensing Boards. Those students who desire to take a Medical and Surgical Diploma in addition to the L.D.S. have in this school admirable facilities for so doing. The triple qualification of the Royal College of Physicians and Surgeons of Edinburgh and the Royal Faculty of Physicians and Surgeons of Glasgow is recommended. The Higher Dental Diploma (H.D.D.) of the Royal College of Surgeons affords an opportunity of obtaining a higher qualification subsequent to registration. The Prospectus, with full information, may be obtained by application to the Dean or the Assistant Secretary.

Incorporated Glasgow Dental Hospital, 158, Renfrew-street and 15, Dalhousie-street, Glasgow.—The School is open to Men and Women Students, and Lectures are given on Dental Surgery, Operative Dental Surgery, Orthodontia, Dental Anatomy and Physiology, Dental Histology, Dental Mechanics, Crown and Bridge work, Dental Metallurgy, Dental Bacteriology, Radiology, Anæsthetics, and Dental Materia Medica. Lectures on general subjects required for Dentistry may be taken at the University or at one of the extra-mural schools where special provision is made for Dental Students. A new mechanical laboratory with bench accommodation for 60 pupils and fully equipped with the most modern appliances for teaching practical dental mechanics has recently been added. Full information may be had on application to the Dean.

Glasgow Royal Infirmary (Dental Department).—The following course in the curriculum can be taken at St. Mungo's College: Anatomy, six months; Practical Anatomy, nine months; Physiology, six months; Chemistry, six months; Practical Chemistry, three months; Surgery, six months; Medicine, six months; Materia Medica, three months; Dental Surgery, six months, and attendance for two years on the dental department of the hospital. Clinical Medicine (three months) and Clinical Surgery (six months) are taken at the Royal Infirmary.

IRELAND.

Incorporated Dental Hospital of Ireland, Lincoln-place, Dublin.—All Dental Students who have passed their Second Dental Examination in the Royal College of Surgeons in Ireland (or an equivalent examination or examinations) are admissible to the Clinical Instruction of the Hospital. In addition to Clinical Instruction and Special Demonstrations, courses of lectures are given at the hospital on Dental Surgery and Pathology, Mechanical Dentistry, the Administration of Anæsthetics, Orthodontia, Dental Anatomy, and Dental Materia Medica, and instruction in Anæsthetics. The course in practical Dental Mechanics can be taken in the Hospital Laboratory. Further particulars can be obtained from the Dean.

Births, Marriages, and Deaths.

BIRTHS.

McELLIGOTT.—On August 9th, at "Namona," Arnos-grove, Southgate, N.14, the wife of Dr. E. T. McElligott, of a son.

MARRIAGES.

JAUCH—IRMLER.—On August 28th, 1929, in London, F. Jocelin Jauch, M.B., B.S., F.R.C.S., to Irma C. J. Irmler.

PARKER TUPLING—SEDGLEY.—On August 1st, at St. Stephen's, Dulwich, Leslie Parker Tupling, M.R.C.S., L.R.C.P., to Daphne, youngest daughter of Mr. and Mrs. Ernest Sedgley, of Dulwich.

DEATHS.

BELL.—On August 21st, at 18, Ullet-road, Liverpool, as the result of an accident, Florence (Fon), the loved wife of Professor W. Blair Bell.

N.B.—A fee of 1s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

BRITISH MEDICAL ASSOCIATION.

ANNUAL MEETING IN MANCHESTER.

(Continued from p. 389.)

SECTION OF PHYSIOLOGY AND BIOCHEMISTRY.

THE PLACE OF HUMAN PHYSIOLOGY IN THE TRAINING OF MEDICAL STUDENTS.

Opening Address.

WITH Prof. J. A. MILROY (Belfast) in the chair, a discusssion on this subject was opened by Prof. F. R. FRASER (London), who said there could be no better definition of the human physiology of to-day than that given by Haldane in 1916: "A new physiology which teaches what health really means, and how it maintains itself under the ordinarily varying conditions of the environment." This in turn depended on a definition of "health" and an appreciation of "the normal." For these human physiology must largely concern itself with the interaction of systems, therein differing from most animal physiology which was analytical. To-day a physician should ask to what extent and in what directions his patient's adjustments to his environment were disturbed, and when he found the cause of the maladjustment, if it be not removable, he helped the sufferer back to normality. Text-books of medicine gave a very false impression of its practice. "That awful word syndrome" dominated them, and pigeon-holing was emphatically not the best practice of medicine. The need of study of the individual as a whole rather than analytically had become increasingly apparent during the war.

Human physiology should be taught to the student before he came to the wards, partly because clinicians, though improving in this respect, were still rather inclined to ignore it. On the other hand, it was difficult for the student to understand man's adjustments and reactions until under the guidance of the clinician he saw the breakdown. The institution or addition of a course of human physiology in the final year of the medical curriculum had this objection, that it suggested that the lessons were something different and apart from the practice of medicine, and that the whole subject of physiology could be taught in the wards. As regards the physiology of the pre-clinical years, it must be remembered that these were years of scientific education, and that courses should not be altered to the detriment of their value as scientific training. Certainly the clinician could never take it all over; he had already too much to do. The physiologist must anticipate the clinician, and the clinician try to follow the lines of the physiologist. Too often the clinician, successful socially, did not seem to the student to follow a physiological or indeed any logical line of argument. Again the heads of physiological departments, for all their eminence, could not deal with semi-clinical problems, and the teacher must, indeed, be an investigator of his subject if his work was not to be dry as dust.

The reports of the Medical Research Council suggested great improvements in the teaching of physiology during the last ten years. For further progress there must be more coöperation between the physiology departments and the wards. Young clinicians should serve in the laboratory after their house appointments, but when they become consultants it was very difficult for them to continue to do any physiology. If only the heads of the departments would get together the younger men would follow. To allow time for this the heads must be relieved of excessive routine, in both teaching and administration. The discussion, Prof. Fraser thought, should deal with the following three practical points: (1) at what time or times in the curriculum is human physiology to be taught? (2) who can best teach it?; and (3) how may one best provide for its further investigation?

Dr. C. G. DOUGLAS (Oxford) said that to many a student physiology was a task imposed upon him which delayed his entry into the wards. The student saw no value in physiology apart from its clinical application, and much physiology is not so directed. That a student should think he could deal with the abnormal without an adequate study of the normal excited Dr. Douglas's apprehension as much as his amazement, yet the fault was not entirely the student's. The problem in medical education thus raised was solved by human physiology, which had altered the student's outlook and for which we have learned new methods which enable us to appreciate the close functional linkage of the systems of the body. Time should be devoted to the subject early in the student's career to ensure the getting of his interest, and thereafter the facts of the text-books stood out in a new light. For example, for a lecturer who cares to take the trouble the changes in the body as a result of exercise could be presented as a living subject, and the student, having grasped the principles, could easily fill in the details from text-books. Practical work was as yet more difficult and lagged far behind the lecture course, but recent biochemical advances, which were mainly quantitative, were a great help. The student was keen about facts which he could verify on himself, whereas elementary experiments on the heart, muscle, and nerve of the frog were mere exercises, and never aroused his interest in the slightest degree. When the student, in the speaker's experience, came to think of the organism as a comparative whole, quantitative work, normally considered tedious, became intensely interesting. In particular the fascinating field of the physiology of the sense organs could only be explored in man.

Dr. Douglas said he would emphatically dissent from the view that such work was too difficult for the pre-clinical years. Its introduction, which had changed listlessness into interest, should be at the beginning of the study of physiology, when it would attract the student's attention. The training should be continued through the clinical years to connect the work with medicine. Though we were bound to draw some of our conclusions from the effects of disease the student's interest should be focused on the normal—too much abnormal would merely confuse him. The development of a "synthetic view" would lead to improved treatment instead of mere diagnosis.

Sir HUMPHRY ROLLESTON, speaking as a member of the G.M.C., which body, he said, was too often thought of as merely inquisitional, asked if it were wise to separate human physiology in any way from physiology as a whole. There was the danger of its dropping behind clinical investigation, when advances which were at the time apparently devoid of practical application became later of great importance. He thought the physiologists might adapt the methods of instruction and illustrate them by cases from the wards. Where human histology differed from that of the cat and dog human material should be used. It should be remembered that physiology merged into experimental pathology and pharmacology, and clinical teachers should have one foot in each department. In hospitals without the clinical unit system the pathologist might teach human physiology—he hoped that the demand for teaching would create the supply. He would like to see the physician at the post-mortem table—the physician's operating table—forecasting what was there before the pathologist began, though at present this might only lead to a contest of wits. The course of physiology might be spread over the whole of the student's time or the teaching be given at two periods, first as now and again just before graduation. He then read a contribution to the discussion by Prof. Joseph Barcroft in which details of the instruction in human physiology in Cambridge were given, and which, while supporting the point of view of the opening speakers, emphasised the value of what was to be learnt from the study of evolution and the primitive forms of life.

Prof. B. A. MCSWINEY (Leeds) said that he had been struck by the keenness and enthusiasm of his students in the "human" part of their course. He believed in the correlation of animal experimentation and the study of human function. It was important *that the student should learn to realise normal* variations. In the past physiology had not been a sufficient bridge between biology and clinical work. The biochemical aspect required further development. Instructors in human physiology should have a clinical outlook, but in hospitals there was a lack of laboratory accommodation and facilities, and too much of the work was done as a routine by the officers of the institution. Facilities for the hospital staff should be provided in the physiology department, but the present hospital system was not good for coöperation, because of the clashing interests of the L.S.D. of consultant practice with the time demanded for research and teaching. Hospitals should have officers trained in and for experimental medicine, who would work both in the laboratory and in the wards. This would guarantee the supply of clinical material for the students. As regards the argument that the curriculum is already overcrowded, we had not removed as we had added, and a radical pruning was necessary.

Dr. J. A. RYLE (London) said that the younger clinicians who had had a physiological training really did explain symptoms instead of eliciting them. All medical registrars and clinical tutors should have had a laboratory training in research, and such training was now regarded as necessary for appointment to the staff of a clinical unit. He had been much refreshed by a paper by Dr. Batten in THE LANCET of June 15th, dealing with clinical physiology and the "limits of the normal." There was much bad medicine because of isolated tests of function—a radiologist might report a "dropped stomach" in a perfectly healthy person. Closer coöperation between medicine and physiology would, in his opinion, be better than a special department of human physiology, and the medical unit was a great help for the coöperation required. Even the occasional appearance of the physiologist in the wards would be most helpful.

Dr. F. W. LAMB (Manchester) described the course which he had developed during the last seven years, which started with the biological and physical characteristics of blood, and thence led to its carriage of gases, circulation in the human subject, and respiration. The sense organs were also investigated. In the course, which continued after the physiology professional examination and through the years of clinical study, he collaborated with his clinical colleagues, giving instruction on dyspnœa, cyanosis, and the special senses from a physiologist's point of view. He was emphatic that human physiology should be treated as a science subject, not as a means to a penny-in-the-slot diagnosis for physicians, and that it should be taught as a distinct course though in close relation to experimental and chemical physiology. Human physiology was the true synthetic physiology, the integrating factor to the student, and his students were so keen that he could not get them out of the laboratory at the end of the day. He regarded lectures on human physiology as absolutely essential, there being no adequate text-book, and the monographs and papers being too much for a student to master by himself.

Prof. A. V. HILL (London) said that he agreed very largely with the previous speakers, and always regarded Dr. Lamb as the apostle of human physiology. He thought it would be a calamity if the head of a physiological department had to be a medical man—as well insist on a professor of physics having passed through the engineering shops. He gave the human physiologists a motto: "Don't do bad experiments on man in place of good experiments on animals."

Dr. H. WHITRIDGE DAVIES (Leeds) said that he had worked with students from the point of view of experimental medicine, for which the student's methods were not good enough, and from the point of view of physiology, in which he tried to fit students for clinical research. Where there was no medical unit there was no conception in the wards of analysis. The indication to students of suitable courses of special reading was much appreciated. He thought the idea of experimental medicine greatly increased the student's interest, but that the physiologist should *not come to the wards unless he is prepared to come* every day.

Dr. C. G. IMRIE (Sheffield) regretted the absence of Prof. Leathes, who had developed a valuable fourth-year course. He thought that it was in the wards that human physiology was appreciated, and that a new generation of clinicians was required for the desired progress and coöperation.

Prof. H. S. RAPER (Manchester) said that the pre-clinical period should be reserved for pure science, but that the student's mind would be better orientated if he got the bile and pepsin he used, not from bottles, but from the natural source, and if he did his urine analyses on his own 24-hours specimen. He regarded a full-time physiologist as a necessity on a hospital staff—even such clinicians as Horsley and Rose Bradford could not latterly keep pace with the growth of physiological knowledge.

Prof. MILROY said that he had got more help from his colleagues in physics and chemistry than from the clinical side. There should be a department of applied physiology as there was of applied biochemistry. He would plead that the present demands on students were too severe and feared the diet offered exceeded the assimilation capabilities.

Prof. FRASER, in reply, again stressed the necessity of coöperation between the heads of departments, and regretted that there had been no *practical* suggestions as to improvements in teaching in the clinical years.

Dr. DOUGLAS, in his reply, explained that in Oxford human physiology was not taught till the second year of the physiology course, which was a mistake, but that there physiology was taught as a pure cultural science, not as a pre-clinical training.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED AUGUST 17TH, 1929.

Notifications.—The following cases of infectious disease were notified during the week: Small-pox, 120 (last week 114); scarlet fever, 1688 (last week 1482); diphtheria, 844; enteric fever, 90; pneumonia, 504; puerperal fever, 43; puerperal pyrexia, 110; cerebro-spinal fever, 17; acute poliomyelitis, 12; acute polio-encephalitis, 1; encephalitis lethargica, 17; dysentery, 4; and ophthalmia neonatorum, 100. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the Metropolitan Asylums Board on August 20th–21st was as follows: Small-pox, 147 under treatment, 1 under observation (last week 132 and 5 respectively); scarlet fever, 1314; diphtheria, 1483; enteric fever, 14; measles, 318; whooping-cough, 251; puerperal fever, 25 (plus 11 babies); encephalitis lethargica, 123; and "other diseases," 23. At St. Margaret's Hospital there were 10 babies (plus 5 mothers) with ophthalmia neonatorum.

Deaths.—In the aggregate of great towns, including London, there were no deaths from small-pox, 1 (0) from enteric fever, 27 (7) from measles, 5 (1) from scarlet fever, 17 (5) from whooping-cough, 22 (3) from diphtheria, 60 (10) from diarrhœa and enteritis under two years, and 20 (5) from influenza. The figures in parentheses are those for London itself.

Of the deaths from diarrhœa and enteritis under two, 9 were reported from Birmingham, 6 from Liverpool, and 4 from Hull. Liverpool recorded 4 deaths from measles and 4 from whooping-cough.

The number of stillbirths notified during the week was 252 (corresponding to a rate of 30 per 1000 total births), including 47 in London.

THE Medical Research Council issued at the end of last week the results of a series of studies on binocular vision, undertaken at the Royal Naval College, Greenwich, by Instructor-Lieutenant-Commander N. M. S. Langlands, R.N. Commander Langlands's work has extended over several years, special facilities for carrying it out having been granted by the Admiralty.

PUBLIC HEALTH AND LOCAL GOVERNMENT.[1]

THE state of the public health for 1928 is summarised in the annual report of the Chief Medical Officer of the Ministry of Health which is published this week. In an introductory chapter Sir George Newman sets out, always clearly and often eloquently, certain fundamental information which is necessary for a reasonable understanding of the chapters which follow. For the Report submits an extraordinarily varied body of information and opinions, as might be expected when we consider the simple yet complicated, the separate and yet connected conditions which go to make up society to-day, and when we recognise at the same time that those conditions, because the nation remains young and lively are often new, and yet, because we are an old people, often have their roots in a remote ancestry. The introduction is, in a sense, a sequel to the essay which prefixed Sir George's Annual Report last year,[2] in which he set out the principles which should guide forthcoming changes in local government. This year he proposes to help the public to form a sound judgment and, as far as may be, an estimate of the position of our public medicine, such a bird's-eye view enabling the reader to gauge the value of the different detailed communications as well as to understand how these form component parts of one work.

The sum of the responsibilities of the Minister, as defined by the Ministry of Health Act, 1919, are: "to take all such steps as may be desirable to secure the preparation, effective carrying out and coördination of measures conducive to the health of the people," and the first of these duties is the prevention and cure of diseases. The main part of the Annual Report, as might be expected, deals with these steps under such headings as general epidemiology, the incidence during the year of influenza, cancer, tuberculosis, and venereal disease; and those who have followed the reports of the medical officers of health of the various sanitary districts for the year in question will be prepared to find, with respect to the last two, that the tidings are good. The chapter on tuberculosis is far ranging, taking note of the progress of tuberculosis work as carried out in dispensaries and residential institutions, of the influence of the Act of 1929 on the development of tuberculosis schemes, of the value of after-care and of technical education, and, among special points, of the efficacy of Prof. Calmette's method of immunisation, the fate of young children in tuberculous households, and of tuberculosis in relation to occupation, the example here being the incidence of the disease on printers. The standard death-rates for tuberculosis of the respiratory system show that the gross death-rate from pulmonary tuberculosis in males has fallen from 1233 per million to 879, and in females from 900 to 641 since 1911, while the reduction in non-pulmonary tuberculosis, attacking both sexes, is even more striking. These figures may be said to justify the general opinion that notification of tuberculosis is year by year becoming more effective. The chapter dealing with the incidence of venereal disease is, on the whole, happy in its message. Although the returns from the treatment centres for 1928 show only a decrease of 2·7 per cent. in new cases of syphilis, against which has to be set off an increase of 9·9 per cent. in cases of gonorrhœa, the improvement in the ratio of females to males, which emerged from the figures last year, has been maintained, and there is distinctly greater promptitude in seeking treatment.

Two sections of the report call especially for mention—viz., the incidence of small-pox and the whole subject of maternity. In 1928 there were 12,428 cases of small-pox, most of them extremely mild, but 53 deaths were attributed to the disease. Seventeen of the victims were unvaccinated, 28 had been vaccinated in infancy only, and the vaccination of the remainder was doubtful. Cases occurred in every English county except Rutland, Westmorland, Cumberland, and the Isle of Wight. There were, however, some 2000 fewer cases than in 1927, and nearly 4000 fewer in the county of Durham, where the disease has for some years been prevalent. Many of the cases were at first mistaken for influenza. The report observes that even in Jenner's day some cases were so mild that children ran about the streets with the rash on them, and sees no reason to think that we have recently been dealing with a disease specifically different from small-pox. Where the disease is vigorously attacked it is controllable, but mild cases are frequently overlooked, and the infection spreads. The relative immunity of London is a remarkable fact for which there is no explanation. The introduction by the *Tuscania* on April 1st, 1929, of a severe type of small-pox called for vigorous action, which was so successfully carried out that only six secondary cases developed, and at the expiration of six weeks or so there was no infection of the *Tuscania* strain in the country.[3] The episode is noted in the Report although, not strictly speaking, belonging to the year 1928.

Much attention was paid during 1928 to the high mortality which still attends the process of childbirth; 2920 women died and an enormous number were invalided, while about 43,000 children died during their first year of life. The maternal mortality-rate of 4·42 per thousand births was the highest on record, and there is no doubt that much of the mortality and morbidity was preventable. Two official committees are exploring the problem. Pending the result of their inquiries Sir George makes trenchant remarks. First, he notes that many pregnant women are not making use of the facilities already provided for them. Secondly, he points out that many local authorities are not vigilantly engaged in perfecting every branch of their maternity service, and are not closely coördinating these branches into one unified attack on the problem. Merely to provide facilities is not enough. It is for the local authority to see that the provision it makes is effectively coördinated.

Another prime duty of the Minister of Health, as defined under the Health Act, is "the collection, preparation, publication, and dissemination of information and statistics," and Sir George's Report discharges the responsibility of the Minister succinctly, while many of the facts and figures of the Report speak for themselves. The birth-rate for the year was 16·7, a greatly reduced number, which is accompanied by a substantial saving of child life. Children are decreasing in proportion to the whole population, while the number of persons over 55 is increasing. The death-rate was 11·7 per thousand persons. The birth-rate thus exceeded the death-rate by 5 per thousand, and we seem to be within sight of a stationary population. In 1928, the country saved 41,500 babies' lives, over and above the average annual saving during the first ten years of the century. The incidence of sickness, apart from infectious disease, cannot be estimated except from the returns of insurance practitioners. These indicate that during the year the nation lost a total of 20¼ million weeks' work among the insured population to whom sickness benefit was payable—that is, among a very small proportion of the nation. In the list of diseases responsible for the loss of work among these people, respiratory maladies easily take the first place, accounting for some 30 per cent. They are followed by irregularities of the digestive system, injuries, lumbago, and rheumatism and septic conditions. The chief causes of death were diseases of the heart and circulation (23 per cent.), respiratory diseases

---

[2] THE LANCET, 1928, ii., 875.

[3] The new Vaccination Order, which is the result of the work of the Rolleston Report, was discussed in our columns last week.

(13 per cent.), cancer (12 per cent.), diseases of the nervous system (9 per cent.), and tuberculosis (8 per cent.). These five conditions, accounting for 65 per cent. of the death-rate, are the outstanding physical scourges which we have to combat to-day. The year 1928 was exceptionally healthy.

An outstanding event of the year on the administrative side was the preparation of the Local Government Act. The Report discusses carefully the new duties laid upon the County Medical Officers of Health, and the Principal Medical Officer has no doubt that the reforming Act offers big potentialities if it is administered carefully. Also he sees no reason why the magnificent tradition of the voluntary hospital should not become widely established in municipal hospitals free from the taint of pauperism. He advises the municipal hospitals to imitate all that has proved good in the voluntary hospitals, and urges mutual coöperation. The great essential here is the preservation of the integrity of the medical profession; prevention and cure and their respective exponents must not be divided. So long as no one comes between the doctor and his patient all will be well, *and local authorities ought to be trusted to see* that such interference never takes place. In this country, the principle of local self-government has been generally recognised as the essence and genius of our national vigour. Our public health work is safeguarded by a comprehensive system of law, by-law and regulation, exercised by central and local authority working together, administered partly by a number of elected voluntary representatives and partly by a substantial number of medical advisers and trained sanitary and health officers. The chief business of the Ministry of Health is unification and coördination; its chief purpose is to secure sound national progress. This progress will be made certain in proportion as the State, the doctor, and the public work along right lines harmoniously.

We shall deal with the Report in further detail in subsequent issues.

Medical News.

MEDICAL SOCIETY OF LONDON.—A programme for the first half session 1929-30 has been issued. Mr. Donald Armour will deliver a presidential address entitled Some of Lettsom's Contemporaries on Oct. 14th. Mr. Hayward Pinch and Prof. Sidney Russ will open a discussion on Radium Therapy on Oct. 28th. On Nov. 11th a discussion on the Relative Value of the Different Methods of Diagnosis in Gastric Disease will be introduced by Dr. J. A. Ryle, Dr. Harrison Orton, and Prof. E. C. Dodds, and a discussion on the Treatment of Head Injuries by Mr. Wilfred Trotter on Dec. 9th. Sir John Thomson Walker will give the Lettsomian lectures on Enlarged Prostate and Prostatectomy, and Sir Arthur Keith the Annual Oration on Modern Medicine and Evolution.

Sir George Newman, who has been since 1910 a Crown Representative for England on the General Medical Council, has been re-nominated for a further term of five years from Oct. 9th next.

THE Medical Research Council announce the receipt from Mrs. Odo Cross of a sum of £10,000 as the endowment of a trust for the establishment of research *fellowships in the study of tuberculosis, to be known as the* "Dorothy Temple Cross Research Fellowship Fund."

Dr. W. E. Gye writes to disclaim responsibility for statements contained in a Sunday newspaper of August 25th concerning his work on cancer. It is true, he says, that a somewhat lengthy paper is in preparation, but the suggestion that he has something new and "sensational" to report is a guess and is untrue.

THE RADIUM HOSPITAL FOR WOMEN.—It is *expected that this hospital will be opened in September by* Madame Curie. It is housed in the former residence of the late Mr. John Petrie, R.A., in Fitzjohn's-avenue, Hampstead, which has been converted by Mrs. Elizabeth Scott, the architect. The large and lofty studio has been made into the chief ward and holds 16 beds; other small wards accommodate another ten beds. It is hoped to build another ward over the studio with X ray and other necessary equipment. The medical staff consists entirely of women.

Notes, Comments, and Abstracts.

THE TECHNIQUE OF STUDY.

BY G. F. WALKER, M.D., M.R.C.P.,

MEDICAL TUTOR AND REGISTRAR IN THE UNIVERSITY OF LEEDS, AND THE GENERAL INFIRMARY AT LEEDS.

To add one single drop to the torrent of written and spoken advice which almost overwhelms a medical student at varying phases in his career requires explanation. I am emboldened to submit the following notes because, while still retaining vivid memories of the doubts and difficulties of my own student days, I find myself engaged in tutorial work in a large teaching hospital. Much of what follows has necessarily been gleaned from my own teachers quite recently, and I hereby make acknowledgment, but some, I trust, is new.

Personal Factors.

"The first wealth is health." Medical students are far too ready to slump into a condition of middling physical health. A reaction against the athleticism of some public schools tends to set in early, forcibly and far too frequently when undergraduate life is reached. But sound physical health is all-important and must be maintained. The rich opportunities given by University or community life for the preservation of physical fitness should be exploited fully. Indeed, a certain portion of each week and each year should be set aside exclusively for recreation. Of collateral importance is the development of mental stamina. This term is comprehensive and includes not only the acquisition and maintenance of will and judgment, remote alike from rashness and pusillanimity, nor merely the ability to sacrifice the present to the future, but also the cultivation of the gentler arts of this world. Medicine may be a jealous mistress, but he who gives her his all will never experience the content and philosophical security which a broad general culture imparts. In the years of student-life time must be found for the study of a science for its own sake—any particular field of study such as astronomy or theology or any subject which happens to appeal to the individual—or for the cultivation of literature or an art. In this connexion must be mentioned the necessity for travel in the student years. Many great cities of Western Europe are cheaply and easily accessible and should be visited in the holidays. If these cannot be reached then—speaking to Leeds students—Edinburgh, York, and London must suffice. During these tours, whether at home or abroad, there can be no harm in visiting the hospitals and schools, but any attempt at promiscuous study should be firmly suppressed. But I have not forgotten that the medical student has to study medicine, and all through the student years the habit of study has to be diligently cultivated.

The Technique of Study.

Much knowledge has to be acquired in a relatively short time. It is necessary, for instance, to know that the islets of Langerhans are not in Polynesia. But this loading up with necessary facts is by no means the hardest or the most important part of the curriculum. Of much greater importance is the acquisition of technical skill, dexterity, practical experience, and clinical acumen. Of greater importance still is the keeping of a proper perspective during the various stages and appointments of the curriculum as will appear. In reading and practical work every student should periodically examine his methods of study, ruthlessly scrapping unprofitable habits and customs. Reading should be done in the evening. And the minute technique of reading is worth more than scanty consideration. At the very outset the student should decide whether he remembers best by merely looking at the written word, or by writing it down personally, or by hearing it spoken. That is to say, he should decide whether he has a "visual" memory or an "auditory" memory. The former is fortunately the more common, but no general rule can be laid down. By actual experiment every student must investigate his powers of memory, decide his own classification, and work on it. Once the most favourable channel for reception of facts is decided upon details of study can be regulated. Study from books should be done with elbows on the table. It should be done in privacy and in an environment conducive to alertness and clarity. Anything conducive to too much physical comfort must be shunned. No attempt should be made to read soon after a meal or when tired. Reading in the train or 'bus, or "at any old time," is waste of energy and promotes staleness. As a general rule, if the practical work of a working day has been faithfully performed, two hours' book work in the evening is ample, and it is then that reading should consolidate and fix the practical work done during the day. Therefore it should be an inviolable rule that whatever has been seen or heard in the lecture-room, laboratories, or wards during the day should have first claim on the time available for reading during the evening. Surgery must be read during the performance of surgical appointments, ophthalmology while the student is actually seeing ophthalmic patients, and so forth. It is worse than useless to attempt to acquire the formal dogmas of medicine by suddenly beginning at page 1 in a large text-book. The greater part of each morning and afternoon should be devoted to practical work and training. The surpassing value of dissection, of study in the wards, out-patient department, and receiving-room, of lectures which flavour facts with a lecturer's personal experience, and particularly of the "writing-up" of patients' records, needs no emphasis. It may be taken for granted that a "part" once thoroughly dissected is etched deeply in the memory. Similarly, a scientific or clinical investigation once thoroughly performed repays the investigator many times over by conferring ineradicable knowledge. In dissecting the student should display the region so that he can subsequently recall it in three dimensions. And in investigating patients, when once the full straight facts have been clearly displayed, the imagination should be invoked to illuminate the patients' own side of the problem. For the precise and formal extraction of data about a patient I know of no more pithy and significant advice than the exhortation "Look and see," and the cultivation of sincerity and the preservation of an ever open mind should be comprised in that advice. Further, the technique of practical study needs as much watchful care as does the technique of reading. It is very easy during the clinical years to be in a place where work can be done, should be done, and is in fact being done—by others. The tendency to lapse into intellectual somnolence during demonstrations is very insidious in its onset, but a habit of vigorous, enthusiastic attention is not difficult to acquire, and, when once acquired, being seldom lost, should be striven for. The mere acquisition of the habit is worth while for its own sake; its utility will probably outlive the utility of many of the topics to which it is first applied. A large teaching hospital usually abounds in places where dawdling is possible and prevalent, and which need not be specified.

Here are two little pieces of advice. First, the midday meal should be taken free from "shop." Secondly, the notebook is worth consideration—a good small loose-leaf notebook should accompany the student through his whole curriculum; it should be just small enough to fit in the pocket, it should be available at all times, and each night it should be tidied up and full pages withdrawn to be placed in appropriate accumulations.

The Course as a Whole.

The really fundamental thing to grasp is that the course *is* a whole and not a string of loosely connected segments each requiring a concentrated onslaught with subsequent relegation to the background. I do not mean that a student should attempt to go forward three steps at a time, but I do mean that he should look upon his curriculum as a series of phases of initiation into the science and art. Each phase prepares the student for subsequent phases, but is very dependent for its full consummation on preceding phases. To reduce this to practical terms it may be said that anatomy and physiology should forthwith be continuously studied during clinical work. And other examples will readily occur. It follows from the fact of the unity of the course that the text-books of each phase should be retained and kept viable during subsequent phases. Revision and maintenance of knowledge is much safer and easier if done from the actual pages of the big text-book used during the phase when it was intensely studied. I say "big" text-book, because one big text-book should be selected for each topic and adhered to from start to finish. The small summaries and cram books have their place, but they are mainly useful as a help to marshal facts. The author of a most successful synopsis, far from making the usual claim to be meeting a "long-felt want," says in his preface that ultimate reliance on anything but the larger books will lead to failure. Just as the text-books of successive phases should be carefully retained throughout, so must the microscope not be sold. Being "historically minded" is valuable. I do not mean that the shelves should be laden with large text-books on the history of medicine, but the bald facts of study can be enlivened by reference to an encyclopædia when a proper name is found. And from time to time monographs such as Flint's "The Heart: Old and New Views," should be perused.

Examination Incidents.

It is quite useless to ignore the fact that examinations loom largely in the curriculum. I have many times told my student friends that the examination incidents—and I am convinced that "incident" is the right word—should be happy little episodes. This information has always evoked incredulity and sometimes less amiable emotional reaction, but on several occasions graduates have subsequently admitted personal verification. Of course, no one but a fool would make light of examinations. Indeed, they should be taken very seriously; so seriously that the student, immediately he enters a particular phase, should plan out his work for the terminal examination of that phase by actual time-table and schedule. He should record diagrammatically his progress through the phase so that the work is spread out evenly over the time available. As a crude example let us suppose that a phase of study in one of the ancillary subjects lasts six months and that the text-book concerned is 500 pages in thickness. Then 100 pages must be covered each month by schedule, the actual pages being selected each evening according to the nature of the particular lecture, demonstrations, and practical work enjoyed during the day. In short, I am back at the platitude that the art of passing examinations consists in doing steady comprehensive work during the whole of the antecedent phase. The corollary to this is that he who works steadily in the practical work of a phase with concurrent systematic reading cannot be "ploughed."

Vacancies.

For further information refer to the advertisement columns.

Albert Dock Hospital, Connaught-road, E.—M.O. At rate of £110.

All Saints' Hospital, 91, Finchley-road, N.W.—Jun. H.S. Also Asst. H.S. At rate of £150 and £100 respectively.

Aylesbury, Royal Buckinghamshire Hospital.—Res. M.O. At rate of £180.

Ayr County Hospital.—2 H.S.'s. Each at rate of £150.

Beckenham Urban District Council.—Part-time Asst. M.O. £325.

Birmingham and Midland Eye Hospital, Church-street.—H.S. £110.

Bolingbroke Hospital, Wandsworth Common, S.W.—H.S. At rate of £120.

Bootle Borough Hospital, Derby-road.—Hon. Laryngologist and Aurist. Also Jun. M.O. At rate of £125.

Bournemouth, Royal Victoria and West Hants Hospital.—2nd H.S. At rate of £120.

Bradford Children's Hospital.—H.S. and H.P. Each £120.

Bradford, Royal Eye and Ear Hospital.—Jun. H.S. £120.

Brighton, Royal Alexandra Hospital, &c.—H.S. At rate of £100.

Calcutta, Presidency College, Bengal.—Prof. of Physiology. Rs. 1000.

Cambridge, Addenbrooke's Hospital.—Res. Anæsthetist. At rate of £180. Also H.P. and H.S. Each at rate of £130.

Cambridge, Papworth Village Settlement.—H.P. At rate of £100–£200.

Central London Throat, Nose, and Ear Hospital, Gray's Inn-road, W.C.—Hon. Chief Clinical Assts.

Dreadnought Hospital, Greenwich.—H.P. and H.S. Each at rate of £110.

Exeter, Royal Devon and Exeter Hospital.—H.P. Also Asst. H.S. At rate of £130 and £120 respectively.

Fulham Maternity and Child Welfare Clinics.—Part-time M.O. 1½ gns. per session.

Leeds Maternity Hospital.—Hon. Obstetric Surgeon.

Leeds, St. James' Hospital.—H.P. and S. £200.

Liverpool, Royal Children's Hospital.—Res. H.P. Also H.S. Each at rate of £60.

Liverpool, St. Paul's Eye Hospital.—H.S. £100.

Liverpool, Walton Institution, Rice-lane.—Res. Asst. M.O. £200.

London Lock Hospital, 91, Dean-street, W.—H.S. At rate of £200.

London University.—William Julius Mickle Fellowship. £200.

Maidstone, Kent County Ophthalmic and Aural Hospital.—Aural H.S. At rate of £200.

Manchester, Monsall Hospital for Infectious Diseases.—Jun. M.O. £350.

Manchester Royal Eye Hospital.—Jun. H.S. £120.

Margate, Royal Sea Bathing Hospital.—H.S. At rate of £100.

Middlesex County Council.—Asst. County M.O.H. £750.

Newcastle-upon-Tyne City Mental Hospital, Gosforth.—Jun. Asst. M.O. £350.

Northampton General Hospital.—H.P., H.S., and Asst. H.S. Each at rate of £150.

North Middlesex Hospital, Edmonton, N.—Anæsthetist. 2½ guineas per session.

Norwich, Jenny Lind Hospital for Children.—Res. M.O. £120.

Otago and Dunedin University Hospital, New Zealand.—Sen. Res. M.O. £500.

Queen Charlotte's Maternity Hospital, Marylebone-road, N.W.—District Res. M.O. Also Asst. Res. M.O. Each at rate of £80.

Radcliffe-on-Trent, Notts County Mental Hospital.—Jun. Asst. M.O. £350.

Richmond Royal Hospital, Surrey.—Jun. H.S. £100.

Rochester, St. Bartholomew's Hospital.—H.P. At rate of £175.

Royal Liverpool Babies' Hospital.—Res. M.O. At rate of £90.

Royal Northern Hospital, Holloway, N.—H.P. Also Obstetric H.S. Each at rate of £70.

R.S.B.H. Offices, 15, York Buildings, Adelphi, W.C.—H.S. At rate of £100.

Southampton, Royal South Hants and Southampton Hospital.—Jun. H.S. Also Cas. O. At rate of £130 and £120 respectively.

Swansea Hospital.—Sen. Res. M.O. Also H.S. £300 and £150 respectively.

University College Hospital, Gower-street, W.C.—Asst. Radiologist. £200.

Walsall General Hospital.—Res. Surg. O. At rate of £200.

Watford, Herts, Peace Memorial Hosp.—Res. M.O. At rate of £150.

Lettsomian Lectures

ON THE

RELATIONSHIP OF DERMATOLOGY TO OTHER BRANCHES OF MEDICINE.

Delivered before the Medical Society of London

BY H. W. BARBER, M.B. CAMB., F.R.C.P. LOND.,

PHYSICIAN IN CHARGE OF THE SKIN DEPARTMENT, GUY'S HOSPITAL.

LECTURE II.*

I PROPOSE in this lecture to discuss the significance and nature of a group of eruptions provoked by micro-organisms or toxins, which reach the skin via the blood stream. For the sake of clarity, I would suggest for this group the generic name of the *exanthematides*. This term indicates a relationship with the exanthemata of the specific fevers, which is undoubted, and at the same time possesses the termination "ide," which has been commonly accepted for some of the eruptions under consideration—e.g., the tuberculides, syphilides, trichophytides, and leprides.

If, after excluding the specific fevers, one surveys the list of general infective diseases associated with cutaneous manifestations, two are outstanding by reason of their ubiquity, their serious nature, their chronicity, and the amount of accurate knowledge that has accumulated concerning them; these two diseases are tuberculosis and syphilis. They have dominated medical thought and research for generations; they still dominate dermatological thought and research throughout the greater part of the world.

Less obviously of interest to dermatologists is another group of diseases, which the general physician has labelled "rheumatic." But if tuberculosis and syphilis belong in great part to the domain of dermatology, the rheumatic diseases, especially, perhaps, rheumatic fever, also have cutaneous manifestations, which are not only of interest to physicians and dermatologists alike, but are in my opinion so closely akin in their mechanism of production and significance to certain tuberculous and syphilitic eruptions, that they enable us to draw deductions of the highest importance.

Since Poynton and Paine[1] in 1900 presented their thesis that rheumatic fever is due to streptococcal infection, evidence has gradually accumulated that both this condition, as well as certain other forms of rheumatic disease, are of streptococcal origin. Although I have reviewed a great deal of the experimental work that has been carried out in recent years on the pathogenesis of rheumatic fever, I am obviously not fitted to express an authoritative opinion on the streptococcal theory of its causation. Whether, however, one accepts the specificity of the particular strain or strains of streptococcus, isolated by Small[2], by Birkhaug,[3] and by Lazarus-Barlow,[4] or whether with Swift[5] and his co-workers one believes, as seems more probable, that the pathogenesis of the disease depends on the existence in certain persons of a condition of allergy to various strains of streptococci, resulting from repeated low-grade infections or the existence of chronic foci of infection, the evidence that like tuberculosis and syphilis, rheumatic fever is allergic in nature, and that the streptococcal group of organisms is responsible seems to me overwhelming. This evidence is based on clinical, pathological, bacteriological, and experimental findings, and I have yet to hear any argument to the contrary that will bear examination.

Swift[6] in America, and Bezançon and Weil[7] in France, have drawn striking comparisons between the various manifestations of rheumatic fever with those of tuberculosis and syphilis.

To quote Swift, Derick, and Hitchcock:—

"In all three diseases there is usually an initial lesion, which, when present, is followed shortly by distinct enlargement of the satellite lymph nodes. In all, the serious manifestations occur at a distance from this lesion, and usually are multiple in distribution. In tuberculosis, although the majority of the population is infected, only relatively few persons ever show clinical symptoms. In both rheumatic fever and tuberculosis a rise in the standard of general living conditions has been accompanied by a decreasing incidence of the diseases. A number of workers have called attention to a similarity in the familial incidences of these two infections. In all three diseases there is a decided tendency to relapses, which seems to be due to a breakdown of a partial immunity. In all the histopathological pictures of the typical lesion is that of a granuloma, the histogenesis of which in tuberculosis and syphilis has been definitely proven to be allergic in nature. This allergic lesion can be considered an effort on the part of the body to restrict the activity of the micro-organism to these local areas. The tubercle has the same general characteristics throughout the life of the individual, although there may be special features of the tuberculous infection in certain tissues or organs. While the different syphilides may seem to have decidedly different characteristics, these variations may be considered quantitative rather than qualitative. In both tuberculosis and rheumatic fever the presence of lesions in the walls of the serous cavities or joints is accompanied by the outpouring of serofibrinous exudate. In both rheumatic fever and syphilis there is a marked tendency to focal endo- and perivascular involvement; and both infections are prone to attack the heart. It is true that differences can be found in the three diseases; but it is in these differences that there reside the features which bring about the peculiar pictures of the respective maladies. Indeed, in individual cases it is sometimes difficult to decide whether one or another type of infection is active until specific differential diagnostic measures can be applied."

It is my general agreement with this thesis that has led me to sunbmit a comparison between certain cutaneous manifestations of tuberculosis and syphilis together with those of the severer forms of ringworm infection on the one hand, and of rheumatic or streptococcal infection on the other. All those eruptions may, I think, be conveniently classed together as the exanthematides.

A. THE SYPHILIDES.

In the average case of untreated syphilis there is:—

(1) A period of incubation, about three weeks in duration, between contamination and the appearance of the *primary lesion*.

(2) A primary period during which the spirochætes multiply locally, invade the lymphatics and glands, thence to reach the circulation, but the Wassermann reaction is negative; this is also about three weeks in duration.

(3) A second incubation period, again of about three weeks, between the first appearance of a positive Wassermann reaction and the development of the secondary eruptions—*the secondary syphilides*. With these the Wassermann reaction is at its height. The various forms of secondary syphilide become successively less extensive, but larger in size, and the Wassermann reaction also tends to diminish in intensity.

(4) With the subsidence of secondary manifestations, there may be a period of freedom from symptoms, and the Wassermann reaction may become latent or actually negative.

(5) Finally, there is the *tertiary* period, when the large nodular gummata represent the cutaneous manifestations, and the Wassermann reaction is found positive in from 60–80 per cent. of cases.

As in the specific fevers, there is thus an incubation period during which time a state of allergy towards the infecting virus is developing, and the secondary syphilides, corresponding to the exanthematous rashes, represent allergic reactions of the skin against the spirochætes reaching it via the blood stream, such reactions having for their object the destruction of the organisms in situ. This question will be discussed more in detail in connexion with the tuberculides and trichophytides.

B. THE TUBERCULIDES.

Although tuberculosis cannot so readily as syphilis be divided into primary, secondary, and tertiary periods, nevertheless such a division can be made, and the cutaneous manifestations of the two diseases be very closely compared. In the vast majority of cases, infection with the tubercle bacillus takes place via the digestive tract—mouth, nasopharynx, or small intestine—thence reaching the lymphatic system. As Calmette[8] has clearly shown, the view, still widely held, of a primary "chancre of inoculation" in the lung ("lesion of Parrot and Kuss") is open to serious criticism. Very occasionally, however, a true primary tuberculous chancre of the skin may occur, comparable to the primary sore of syphilis, and to that evoked by the experimental inoculation of the skin in animals. Holt[9] has collected 41 cases, including one under his own observation, in which the primary chancre developed on the penis of infants after ritual circumcision by a phthisical rabbi, and of these 16 are known to have died. Milian and Brocq have recorded two examples on the lips, and Bruusgaard has studied seven cases. From the primary lesion the neighbouring lymphatics and glands are invaded, and the Pirquet reaction becomes positive in from 12 days to some weeks. Boeck[10] and Bruusgaard[11] have seen an eruption of lichen scrofulosorum, with a phlyctenular keratitis, develop six weeks after the healing of such a chancre on the finger (compare with a secondary syphilide).

---

* Lecture I. appeared in THE LANCET of August 24th.

In 1896, Darier[12] proposed the term "tuberculides" for a group of eruptions occurring in frequent association with evident manifestations of tuberculosis. Considerable discussion has naturally taken place, as to what are and what are not tuberculides. The list suggested by Darier himself in the last edition of his Précis, is as follows:—

(A) *Cutaneous Tuberculides.*—The situation of the lesions is dermo-epidermic in the following forms of tuberculide.

(1) *Lichenoid.*—Lichen scrofulosorum.

(2) *Papulo-necrotic.*—Folliclis; acnitis of Barthélemy.

(3) *Acneiform.*—Acne cachecticorum of Hebra (a simple variety of (2).

(4) *Lupoid.*—Benign sarcoid or lupoid of Boeck. Lupus pernio.

(5) *Erythemato-atrophic.*—Lupus erythematosus—fixed type.

(6) *Erythematous.*—Exanthematous lupus erythematosus: tuberculous form of erythema perstans.

(B) *Hypodermic Tuberculides.*—The situation is in the subcutaneous tissue. These are represented by the tuberculous form of erythema induratum (Bazin's disease), the subcutaneous sarcoids of Darier-Roussy, and the disseminated nodular sarcoids, all of which are probably merely varieties of the same type of lesion. Erythema nodosum probably should be included in some cases.

Of these every one is agreed as to the claims of lichen scrofulosorum, the papulo-necrotic varieties (folliclis, &c.), and at any rate the majority of cases of Bazin's erythema induratum. While most dermatologists consider that in some instances lupus erythematosus is of tuberculous origin, Schaumann[13] prefers to class it, not with the tuberculides, but, in association with lupus pernio, the sarcoids of Boeck, and the malignant lymphogranuloma of Sternberg, as a cutaneous manifestation of paratuberculosis, due to the filtrable form of the tubercle bacillus. In addition, erythema nodosum and erythema multiforme are considered by some to be toxi-tuberculides in certain cases.

Pathogenesis of the Tuberculides.

A great deal of very careful experimental work has been carried out in connexion with the pathogenesis of the tuberculides, and it has thrown much light on the phenomenon of allergy, and on the part played by the skin in the defence of the body as a whole. Briefly, the salient points may be summarised as follows:—

The clue to the nature of the tuberculides is provided by the phenomenon described by Koch[14] in 1891. As is well known, the subcutaneous inoculation of virulent tubercle bacilli into a susceptible animal like the guinea-pig is followed after 10–15 days by a nodule which ulcerates—the tuberculous chancre—comparable to the primary sore of syphilis, and identical with that occasionally met with in young children, not previously infected with tubercle, as already stated. This experimental chancre persists, and in it the bacilli multiply, invade the lymphatics and glands, and eventually produce a generalised visceral tuberculosis, affecting chiefly the liver and spleen, from which the animal dies. If the guinea-pig be reinoculated at another point in the skin before its death—preferably 4–6 weeks after the primary inoculation—with living or dead bacilli, an inflammatory hæmorrhagic lesion is rapidly formed, which breaks down, scabs over, and, unlike the primary chancre, heals, leaving a scar. In it the newly inoculated bacilli are destroyed, and there is no invasion of the adjacent lymphatic glands. This is the so-called Koch's phenomenon, and the lesion resulting from the second inoculation represents a defensive reaction against the superinfection (Calmette), and is comparable to certain forms of tuberculide as they occur in human beings. As Sequeira[15] puts it, the tuberculides are spontaneous examples of Koch's phenomenon.

Gougerot and Laroche,[16] Lewandowsky,[17] and others may be said to have produced tuberculides experimentally, the two first mentioned by rubbing the epilated skin of guinea-pigs, *previously tuberculised*, with emulsions of living and dead bacilli, Lewandowsky by inoculating bacilli directly into the left ventricle or veins. The lesions thus produced correspond clinically and histologically to human tuberculides—particularly of the papulo-necrotic type.

The explanation, then, of the tuberculides usually given is that in a person, already sensitised to tubercle—i.e., in a state of allergy, and with an active tuberculous focus, such as lymphatic glands—there occurs a bacteriæmia with dead or attenuated bacilli, and these, coming to rest in a small dermic or hypodermic vessel, provoke a local inflammatory tissue reaction of the tuberculoid type, which has for its object the destruction of the embolised bacillus, and is thus a protective mechanism. This would explain why bacilli are so seldom demonstrable in the lesions, and why animal inoculation with material from them so often fails; nevertheless, in recent lesions bacilli have been found, or successful inoculations have been made by several observers in lichen scrofulosorum, papulo-necrotic tuberculide, erythema induratum, lupus erythematosus, and in the lupoids of Boeck. Moreover the injections of tuberculin into a person with active tuberculosis may provoke an outbreak of tuberculides—e.g., lichen scrofulosorum, erythema induratum, and when such are already present, marked focal reactions occur.

It will be seen that in the mechanism of their production the tuberculides resemble the secondary and tertiary eruptions of syphilis, since they represent allergic reactions of the sensitised skin or subcutaneous tissue against tubercle bacilli circulating in the blood stream.

C. THE TRICHOPHYTIDES.

In 1912, Jadassohn,[18] and later Guth,[19] Sutter,[20] Bloch,[21] Rasch,[22] Pulvermacher,[23] Jessner,[24] Ambrosoli,[25] Bruusgaard,[26] and others, described a variety of *generalised* eruptions that might occur as a result of a local infection of the skin with ringworm fungi, when such infection caused an inflammatory reaction of sufficient intensity. Following Darier's terminology, these eruptions are called trichophytides, microsporides, and favides, according to the type of ringworm fungus responsible. For the sake of convenience I shall include them all under the name of trichophytide. They are exactly comparable to the syphilides and tuberculides. As in the majority of cases of syphilis, there is a primary lesion in the skin, which develops at the site of inoculation of the fungus. As a result of this, the skin as a whole may become sensitised, so that, should dissemination of the fungus or of its toxin through the blood stream occur, the secondary eruptions—trichophytides—result from their contact with the sensitised skin. It is only, however, in the severer forms of suppurative ringworm—usually of animal origin—that these secondary eruptions are likely to be met with. I believe that Neisser and Plato[27] in 1902 were the first to prepare an extract from ringworm fungi, which they named trichophytin, and which is analogous to tuberculin. They found that in cases of deep-seated ringworm—i.e., those in which there is a marked inflammatory reaction—the injection of this trichophytin provoked a general reaction with rise of temperature and constitutional symptoms, together with a local reaction at the site of injection and a focal response in the area of infection. Normal controls, patients with other diseases, and those suffering from the *superficial* forms of ringworm, gave no local or general reactions. Since then a good deal of experimental work has been carried out along similar lines. Briefly it may be said :—

(1) That a deep-seated ringworm in man, or an experimental infection with certain species of ringworm in animals, may produce an allergic state, so that general and focal reactions result from injection of trichophytin, and positive cutaneous or intracutaneous tests with this substance may be obtained, which persists for years after the infection is cured.

(2) In animals a lasting immunity to reinfection results. In man, a reinoculation produces a short-lived lesion, comparable to that arising from a second inoculation of tubercle bacilli in Koch's phenomenon. Clinically, a deep-seated ringworm produces a very considerable degree of immunity in the sense that second attacks are very rare ; this is probably due to cutaneous allergy, which causes rapid destruction of the reinoculated fungus, rather than to true immunity.

(3) It has been shown by Bloch, first, that animal immunity to ringworm can only be produced by inoculating the skin, subcutaneous or intraperitoneal inoculations being ineffective ; secondly, that in a sensitised person the sensitiveness is in the skin-cell itself, for by transplanting two pieces of skin, one from a sensitised and one from a non-sensitised person, on to a normal person, the piece from the sensitised person, after the graft had healed, gave a positive cutaneous reaction to trichophytin, whereas the other piece and the subject's own skin gave negative results.

(4) As a result of suppurative ringworm infection (most commonly in trichophytosis) there may occur generalised eruptions—the trichophytides, microsporides, and favides—accompanied sometimes by fever, enlargement of the lymphatic glands and spleen, swelling of the joints, and a polymorphonuclear leucocytosis. In some cases these eruptions are due to dissemination of the fungus spores through the blood stream, since the fungus has not only been successfully cultured from deep-seated nodular or papular trichophytides by several observers, but also from the circulating blood itself by Ambrosoli and by Jessner. In some cases, however, these general eruptions may result from exogenous spread from the primary site of infection by the lymphatics, for example, as in the corymbose forms ; or from the action of trichophytin on the sensitised skin-cells, since Bloch produced first a scarlatiniform erythema and later a typical lichenoid trichophytide by injection of trichophytin in a boy who had had a severe ringworm infection, but was cured.

We thus see how very closely in their pathogenesis the syphilides, tuberculides, and trichophytides are related. These infections may result in a high degree of allergy, whereby the tissue-cells, particularly of the skin, become sensitised, so that when the dissemination through the blood stream of the infective organism, or, in some cases, of its toxin—e.g., tuberculin and trichophytin—takes place, a variety of eruptions—or cutireactions—occur, representing defensive reactions against superinfection, and resulting in the destruction of the organism or toxin in situ.

D. THE STREPTOCOCCIDES.

Some years ago, at a combined discussion on focal infection in relationship to dermatology, I proposed the name "streptococcides" to designate certain eruptions that I believed to be allergic reactions to streptococcal infection, and comparable to the tuberculides, syphilides, and trichophytides, and I drew up a comparative list, showing how the same type of cutaneous or subcutaneous reaction might result from these four infections. Unfortunately, Sabouraud[13] has recently employed the same word in a different sense, to indicate certain *external* streptococcal infections of the skin, and this is to be deplored, since, in my opinion, the termination "-ide" should be reserved for allergic reactions to micro-organisms or toxins reaching the skin via the blood stream.

The majority of the eruptions that I have labelled streptococcides belong to the erythema group, and include some like erythema multiforme and erythema nodosum which have long been noted to occur in association with rheumatic fever, or, like lupus erythematosus, with chronic rheumatoid arthritis.

Now the dermatologists are in exactly the same position vis-à-vis the eruptions I term "streptococcides" as the physicians are with regard to rheumatic fever, and for the same reason. Tuberculosis, syphilis, and ringworm are well defined and established diseases, and a definite diagnosis of one or the other can usually be substantiated. But the streptococcal group of organisms, some strains of which are normal saprophytes that are ever with us, is in a state of flux ; strains that are in the laboratory apparently identical may have entirely different pathogenic properties, and a human being may die of one that is relatively innocuous to a mouse. It is often, therefore, impossible to furnish definite proof that a given condition is due to streptococcal infection, however strong the presumptive evidence may be, and it is almost as dangerous to draw conclusions from the effect of this or that method of treatment, as it is to infer that, because a pathogenic strain of streptococcus is found in some obvious focus of infection, it is necessarily the cause of a given symptom. Nevertheless, I believe the establishment of a group of streptococcides is justified by the evidence that has accumulated from independent sources during the last few years, evidence that is at least as strong as that upon which the theory of the streptococcal origin of rheumatic fever is based. If we accept it, then, just as Swift and others have drawn a comparison between tuberculosis, syphilis, and rheumatic fever as regards their evolution, and their clinical and pathological pictures, so may we compare the cutaneous manifestations of such well-defined infections as tubercle, syphilis, and ringworm with those of the less tangible streptococcal infections. The great interest of such a comparison lies in this fact, that, with certain types of cutaneous or subcutaneous reaction, not only are the clinical appearances much the same whatever organism is responsible, but the histological pictures are similar in form, showing that the various defensive allergic reactions to infective organisms may depend rather on the tissues affected than on the nature of the infection.

I emphasise this point because, although I agree with Adamson in believing that such distinctive eruptions as lichen planus, psoriasis, and pityriasis rosea must be due each to its own specific micro-organism, this view cannot, in my opinion, be maintained in the types of eruption we are now going to consider. They are, as Darier puts it, *syndromes* that may be provoked by more than one infection, their different morphological and pathological characters depending on the anatomical structures involved and in their situation, and not on the infecting organism responsible for them. Darier, for example, points out that not only may a lichenoid follicular syphilide be clinically identical in appearance with lichen scrofulosorum, but that histologically it may be impossible to differentiate between the two. On the other hand, the same infection may produce two or more of these eruptions at one and the same time.

NATURE OF THE ERUPTIONS.

Let us now consider seriatim some of these types of eruption—the exanthematides as I have called them. Their nature is indicated in Table I.

(1) *The Lichenoid Eruption.*

This is a polymorphic eruption consisting of small papules, some plane like those of lichen planus, but the majority follicular, varying in colour from pale yellowish-brown to bright red. The follicular papules may be capped by a horny scale or plug (one form of lichen spinulosus), or by a vesico-pustule. This form is represented, as will be seen in the table, by lichen scrofulosorum, the lichenoid trichophytide or microsporide, and by the lichenoid follicular syphilide.

Type of eruption.	Syphilides.	Tuberculides.	Trichophytides.	Streptococcides.
Papular lichenoid, usually follicular.	Lichenoid follicular syphilide.	Lichen scrofulosorum.	Lichen trichophyticus.	Lichenoid follicular eruption—e.g., in association with streptococcal impetigo.
Eczematoid.	—	Dermatitis scrofulosa (eczema scrofulosorum).	Eczematoid trichophytide.	Eczematoid, or frankly eczematous dermatitis associated with focal streptococcal infection.
Erythema multiforme.	(?)	(?)	Erythema multiforme trichophyticum (Bloch, Rasch).	Most cases of erythema multiforme of the classical and particularly *of the recurrent type.*
Erythema nodosum.	Doubtful.	Yes.	Yes (Bloch, Sutter, Pulvermacher, Bruusgaard.	Probably the great majority of cases.
Erythema circinatum.	Circinate tertiary syphilide.	Yes. (Darier.)	—	Erythema annulare centrifugum.
Erythema scarlatiniforme.	—	(?)	Yes. (Sutter, Bloch.)	Erythema scarlatiniforme recurrens. Scarlet fever.
Erythema induratum.	Yes. (Ravaut, Tzanck and Pelbois, Pautrier and Darier.)	True Bazin's disease.	—	Non-tubercular form (Whitfield) "Nodosités rheumatismales."
Lupus erythematosus.	(?) according to some authors.	Yes.	—	Yes.

Now Whitfield[29] was, I believe, the first to describe an eruption occurring in association with streptococcal impetigo, usually, but not necessarily secondary to pediculosis capitis. Let me quote his own admirable description:—

> "The first sign to be added to those of the simple impetiginous lesion is the eruption of extremely fine miliary papules, situated at the orifices of the hair follicles of the sides of the back of the neck extending down nearly to the clavicles. These papules appear to be produced by the erection of the hair follicles, and are at first slightly if at all reddened. They may remain in this stage until they subside, or they redden and even become covered with minute vesicles, though this is uncommon. They resemble closely, except as to situation, the papules of lichen scrofulosorum."

It will be seen how nearly the description corresponds to that of the lichenoid tuberculide, syphilide, or trichophytide. I have recently seen a patient with a widespread streptococcal impetigo of the face and neck; on stripping him, there was found on the back and chest an ill-defined erythematous eruption, associated with groups of tiny follicular papules. At his second visit, when his impetigo had almost subsided, all trace of this secondary eruption had disappeared.

(2) *The Eczematoid Eruption.*

There has been considerable discussion as to whether one is justified in describing an eczematoid tuberculide—the eczema scrofulosorum of the older authors. In 1920, Attwater, Marshall and I[30] described a series of cases of an eczematoid dermatitis, occurring almost exclusively in children and adolescents as scaly patches of a characteristic fawn or pale brown colour, usually dry, but sometimes oozing—probably as a result of scratching or rubbing—and situated chiefly on the extensor surfaces of the limbs, the trunk, and on the face, particularly on the temples and forehead below the margin of the hair.

In about 80 per cent. of the cases described Marshall and Attwater were able to demonstrate definite signs of active tuberculosis. I christened the eruption "dermatitis scrofulosa." In 1926, Dowling and I[31] described a further series of these cases, and we showed (1) that exactly similar patches may arise de novo, and persist for some time in tuberculous children at the sites where Pirquet's cuti-test with tuberculin has been done, and (2) that in children with dermatitis scrofulosa patches identical in appearance and histological structure with those already present may be produced by applying tuberculin to the skin. We also observed cases of undoubted lichen scrofulosorum, in which patches of dermatitis scrofulosa were coexistent, and put forward the view that the latter is an eczematoid variety of the former. I am also of the opinion that the so-called "fausse teigne d'Alibert" is merely dermatitis scrofulosa occurring on the scalp.

Some years ago a child whom I had treated in infancy for eczema was brought to me for scaly patches on the limbs and trunk, which were characteristic of dermatitis scrofulosa, accompanied by slight generalised enlargement of the lymphatic glands. The practitioner in charge of the case was entirely sceptical of my opinion that the child had active tuberculosis, but a week later there occurred an outbreak of typical lichen scrofulosorum, and the late Dr. J. J. Perkins confirmed the diagnosis of tuberculous adenitis.

Hügel, Eliaschoff, and Schaumann[32] have recorded cases of lichen scrofulosorum in which the normal papular eruption was associated with "brownish red scaly patches of psoriasiform aspect." Schaumann found in microscopical sections infiltration with epithelioid and giant cells around the follicles.

Comparable to dermatitis scrofulosa is, I think, the eczematoid trichophytide described by Jadassohn and Guth, and the eczematoid microsporide by Finnerud.[33] It is generally agreed that they are varieties of the lichenoid trichophytide or microsporide, just as dermatitis scrofulosa may be regarded as a variety of lichen scrofulosorum. I believe that these eczematoid eruptions are due to the sensitisation of the epidermal cells to the toxins—tuberculin and trichophytin respectively—and the artificial production of dermatitis scrofulosa by applying tuberculin to the skin is in favour of this view. The other tuberculides and trichophytides, with the possible exception in some instances of the lichenoid varieties, are, of course, held to result from embolism of the actual organism, dead or living, and not to their toxins.

Can we recognise a comparable eczematoid streptococcide? I think we can with reasonable certainty. Whitfield remarks in his description of the lichenoid eruption associated with streptococcal impetigo of the scalp:—

> "In some cases the secondary eruption is limited to this, but in others there occurs, after a variable number of days, an acute outbreak all over the chest, abdomen, and shoulders of an annular or figurate erythematous eruption with secondary scaling, such as would be classed in the ordinary way as a circinate seborrhœic eczema of the trunk."

This description tallies exactly with the description of eczematoid trichophytide and microsporide given by Guth and Finnerud respectively.

Like dermatitis scrofulosa this toxic eruption must be distinguished from the scaly, dry form of impetigo. Moreover, Whitfield,[34] Sutton,[35] Visher,[36] myself and others have drawn attention to eczematous eruptions associated with focal sepsis elsewhere—e.g., in the teeth or tonsils—in which the infective organism responsible usually seems to be a streptococcus.

To sum up—generalised eruptions of the lichenoid and, to a great extent, follicular variety, may occur in syphilis, tuberculosis, and trichophytosis, and, as a variant, an eczematoid form of dermatitis due to epidermal sensitisation can be recognised in the last two; eruptions similar in type occur in cases of focal streptococcal infection in the skin itself or elsewhere.

(3) *Erythema Multiforme.*

Unfortunately, the term erythema multiforme has been, and still is, used loosely to designate a variety of erythemato-urticarial and sometimes purpuric eruptions occurring, for example, after the ingestion of certain foods or drugs, and the injection of foreign sera. I would restrict it to an eruption which possesses definite enough clinical features, although few, I think, would claim it to be ætiologically specific.

Clinically, it is characterised by a symmetrical eruption of nummular erythematous papules, usually when fully developed of a characteristic dark lilac hue in the centre, pink or vermilion red at the periphery. To the touch they give a curious sensation like that of a rubber cap stretched over the mouth of a bottle full of fluid.

Numerous variations from this simple lesion may occur; thus the central portion may disappear leaving a ring (erythema annulare) which by excentric spread and intersection with similar rings may produce gyrate figures (erythema gyratum). Owing to the intensity of the serous exudation, vesicles or bullæ may form in the centre, and around these arise rarely the multi-coloured rings—erythematous or vesicular—giving the variety known as erythema or herpes iris; or from actual hæmorrhage the lesions may be purpuric.

The distribution is almost invariably the same, the backs of the hands, wrists and forearms, the elbows and knees, the dorsa of the ankles and feet, and the face being the sites of election. Sometimes the palms and soles are involved, the thick horny layer in these situations somewhat obscuring the characteristics of the papules. True erythema multiforme is one of the relatively few eruptions that affect the mucous membranes, particularly those of mouth, conjunctiva and vulva, and probably of the stomach and intestines, in view of the acute gastro-intestinal crises, so well described by Osler, that may rarely accompany the eruption.

Ætiology.—Excluding the rare cases of apparently classical erythema multiforme provoked by certain foods and drugs, and by infections such as gonorrhœa and enteric, or occurring after vaccination, we may say that several observers have stressed its association with manifest tuberculosis, and both Bloch and Rasch have described typical outbreaks in the course of suppurating ringworm, although at least one of Bloch's cases is open to question. But in the vast majority of cases of true erythema multiforme the eruption, I am convinced, is a manifestation of an acute or chronic infection with a streptococcus; particularly is this true of the recurrent form in which the mucous membrane of the mouth is usually involved, and in which acute attacks occur at intervals of from a few weeks to a year or more. In some cases the mucous membranes alone are involved, and the true nature of the attacks is often not appreciated until, perhaps, in one the cutaneous eruption appears.

For example, some years ago I was asked to see a girl who was supposed to be suffering from a syphilitic affection of the vulva and mouth, although the Wassermann reaction was negative. Inquiry revealed the history of former similar outbreaks, sometimes accompanied by a "rash" on the arms. Later she was admitted to hospital under my care for investigation, and very obligingly developed an attack of the oral and vulval lesions and an outbreak of generalised erythema multiforme, following a sore-throat with pyrexia. The tonsils, which were an obvious source of infection, were subsequently enucleated, and an autogenous vaccine from a streptococcus isolated from them was given; some weeks after her discharge she returned with a recurrence of her mucous membrane lesions and a typical eruption of *erythema nodosum* on the shins, which followed shortly after an injection of her vaccine. She ultimately ceased to have her attacks, but was kept under observation for some two years.

A considerable number of these recurrent cases have been investigated by me in association with Eyre, Knott, and Bulleid. In some of these investigation has been very complete, and the patients have been watched over long periods. Our experience may be summarised as follows: (1) There has usually been present some obvious source or portal of entry of infection, usually the nasopharynx and tonsils or the teeth, from which a predominant strain of streptococcus has been isolated. (2) Specific agglutinins to this strain have been found in the patient's serum. (3) Injection of a vaccine of the pathogenic streptococcus has in the majority of cases provoked at first abortive attacks of the erythema multiforme; this, I am aware, is not conclusive evidence of the specificity of the vaccine, but, as a control, other vaccines have been given without this result, and these focal reactions have been a very striking feature in these cases. (4) Of all the therapeutic methods employed—e.g., autohæmotherapy and non-specific protein injections—eradication or local treatment of the main source of infection followed by specific vaccine therapy over a long period has given the best results.

From a study of these cases of recurrent erythema multiforme, and of the conditions apparently due to chronic streptococcal infection, it would appear that the patient becomes infected by, and sensitised to, a strain of streptococcus which to him is specific, and which can often be recovered from various mucous surfaces—mouth, nasopharynx, and intestine. The presence of a "closed" focus of sepsis is by no means necessary; apart altogether from the tonsils, for example, the mucous membrane of the nasopharynx may be a potent source of infection. Apart from the presence in his blood of agglutinins specific for this particular strain, injection of it, even in small doses, may provoke a sharp general and focal reaction, exactly comparable to those induced by tuberculin in a person sensitised to tubercle, whereas he will tolerate quite large doses of other strains recovered from his own mucous membranes or from other patients.

The association of erythema multiforme with acute rheumatic fever, or with rheumatoid arthritis, is, to my mind, beyond question; I have seen it too often, both in my pre-dermatological days and since, to have any doubt on this point. Although the eruption both in its simple and recurrent form is usually not of serious significance, it may be so. Thus, some years ago, a child, at my request, was admitted to hospital for an acute attack of erythema multiforme, with swelling of the joints, following tonsillitis; endocarditis and pericarditis supervened, a streptococcus was obtained on blood culture, and the child died in a few weeks.

Quite recently a girl of 18 years was admitted under my care for erythema multiforme, of characteristic appearance and distribution, except that many of the lesions were purpuric. She had had recurrent attacks of tonsillitis during the previous six months. Shortly after admission another attack developed, accompanied by considerable fever, and with this a scarlatiniform erythema appeared on the face, limbs, and trunk, the erythema multiforme lesions being still present on the backs of the hands. There was an apical systolic bruit with dilatation of the left ventricle. Later an indurated area of cellulitis arose on the back of the neck, which broke down and discharged pus; from this an acute erysipelas spread downwards over the shoulders and back to the buttocks; in the centre of the back a considerable area of skin became gangrenous, and around this large bullæ formed. Pus from the original site of cellulitis gave a mixed growth of *Streptococcus pyogenes longus*, *Staphylococcus aureus*, and *Bacillus xerosis;* from the serous exudate in the lumbar region a pure growth of *S. pyogenes longus* was obtained.

In spite of injections of scarlatinal antistreptococcal serum the patient's condition grew steadily worse, and she died.

Post Mortem.—Soft vegetations were found on the posterior wall of the left ventricle, extending to the edge of the posterior cusp of the mitral valve, and covering the chordæ tendineæ and the apices of the papillary muscles. There was no evidence of previous valvular damage. The other findings

(1) *The Lichenoid Eruption.*

This is a polymorphic eruption consisting of small papules, some plane like those of lichen planus, but the majority follicular, varying in colour from pale yellowish-brown to bright red. The follicular papules may be capped by a horny scale or plug (one form of lichen spinulosus), or by a vesico-pustule. This form is represented, as will be seen in the table, by lichen scrofulosorum, the lichenoid trichophytide or microsporide, and by the lichenoid follicular syphilide.

Type of eruption.	Syphilides.	Tuberculides.	Trichophytides.	Streptococcides.
Papular lichenoid, usually follicular.	Lichenoid follicular syphilide.	Lichen scrofulosorum.	Lichen trichophyticus.	Lichenoid follicular eruption—e.g., in association with streptococcal impetigo.
Eczematoid.	—	Dermatitis scrofulosa (eczema scrofulosorum).	Eczematoid trichophytide.	Eczematoid, or frankly eczematous dermatitis associated with focal streptococcal infection.
Erythema multiforme.	(?)	(?)	Erythema multiforme trichophyticum (Bloch, Rasch).	Most cases of erythema multiforme of the classical and particularly of the recurrent type.
Erythema nodosum.	Doubtful.	Yes.	Yes (Bloch, Sutter, Pulvermacher, Bruusgaard.	Probably the great majority of cases.
Erythema circinatum.	Circinate tertiary syphilide.	Yes. (Darier.)	—	Erythema annulare centrifugum.
Erythema scarlatiniforme.	—	(?)	Yes. (Sutter, Bloch.)	Erythema scarlatiniforme recurrens. Scarlet fever.
Erythema induratum.	Yes. (Ravaut, Tzanck and Pelbois, Pautrier and Darier.)	True Bazin's disease.	—	Non-tubercular form (Whitfield) "Nodosités rheumatismales."
Lupus erythematosus.	(?) according to some authors.	Yes.	—	Yes.

Now Whitfield[29] was, I believe, the first to describe an eruption occurring in association with streptococcal impetigo, usually, but not necessarily secondary to pediculosis capitis. Let me quote his own admirable description :—

> "The first sign to be added to those of the simple impetiginous lesion is the eruption of extremely fine miliary papules, situated at the orifices of the hair follicles of the sides of the back of the neck extending down nearly to the clavicles. These papules appear to be produced by the erection of the hair follicles, and are at first slightly if at all reddened. They may remain in this stage until they subside, or they redden and even become covered with minute vesicles, though this is uncommon. They resemble closely, except as to situation, the papules of lichen scrofulosorum."

It will be seen how nearly the description corresponds to that of the lichenoid tuberculide, syphilide, or trichophytide. I have recently seen a patient with a widespread streptococcal impetigo of the face and neck; on stripping him, there was found on the back and chest an ill-defined erythematous eruption, associated with groups of tiny follicular papules. At his second visit, when his impetigo had almost subsided, all trace of this secondary eruption had disappeared.

(2) *The Eczematoid Eruption.*

There has been considerable discussion as to whether one is justified in describing an eczematoid tuberculide—the eczema scrofulosorum of the older authors. In 1920, Attwater, Marshall and I[30] described a series of cases of an eczematoid dermatitis, occurring almost exclusively in children and adolescents as scaly patches of a characteristic fawn or pale brown colour, usually dry, but sometimes oozing—probably as a result of scratching or rubbing—and situated chiefly on the extensor surfaces of the limbs, the trunk, and on the face, particularly on the temples and forehead below the margin of the hair.

In about 80 per cent. of the cases described Marshall and Attwater were able to demonstrate definite signs of active tuberculosis. I christened the eruption "dermatitis scrofulosa." In 1926, Dowling and I[31] described a further series of these cases, and we showed (1) that exactly similar patches may arise de novo, and persist for some time in tuberculous children at the sites where Pirquet's cuti-test with tuberculin has been done, and (2) that in children with dermatitis scrofulosa patches identical in appearance and histological structure with those already present may be produced by applying tuberculin to the skin. We also observed cases of undoubted lichen scrofulosorum, in which patches of dermatitis scrofulosa were coexistent, and put forward the view that the latter is an eczematoid variety of the former. I am also of the opinion that the so-called "fausse teigne d'Alibert" is merely dermatitis scrofulosa occurring on the scalp.

Some years ago a child whom I had treated in infancy for eczema was brought to me for scaly patches on the limbs and trunk, which were characteristic of dermatitis scrofulosa, accompanied by slight generalised enlargement of the lymphatic glands. The practitioner in charge of the case was entirely sceptical of my opinion that the child had active tuberculosis, but a week later there occurred an outbreak of typical lichen scrofulosorum, and the late Dr. J. J. Perkins confirmed the diagnosis of tuberculous adenitis.

Hügel, Eliascheff, and Schaumann[32] have recorded cases of lichen scrofulosorum in which the normal papular eruption was associated with "brownish red scaly patches of psoriasiform aspect." Schaumann found in microscopical sections infiltration with epithelioid and giant cells around the follicles.

Comparable to dermatitis scrofulosa is, I think, the eczematoid trichophytide described by Jadassohn and Guth, and the eczematoid microsporide by Finnerud.[33] It is generally agreed that they are varieties of the lichenoid trichophytide or microsporide, just as dermatitis scrofulosa may be regarded as a variety of lichen scrofulosorum. I believe that these eczematoid eruptions are due to the sensitisation of the epidermal cells to the toxins—tuberculin and trichophytin respectively—and the artificial production of dermatitis scrofulosa by applying tuberculin to the skin is in favour of this view. The other tuberculides and trichophytides, with the possible exception in some instances of the lichenoid varieties, are, of course, held to result from embolism of the actual organism, dead or living, and not to their toxins.

Can we recognise a comparable eczematoid streptococcide? I think we can with reasonable certainty. Whitfield remarks in his description of the lichenoid eruption associated with streptococcal impetigo of the scalp :—

> "In some cases the secondary eruption is limited to this, but in others there occurs, after a variable number of days, an acute outbreak all over the chest, abdomen, and shoulders of an annular or figurate erythematous eruption with secondary scaling, such as would be classed in the ordinary way as a circinate seborrhœic eczema of the trunk."

This description tallies exactly with the description of eczematoid trichophytide and microsporide given by Guth and Finnerud respectively.

Numerous authors have reported focal reactions after injection of tuberculin, and even acute generalised outbreaks have been thus provoked.

Dyson,[47] rubbed tuberculin and streptococcal ointments into the lesions in a number of cases, and out of 43 patients tested with tuberculin 30, or 68 per cent., gave positive reactions; of eight cases tested with streptococcal ointment 3, or 35 per cent., were positive.

That tuberculosis is, however, not the invariable cause would appear certain from the published post-mortem records of acute fatal cases, in which little or no trace of tuberculosis was found after the most careful search. Schaumann's attempt to reconcile this with his view that the eruption is always tuberculous is too complex to discuss now. The majority of fatal cases published recently have apparently died of streptococcal septicæmia, in some a pure culture of a streptococcus has been obtained from the blood during life, as in those recorded by Sibley[48] and Gibson.[49] Gray suggests this may have been due to a terminal infection, although in one of his own cases, in which a positive blood culture was obtained, the patient recovered.

Without pursuing the discussion further, I would emphasise the clinical similarity between erythema multiforme and lupus erythematosus, which was remarked upon by Galloway and MacLeod[50] many years ago. In the more acute forms of the latter, as I have said, the lesions are indistinguishable from those of the former, and both eruptions involve the mucous membranes of the mouth and conjunctiva. It is of interest, too, that, whereas erythema multiforme is not uncommonly associated with rheumatic fever, lupus erythematosus sometimes accompanies chronic rheumatoid arthritis. The eruption of erythema multiforme, although liable to recur, disappears without leaving any trace, and in rheumatic fever, though recurrence is the rule, the joints recover completely; lupus erythematosus, on the other hand, tends to persist and to produce scarring, just as rheumatoid arthritis is essentially chronic and liable to cause permanent damage to joint structures. One of the worst and most intractable cases of lupus erythematosus I have ever had under my care has mitral and aortic valvular disease dating from childhood, with auricular fibrillation, chronic rheumatoid arthritis chiefly of the finger-joints, and extensive lupus erythematosus of the face neck, and hands. The eruption has remained entirely unaffected by injections of sanocrysin and krysolgan, which are strikingly successful in the majority of those cases of the disease in which tuberculosis is the probable underlying cause.

(6) *Erythema Induratum.*

Under this term are included two types of indolent subcutaneous nodule.

The first type is merely a variety of the so-called hypodermic sarcoid, and is a subcutaneous tuberculide; commonly known in this country as Bazin's disease, it is seen almost exclusively in young girls with the condition of the legs that I described in my first lecture under the term "erythrocyanosis crurum puellaris"—i.e., fat, blue, œdematous legs, in which there is vascular stasis, most evident on the posterior external surfaces of the lowest third. Since the nodules of erythema induratum are of embolic origin, they occur most commonly, as one would expect, on the above area. The nodules may slowly resolve or may rupture and exude an oily fluid, the product of fat necrosis; in the latter case indolent ulcers, which become secondarily infected with pyogenic organisms, result. I believe that all genuine cases of this type are tuberculous; numerous successful animal inoculations with material from the nodules have been made both in this country and abroad; the patients give strongly positive cutaneous and intracutaneous tests with tuberculin, and marked focal reactions if this be injected. Like lichen scrofulosorum nodules may arise for the first time in a tuberculous person after a therapeutic injection of tuberculin. Not uncommonly, papulo-necrotic tuberculides and erythema induratum coexist in the same patient.

The second type was well described by Whitfield[51] many years ago. The lesions, I think, correspond to the "nodosités rheumatismales" of the French. Whitfield says that he has seen it "exclusively in women of from 35—45 years of age, who have suffered from chronic rheumatism supervening on typical acute rheumatism" and he believes "that they are the result of septic absorption, often from the teeth."

I have recently seen a case of this sort in a middle-aged man, who consulted me for an indolent subcutaneous nodule above the right ankle, with considerable brawny œdema around it; later, several fresh smaller nodules appeared on the lower parts of both legs. He was found to have apical infection of several dead teeth, with considerable involvement of alveolar bone. These teeth were extracted, and a vaccine prepared from a streptococcus isolated. The nodules gradually disappeared, but a fresh one appeared after the third dose of vaccine. There has been no further recurrence.

It is possible, as Guy[52] suggests, that other organisms apart from the tubercle bacillus and a streptococcus may produce similar embolic subcutaneous lesions.

PATHOLOGICAL ANATOMY.

A study of the pathological anatomy of these allergic eruptions is of extreme interest, but I can only deal with it very briefly. As might be expected, the changes are for the most part centred round the vessels either of the dermis or hypodermis. A comparison may well be made between the histological picture presented by some of these lesions and that of Aschoff's nodules in the myocardium of cases of acute rheumatism, and of the subcutaneous nodules, both of this disease and of chronic infective arthritis, which, as Carey Coombs[53] emphasises, must also be of embolic orgin.

One may ask upon what depends the differences between these various types of eruption, seeing that some of them can be provoked by widely different organisms; or, for that matter, why does the circulation of the same organism—e.g., the tubercle bacillus—give rise in some cases to a lichenoid eruption, in others to a papulo-necrotic lesion, in others to an erythema induratum or nodosum? I think the chief factor determining the type of lesion is the localisation of the embolised organism or the action of its toxin.

In eruptions such as the roseola of syphilis the organism presumably comes to rest in the superficial capillaries of the skin; in the lichenoid eruptions, the inflammmatory reaction is also superficial, in the papillary body or more particularly around a pilo-sebaceous follicle; in the papulo-necrotic type it is deeper in the dermis. In erythema nodosum and erythema induratum the reaction takes place around a vessel in the subcutaneous tissue. From the observations of Hadfield, recorded in Symes's recent book, made on material supplied by the latter, it appears that the essential lesion in erythema nodosum is "an acute and widespread *arteriolitis* in the subcutaneous fat, resolving rapidly without suppuration." His statements that a recent lesion "showed all the phenomena of acute inflammation, such as follows the actual presence of pyogenic cocci in the subcutaneous tissue," and that "it would have been permissible from an examination of the recent lesion alone to form the opinion that suppuration was likely to occur in it," are of great interest. They suggest that in the cases from which the material was taken were of streptococcal origin. Hadfield failed to find cocci, and he concludes that the lesion is "due to a circulating toxin," but this opinion does not take into account the essential nature of these allergic eruptions—namely, the rapid destruction of embolised organisms.

In erythema induratum Schaumann has adduced evidence to show that the embolism occurs in one of the vasa vasorum of a subcutaneous vein—the lesion being essentially a *phlebitis.*

In both erythema nodosum and erythema induratum there is extensive *fat necrosis*, the products of which are absorbed by histiocytes and giant cells.

FACTORS PREDISPOSING TO THE OCCURRENCE AND LOCALISATION OF THESE ERUPTIONS.

I have already indicated, when discussing the tuberculides and trichophytides, that there are two factors essential for the occurrence of these and similar eruptions—namely, the presence of the causal organism or its toxin (the antigen), and the sensitisation of the tissue cells in the skin or subcutaneous tissue—i.e., the presence in them of antibodies. The various lesions constituting the eruptions are inflammatory reactions resulting from contact of the antigen with the antibodies of the specifically sensitised cells. This phenomenon constitutes "allergy" in the sense originally employed by Pirquet; of late, however, the term has been given a wider significance, as I shall point out in my next lecture, although its essential meaning remains the same.

As Bloch[54] says: "It is clear that an organism which possesses or has acquired (by previous contact) such specific antibodies, will react to the application of the specific antigen differently from an organism which does not possess such antibodies (allergy = different reaction)." Bloch also makes the following deduction, which to my mind is of fundamental importance, both with regard to the eruptions we have been considering and to allergic reactions in general: "The type and course of the allergic reaction are independent of the nature of the antigen, but vary according to the localisation of the antibody—that is, according to which organ reacts to the antigen."

Now until recently it has been held that in true anaphylaxis and allergy the antigen must be a protein, but this view is no longer tenable; it is, in fact, highly probable that the actual specific antigenic bodies, no matter what their source, are non-protein substances of relatively simple chemical composition. This question I shall refer to also in my next lecture. For our present purpose, if this be accepted, it is clear that it is of no consequence whether the various eruptions—tuberculides, trichophytides or streptococcides—are produced by the actual causal organisms, or by their toxins, circulating in the blood stream, and reaching the sensitised tissue of the skin or subcutaneous tissue, since the antigenic substance is presumably present in both. Given, however, the *essential* factors for the production of these eruptions—namely, sensitisation of the cutaneous or subcutaneous tissues, and the access to them *via* the blood stream of the specific antigen—there are, nevertheless, certain other factors predisposing to their occurrence and distribution. Of these I think the most important are: (1) circulatory stasis in the skin and subcutaneous tissue of certain areas; and (2) the action of physical agents such as light, heat, and cold.

This question has been dealt with by Adamson,[55] both in his Goulstonian Lectures and in a more recent communication, and by Lewis[56] in his work on the blood-vessels of the human skin.

It is obvious that, in the case of eruptions dependent upon circulatory micro-organisms or their toxins, stasis in the blood-vessels of a given area will predispose to the embolism of the former or the more prolonged noxious action of the latter. This influence of circulatory stasis is clearly seen in erythema induratum, in the papulo-necrotic tuberculides, in lupus erythematosus, and to a less extent in erythema multiforme and nodosum. Moreover, Adamson has suggested that the roseolar and papular eruptions of secondary syphilis arise at the angles of the vascular network, demonstrated many years ago by Renault—i.e., at the sites of maximum capillary stasis. This network is revealed in certain subjects by exposure of the skin to cold (livedo annularis), or to prolonged heat (erythema or ephelis ab igne), both of which agents increase the stasis in the vessels of low tone farthest away from the central arteriole. Lewis has shown that these vessels are irresponsive to adrenalin and refractory to histamine.

The second factor—namely, the action of light in determining outbreaks and the localisation of certain of these eruptions, is illustrated by some cases of erythema multiforme and lupus erythematosus.

One of my patients with recurrent erythema multiforme, who formerly had frequent attacks, now has one annual attack, which invariably occurs when she first exposes herself to strong sunlight in spring or early summer.

Another, a little girl, whose erythema multiforme began after scarlet fever, was always free in winter, but developed fresh lesions every time she was exposed to sunlight. She was comparatively free last summer, after enucleation of septic tonsils and subsequent vaccine treatment. In her case there was little doubt that her skin became sensitised to a *Streptococcus longus* at the time of her scarlet fever. This provoking action of sunlight is also seen in some cases of lupus erythematosus.

SIGNIFICANCE AND VALUE OF THE CUTANEOUS AND INTRACUTANEOUS TESTS.

When we survey the problem of rheumatic fever and rheumatoid arthritis on the one hand, and of some of the eruptions with which I have just dealt—such as erythema multiforme, erythema nodosum, and lupus erythematosus—on the other, we are struck by one very significant fact—namely, that the chief point of controversy concerning their ætiology centres round the streptococcal group of organisms. Personally, I am satisfied that erythema multiforme of the classical type and erythema nodosum are, in the majority of cases, streptococcides, and that the latter, at any rate, may less commonly be a tuberculide; with regard to lupus erythematosus, I think the evidence that it is sometimes of tuberculous origin is conclusive, and, since in 1915 I first put forward the view of its streptococcal origin in certain cases, confirmatory evidence has accumulated in favour of my claim. I believe that it is often possible clinically to distinguish between the tuberculous and the streptococcal form from the appearance of the eruption.

I have already referred to the difficulty of establishing beyond question the streptococcal origin of a given eruption, or, for that matter, of general diseases such as rheumatic fever or rheumatoid arthritis. I think, however, that valuable evidence might be obtained by carefully controlled intracutaneous tests with emulsions or preferably filtrates of streptococci, such as have been employed by Birkhaug,[57] Strauss,[58] Kaiser,[59] Swift and his co-workers, in their researches on rheumatic fever. This leads me, however, to a consideration of the whole question of diagnostic cutaneous tests with tuberculin, trichophytin, and similar extracts.

With regard to the tuberculin test, I agree with Burhans[60] and Lyle Cummins[61] that the intradermal method of Mendel[62] and Mantoux[63] is preferable to the cutaneous test of Pirquet. I believe that the significance of these tests is widely misunderstood, and it is for this reason that by many they are regarded as comparatively useless. To my mind they afford evidence of one thing and one thing only—namely, that the skin is sensitised to the specific antigenic substance of the infective organism in question. It follows that a positive reaction indicates that an infection with the particular organism has taken place and that there is cutaneous allergy towards it; a negative one excludes the latter, but *not* the former. Lyle Cummins says: "Tuberculin sensitivity is at its height in healthy but infected adults, and is still high in those tuberculous persons in whom the disease is taking a relatively benign course, and it tends to diminish with the gradual deterioration of health consequent on advancing tuberculosis." This statement is true, but it does not emphasise the real meaning of his observations. Since a positive cutaneous or intracutaneous reaction is an index of the degree of cutaneous allergy, it follows that the higher the latter the stronger the reaction. As one would expect, therefore, it is in patients with tuberculide eruptions, which depend for their occurrence on an allergic state of the skin, that some of the strongest reactions are obtained.

As I shall point out later, cutaneous allergy is a protective mechanism against more serious visceral involvement; it disappears for a while after acute infections such as measles, during which time also the Pirquet and intradermal tests become negative; and in advanced cases of tuberculosis, when the protective function of the skin has failed, these tests diminish in intensity.

Colliver[44] has shown that in tuberculosis the Pirquet test, if positive, gives the same degree of reaction in different areas, but this is not so in trichophytosis, in which, of course, the primary site of infection is always in the skin itself. This is shown by the experiments of Pedersen[45] and of Sutter[46] with trichophytin.

Pedersen tested nine cases of suppurating ringworm without secondary trichophytides, with trichophytin by Pirquet's method. All gave positive reactions on the abdomen, seven were positive on the arm, and only four on the leg. The abdomen is one of the chief sites of election for the trichophytide eruptions. Pedersen also tested six cases in which secondary trichophytides were present. All were positive on the abdomen and upper arm where the trichophytides were situated, and only two on the leg where there were no trichophytides. He and Sutter both showed that the cutaneous reaction was always strongest near the site of the suppurating ringworm infection.

From their analogy to the tuberculides and trichophytides the eruptions that I have termed streptococcides should be accompanied by a similar cutaneous allergy towards streptococcal antigen, and positive cutaneous or intracutaneous tests should be obtained with it. An obvious difficulty, however, is the question whether the actual antigenic substance is common to the streptococcal group as a whole, or whether different strains have their own specific substance.

I have already referred to the tests carried out by several workers with emulsions or filtrates of streptococci in rheumatic patients. Recently Forman, in my clinic, has made intradermal tests with streptococcal emulsions, using staphylococcal emulsions and normal saline as controls, in patients with eruptions that I consider to be streptococcides, in apparently normal subjects, and in patients with other diseases. So far as our observations go, this line of research has given significant and promising results.

THE RÔLE OF THE SKIN IN THE DEFENSIVE MECHANISM OF THE BODY.

I have already referred to the importance of impaired function of the skin as a predisposing factor to the development of rheumatic conditions, and in my first lecture I emphasised the relationship between the skin and the activity of the endocrine glands, particularly the adrenals and thyroid, and of the autonomic nervous system, upon which the resistance of the tissues to certain bacterial infections, as Cramer's work suggests, appears largely to depend.

Llewellyn, Gordon, and Gunzberg, in their remarks at the Bath Conference, all laid stress on the symptoms of disordered cutaneous circulation and sweat secretion that are so apparent in rheumatic subjects, and Langdon Brown, Thomson, Pringle, and Strauss dealt with the endocrine factors.

I think it will be generally admitted that, apart from removal and treatment of definite sources of infection, and the employment of vaccines in suitable cases, the methods of treatment in chronic rheumatic conditions which have proved of most value depend very largely, as Howitt[47] has recently emphasised, on stimulation of the skin, whether by increasing the secretion of sweat, or by flushing the cutaneous blood-vessels, or by producing in it a definitely inflammatory reaction, as with erythema doses of ultra-violet light, or the deliberate application of irritant substances. By these various methods one can utilise the excretory function of the skin, increase tissue oxidation, stimulate the adrenal-thyroid-sympathetic system, as by alternate hot and cold douches, and lastly produce what is apparently mild protein shock, which, after a preliminary leucopenia, leads to a considerable leucocytosis and an increase in the bactericidal power of the blood. It is my contention that susceptibility to active infection with the less virulent types of streptococci, as well as with some other organisms, such as the tubercle bacillus, is dependent largely on the prevention of the normal physiological functions *of the skin by the unnatural conditions imposed by* civilisation, and that by far the most effective treatment for such infection, when it has occurred, is the restoration of those functions by all the means at our disposal.

Apart from this, however, in conclusion I would raise a question that to my mind is of profound interest and importance—namely, that, when active infection is present, to what extent do the cutaneous manifestations of such infection constitute a protective mechanism against invasion of deeper and more important organs? May not the rashes of the acute exanthemata, and of the more chronic infections such as syphilis and tubercle, represent part, at any rate, of the body's campaign against the invading organism, since, as we know, they represent antigen-antibody reactions designed to destroy the former in situ? May not, in fact, recovery from an acute exanthem be partly dependent on the rash?

The evidence in favour of this view is very strong. The popular conception of most skin eruptions is that they represent an effort to drive out some poison from within, and anxiety is often expressed about the danger of driving it in again! We should not be too ready to dismiss this idea as an ignorant superstition. Brocq[48] has long upheld the view—earning for himself much scorn in so doing—not only that certain eruptions alternate with various visceral and nervous disorders, which is an indisputable fact, but that the successful treatment of the former may precipitate an attack of the latter, which in turn may be promptly relieved by exciting an inflammatory reaction in the skin. On this idea depend the older methods of treatment by blistering, setons, cupping, scarifications, and the like. We now attempt to treat the underlying infection or toxæmia, on which both the cutaneous and visceral symptoms depend.

In tuberculosis it has long been recognised that patients who suffer from tuberculides and lupus vulgaris are comparatively immune to the more deadly forms of this disease, such as actively progressive phthisis. According to Burnet,[49] it is probable that the skin of all the tissues is that which lends itself best to the spontaneous attenuation of the tuberculous virus. "It is not a matter of indifference," he says, "for a tubercular person that his skin be affected before his lung, or his lung before his skin, and his phthisis is without doubt not the same as if his skin were not involved." Moreover, we know that should the severer forms of visceral involvement, or a general miliary tuberculosis supervene in a patient with tuberculides or lupus, the skin lesions automatically disappear, and the Pirquet reaction—the index of cutaneous allergy—often vanishes with them.

In syphilis it is common knowledge how seldom tabes and general paralysis occur in those who have had severe cutaneous manifestations. Years ago when I was investigating the histories of large numbers of tabetics, I was struck by the fact that few of them retained any recollection of a syphilitic eruption. Moreover, the recent publication by Bruusgaard[50] must give us pause. His predecessor, Boeck, always taught that mercury and iodide were symptomatic remedies, which not only fail to cure the disease, but actually paralyse the body's natural defences, so that when they are administered the infection runs an atypical course, and is much more liable seriously to damage internal organs, particularly the central nervous system. This, of course, was in the pre-salvarsan days. Boeck only employed these drugs in cases in which the disease failed to run its natural course. Bruusgaard and Dählstrom in an exhaustive analysis of Boeck's old patients (some of whom, no doubt, did receive mercury and iodide from other doctors), found that only 0.0 per cent. developed general paralysis, as compared with the usual computation of 4 per cent.

In ringworm (trichophytosis) we know from Bloch's experiments that immunity to reinfection is a function of the allergic condition of the skin cells. In human favus the cuti-reaction is almost always negative, showing that to this fungus (*Achorion schönleinii*) the skin fails to develop antibodies; this fact may well explain why human favus is a chronic disease without any tendency to spontaneous cure.

Lastly, when we come to the eruptions that in my opinion may legitimately be termed rheumatic, or at any rate streptococcides, cannot we detect the same protective rôle against visceral damage? Those, who like Gosse,[71] Lendon, and Symes, base their opinion that erythema nodosum is not a rheumatic disease on the fact that it is comparatively seldom associated with permanent damage to the heart or with chorea, and that it infrequently recurs, have, I believe, failed to grasp the whole story of rheumatic infection, and to understand the significance of its cutaneous manifestations. One might equally well argue that gummata are not syphilitic because they so seldom occur in tabetics and paralytics, or vice versa. That erythema nodosum *is* sometimes associated with typical rheumatic fever and its cardiac complications is certain. That the association is not more frequent is, I submit, because as with the tuberculides and syphilides, the allergic state of the skin on which it depends protects the more vital organs. The same may be said of erythema multiforme.

CONCLUSIONS.

(1) My conclusions are that one may justifiably compare tuberculosis, syphilis, and rheumatism.

(2) That there is increasing evidence that rheumatic fever and some of the chronic forms of rheumatic disease are due to streptococcal infection.

(3) That certain cutaneous manifestations of these three infections and of the severer forms of ringworm are comparable and sometimes indistinguishable; and that they depend on an allergic condition of the skin.

(4) That this allergic condition of the skin is to some extent a protective mechanism against involvement of more vital organs.

(5) That interference with the normal physiological functions of the skin, such as is bound to occur in the majority of persons living under civilised conditions, is an important factor in predisposing to active infection with certain organisms, such as the tubercle bacillus, and with the common saprophytes of the mucous membranes and skin.

FURTHER OBSERVATIONS ON THE HISTOLOGY OF CARCINOMA OF THE BREAST.

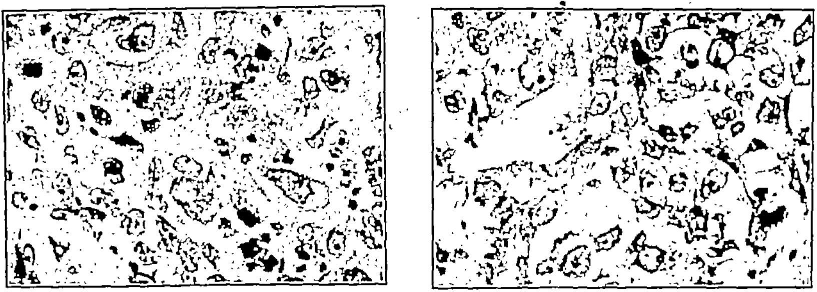
BY D. H. PATEY, M.S. LOND., F.R.C.S. ENG.,
ASSISTANT SURGEON TO THE HAMPSTEAD GENERAL HOSPITAL;
AND
R. W. SCARFF, M.R.C.S. ENG.,
ASSISTANT PATHOLOGIST TO THE MIDDLESEX HOSPITAL.

(From the Bland-Sutton Institute of Pathology, Middlesex Hospital.)

WITHIN recent years many investigations have been conducted with the object of ascertaining the relationship, if any, which exists between the varied histological pictures presented by carcinomata of similar organs and their response to treatment, either surgical or radiological. As a result, certain workers (e.g., Broders, Healy, Greenhough), have concluded that an index of malignancy based on the histological features should prove of value clinically. As a rule it has been found that attention is best directed to the actual tumour cells, neglecting or paying small attention to stromal changes.

In a previous communication [1] we brought forward evidence to show that in the case of carcinoma of the breast such a relationship between the histological appearance and the subsequent clinical course of the disease does exist; but we came to the conclusion that the histological index of malignancy should be used only as an auxiliary to other factors, and that the important point was the stage to which the disease had advanced at the time the treatment was undertaken. In actual practice it was believed that the histological malignancy should prove of prognostic value in cases in which the disease had spread from the breast to the axillary glands, but had not yet widely infiltrated those glands—i.e., a group intermediate between the early and the advanced cases of carcinoma of the breast. In furtherance of this work, we thought it might be of interest to study the relationship between the histological appearance of the primary growth and that of its secondary deposits. The results of such an investigation are herewith recorded (A). In addition, under (B) the histology of those tumours of the breast which have given rise to metastases in the glands is compared with the appearances of those growths in which microscopical examination of the axillary glands has failed to demonstrate metastases.

FIG. 1.

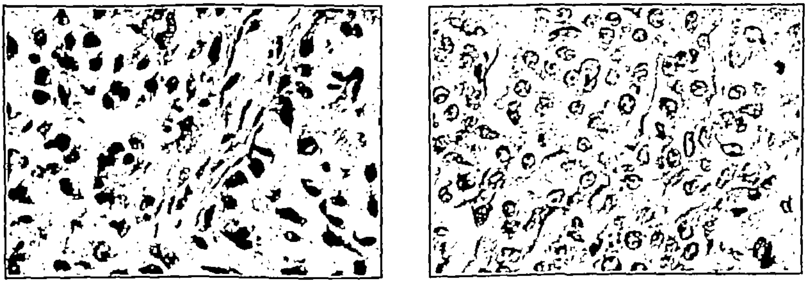


A.—Primary tumour.

B.—Secondary deposit in axillary gland.

The tumours are identical in appearance and malignancy.
(The majority of the cases were in this category.)

FIG. 2.



A.—Primary tumour (Group 3).

B.—Secondary deposit (Group 2).

The secondary deposit is less malignant than the primary growth.

(A.) *The Relationship between the Histological Appearances of the Primary Growth and its Secondary Deposits.*

In spite of its apparent importance no detailed accounts of the comparative histology of primary carcinomata and their secondary deposits have been traced, although generalisations on the subject are not infrequent. Ewing,[2] discussing carcinomata in general, states that "in metastatic deposits preservation of structural type is often remarkable yet, as a rule, there is increased anaplasia and more rapid growth in metastatic tumours." Delbet and Mendaro,[3] on the other hand, speaking of breast carcinomata, say that the secondary deposits in lymphatic glands are often more differentiated than the primary tumours. In neither case are examples quoted, nor is any detailed analysis given.

The material examined consisted of the microscopic sections of 110 consecutive cases of carcinoma of the breast submitted to the operation of radical removal at the Middlesex Hospital, from 1926 to 1928 inclusive, in which histological examination showed metastasis in the axillary lymph nodes. The method of study of the cases was identical with that used previously, and the material was classified into three groups, Group I. representing a low and Group III a high degree of malignancy.

The criteria adopted in assessing the malignancy have already been given,[1] and briefly are those changes which indicate the degree of departure from the structure and arrangement of normal breast epithelium. The three characters on which most stress has been laid are: (1) tubule formation; (2) irregularity in size and shape of nuclei; (3) hyperchromatism. Other factors which have been noted are: (4) the amount of secretion and (5) the number of mitoses.

No attention has been paid to the presence of fibrosis, leucocytic infiltration, nor any factor not directly concerned with the appearance of the epithelial cells.

In order to obtain an opinion as unbiased as possible the sections of all the primary tumours were first examined, and then independently the sections of the secondary deposits. Each primary growth was then compared with its metastases, and any differences noted on the independent examination were discussed and, if necessary, confirmed.

The results of the analysis are summarised in Table I.

TABLE I.—*Showing Numbers of Cases with and without Changes in Malignancy of Metastases.*

Histological group of primary.	No. of cases.	Metastases in same group.	Metastases in lower group.	Metastases in higher group.
1. Low malignancy	24	24	—	0
2. Moderate ,,	39	28	10	1
3. High ,,	47	39	8	—
Total	110	91	18	1

It will be seen that, of the 110 cases studied, in 91 the breast and glands were classified as being similar in histological type and malignancy; of the remaining 19, in 18 the secondary deposits were placed in a lower category than their corresponding primaries, whilst in only one instance was it found that the glandular deposits had been placed in a higher category. As a result of these findings one may say that in the large majority of cases of carcinoma of the breast (approximately 83 per cent. in this series) the histological malignancy of the secondary deposits in the axillary glands is almost identical with that of the primary tumour; in an appreciable minority (16 per cent.) the secondary deposits have a less malignant appearance, whilst only rarely (one case) does the growth in the glands appear more malignant than the primary tumour.

Discussion.—With regard to the practical application of this investigation two points of importance suggest themselves. In the first place it is seen that in assessing the malignancy of carcinoma by histological means attention should be directed to examination of the primary growth. Furthermore, it is obvious that it would be useless to look for signs of prognostic value in the primary growth if, in many cases, the metastases were of a higher malignancy, as each secondary growth would serve as a focus for the spread of carcinoma more malignant than the original primary tumour. But the investigation has shown that in the breast, at any rate, this occurs so rarely as to be negligible.

The other point upon which this investigation has some bearing is that of radium treatment. It is well recognised that, in many situations, the radium treatment of lymphatic secondary deposits is less successful than that of the primary growth. The question arises whether this is due solely to difficulties of access or whether other factors, such as alteration in the radiosensitivity of the growth cells, are concerned. Regaud,[4] Healy,[5] and other workers maintain that the more differentiated a tumour the less is its response to radium. If this hypothesis be correct, since in the breast the large majority of the glandular secondary deposits have a similar appearance to that of the primary growth, they should react in the same way to radium; but in the occasional case in which the growth in the gland is more differentiated this secondary growth might prove more refractory to radium.

(*B.*) *Histological Malignancy and Metastasis.*

During the period in which the above 110 cases of carcinoma of the breast with axillary secondary deposits were encountered there were 53 cases which showed no secondary deposits. These 53 cases constitute 32·5 per cent. of the total number which underwent the radical operation, a figure which agrees closely with that of 30 per cent. quoted by Barling for the cases in the Birmingham Hospitals.[6] They also were examined and classified in the manner noted above, and the reults are given in Table II.

TABLE II.—*Histological Malignancy and Metastasis.*

Histological group of primary.	Total No. of cases.	No. with metastases (from Table I.).	No. without metastases.
1. Low malignancy ..	54	24	30
2. Moderate ,, ..	57	39	18
3. Marked ,, ..	52	47	5
Total	163	110	53

It will be seen that more than half (56·6 per cent.) of the cases which have not metastasised are of low histological malignancy, whilst only about one-tenth (9·4 per cent.) are in the high category. When these results are compared with those of the tumours which have shown secondary deposits a striking difference is noted, as of the latter only 22 per cent. are in the low grade, whereas 43 per cent. of the tumours are of high malignancy.

These results, in addition to verifying the relationship between histological appearance and clinical malignancy, support the conclusion previously expressed that in a carcinoma of the breast of low histological malignancy the early or favourable stage is of longer duration and that patients are more likely to present themselves for treatment before there has been much spread of the disease.

Summary.

(1) 110 carcinomata of the breast with their secondary deposits in the axillary glands, and 53 cases without secondary deposits have been examined from the point of view of the histological appearances of malignancy. (2) In the large majority of instances (83 per cent.) the secondary deposits in the lymphatic glands are similar in appearance and malignancy to the primary growth; in an appreciable minority (16 per cent.) the malignancy of the glandular metastases is lowered, but only in one case is the malignancy raised. (3) The series of cases in which secondary deposits have not been found in the axillary glands shows a relatively much greater number of tumours of low histological malignancy than does the series with such deposits.

THE OCCUPATIONAL DISEASES OF HOP-PICKING.

BY BEATRICE M. SMITHIES, M.R.C.S. ENG., D.P.H.,

SOMETIME RESIDENT MEDICAL OFFICER, HOP PICKERS' HOSPITAL, MARDEN, KENT.

THERE are three recognised affections due to hop-picking, and seen only among hop pickers. These are known as "hop rash," "hop eye" and "hop gout," and are familiar to those who have worked in and among hop gardens. The literature concerning them is, however, scanty.

Hop Rash.

The first mention of hop rash was made by Badham[1] in 1834, who contracted a dermatitis as the result of putting his own chapped hands into a "bin" of hops. He also records the case of a girl of 14 years of age who, while suffering from chilblains, plunged her hands into a "bin" of hops to warm them and then developed a rash similar to the one he had suffered from himself. O'Donovan,[2] in 1924, again drew attention to the condition, and recorded two cases which he saw at the London Hospital. He points out that they follow the general type reaction as described by Sequeira in cases of dermatitis caused by plants. He states that "females only, so far, have been affected from the ages of 12 up to 67, *and always in the month of* September." Lewith[3] notes the occurrence of three cases, all females.

In a letter to THE LANCET in October, 1924, after reading O'Donovan's article, Streich[4] describes a case of hop rash in a woman of 40 who, in addition to the rash on her hands and face, which was typical in appearance, also developed a purpuric rash on her legs. A further reference to the condition was made about the same time by Galbraith,[5] who says that "Dr. Ebden, in charge of the Hop Pickers' Hospital and Dispensaries at Marden, noted 58 cases of hop rash." Galbraith also states his belief that this hop rash, together with the conjunctivitis and synovitis noted, is produced by some irritant from the hop plant. In support of this belief he says that "owing to the remarkable absence of vermin from the hops in the present year (i.e. 1924), no washes have been used." This discountenances any theory there may be that *the affections under consideration are due to the* chemical washes used on the plants. This is *further supported by the fact that* no regular garden employee applying washes to the hops during their period of growth has been known to suffer from the rash, conjunctivitis, or gout.

The next reference to the subject is found in a brief note in the Annual Report for Kent for 1926, as reported in THE LANCET,[6] in which of 25,000 pickers it is said that 237 suffered from hop rash, 95 from hop eye, and 87 from hop gout. It is thus evident that the affections are fairly common among the pickers.

My own attention was first drawn to the subject when acting as medical officer to the Hop Pickers' Hospital and Dispensaries at Marden in 1927, when a number of cases were seen and treated. In 1928, *when acting in the same capacity, I made careful* notes of all cases seen throughout the hop-picking season of August and September, and out of a total of 1172 cases of all kinds 52 were of hop dermatitis. Of these, 4 were men, 39 were women, and 9 were children of both sexes under 14 years of age. The incidence of cases among males is of interest in face of *the fact that all recorded cases have hitherto been* females.

The 52 cases mentioned made a total of 81 attendances at the hospital for treatment, thus indicating the short duration of the disease. It appears to recur in the same individual year after year. One or two adults remembered suffering from it as children and had thereby been deterred from hopping, but they had ventured again thinking that they might have *outgrown their susceptibility. This was not so. One* boy of 12 years of age had suffered from it severely on each of his two visits to the hop gardens, and was not anxious to return the following year, in spite of the alluring prospect camp life in the country must offer to the East-end child.

The onset of the disease is marked by a papular erythema occurring on exposed surfaces; hands, arms, face, in one or all of these situations. The accompany*ing irritation is intense, and it is usually this which* drives the patient to seek medical advice. Concomitant with this is usually some general constitutional disturbance which may be severe. In the worst cases the patient complains of headache and irresistible drowsiness. One case which came to the hospital almost fell asleep as she described her symptoms, and it was only by making a considerable effort that she was able to concentrate sufficiently on her tale to make herself clear. In this case *headache* was a prominent feature. The face and hands were covered with a dense papular erythema, and there was considerable œdema of the parts, so much so that the woman could scarcely see out of her eyes, and was unable to clench her fists.

The papular stage may rapidly become vesicular and then pustular, the pustules varying in size from about one-tenth of an inch to half an inch in diameter. Associated with the dermatitis are invariably a number of small scratches from the hop bines. Pickers' hands are always deeply stained a dark green colour, and have the characteristic smell *of hops about them. The colour is no doubt due to a* conglomeration of hop washes, hop juices, and hop pollen. The presence of innumerable scratches, together with an inevitable inoculation of them with hop juices and pollen, suggests some kind of protein sensitisation.

Hop Eye.

Hop eye has received much less attention than hop rash. It was first discussed by Adams,[7] who made an exhaustive examination of the hop plant, and came to the conclusion that hop eye is due to a mechanical irritation of the eye by the spine-shaped hairs found *on the top bracts, leaves, and bines. The condition is* also recognised by Prosser White,[8] and is mentioned by Galbraith,[5] and the Kent Annual Report, 1926.[6]

At the Marden Hop Pickers' Hospital in the 1928 season, 14 cases of hop eye occurred among the total of 1172 patients treated. Of these, 11 were women and 3 were children. No cases were noted *among men. The condition in a previously healthy* eye is a conjunctivitis. There is considerable lacrymation, and usually there is œdema of the eyelids associated with it. Hop eye comes on rapidly after the eye or eyes have been rubbed with fingers dirty from hop-picking. The patient comes complaining of pain in the eye, smarting in character, which *rapidly becomes worse. On examination the* conjunctiva is uniformly reddened and lacrymation is marked. The amount of accompanying œdema of the lids varies considerably. In one case a woman came running in from the hop garden with a "swollen eye." She was positive that the swelling came up within a few moments of having rubbed the eye with *her fingers.* Her fingers were covered with the usual dark green stain from the hops. The conjunctiva of the eye was *perfectly clear and there was no lacry*mation. The lids were both swollen so much that the patient was unable to open them herself.

As in hop dermatitis, the association between a receptive body surface and a possible source of protein irritation is striking. The similarity between these conditions and those produced experimentally *on a much smaller scale by the cutaneous and ophthal*mic reactions used in the estimation of individual susceptibility to such proteins as those, *for example*, which are known to produce hay-fever, is arresting and merits further investigation.

Hop Gout.

The only references to hop gout are made by Prosser White[8] and Galbraith.[5] It is recognised by *hop pickers and growers as a condition peculiar to the* hop-picking season. Like the dermatitis and conjunctivitis it is never seen at other times of the year among workers in the hop gardens.

At the Marden Hospital in the 1928 season, of the 1172 cases seen only 17 were treated for hop gout. Although 50 per cent. of all cases were children, not *one of them* was found to be suffering from hop gout. Women appeared to be more frequently affected than men, *for of the above 17 cases* 11 were women varying from 20 to 70 years of age, and the remaining 6 were men of from 20 to 58 *years of age. It should* be pointed out that in all three of these conditions the prevalence among women is probably due in part, if not entirely, to the fact that the number of women employed is very much greater than the number of men. The patient suffering from hop gout comes complaining of pain, limitation of movement, and *swelling of fairly rapid onset. It may occur in the* fingers, hand, wrist, or forearm, and is unilateral. The *swelling is red and tense, and on palpation a typical* fine crepitation is felt like the crunching of crisp snow. In most cases the condition runs as short a course as the allied rash and conjunctivitis.

The following are notes of a typical case :—

A man of 20 years came complaining that he could not use the first and second fingers of his right hand, and of a painful swelling on the back of the hand. He had started work on the previous day feeling quite fit as usual. In the afternoon he had noticed that the first finger was "getting tired," It then began to feel numb, so that he had to stop picking and rub it till sensation was restored. After the tea interval the back of the hand had begun to ache, but no swelling was noticeable. He rubbed some liniment into the hand that night and slept soundly. The next morning he found, while dressing, that he could not pick things up easily, and kept dropping them. The back of the hand then appeared to be red and a little swollen. He tried to work in the hop garden that morning, but found that he could only use the hand for short spells at a time. After half an hour's picking a quarter of an hour's rest was necessary to restore the feeling in the hand.

On examination a red tense swelling was seen on the dorsum of the right hand. On palpation it appeared to be very tender. No fluctuation was felt and there was no pitting on pressure. On passive movement of the first finger fine crepitations could readily be felt in the swelling especially along the line of the first metacarpal bone, and similarly on passive movement of the second finger crepitations were felt along the proximal third of the corresponding metacarpal bone. None was felt on movement of the third and fourth fingers. Measurements were made of the swollen parts and comparison made with the sound hand. The patient was not subject to any digestive disturbances, and no trace of a gouty diathesis was apparent.

Whether one is justified in associating this synovitis with the dermatitis and conjunctivitis described remains to be seen. The ætiology of all three of them is as yet obscure, and it is to be proved whether the origin of one or all of them can justly be attributed to a protein sensitisation.

Clinical and Laboratory Notes.

SPONTANEOUS REDUCTION IN VOLVULUS OF THE BOWEL.

BY LIEUT.-COLONEL R. C. MCWATTERS,
M.B. LOND., F.R.C.S. ENG.,
PRINCIPAL, MEDICAL SCHOOL, AGRA, INDIA.

IT is generally believed that volvulus is sometimes reduced spontaneously, but direct evidence is difficult to obtain. for once reduction has occurred there is usually no occasion for either operation or postmortem examination. The following cases are of interest, in that they provide evidence of reduction having occurred.

CASE 1.—A Mohammedan agricultural labourer, aged 50, was admitted to the King George V. Hospital, Lucknow, with a much distended abdomen, occasional vomiting, and periodic attacks of griping pain. He said that in the last four years he had had three similar attacks which had passed off after a day or two. This attack was more severe, and had lasted four days, during which he had passed neither fæces nor flatus. Enemata produced no result, and at operation a volvulus of the sigmoid was found. The affected loop was enormously distended, and its walls were hypertrophied. It was easily untwisted and at once emptied into the rectum. It was then noted that besides a few soft recent adhesions there were old firm adhesions at the pedicle of the volvulus binding the two ends of the loop together, and a patch of old scarring on the bowel, evidently the result of a previous attack. The ends of the loop were separated so far as possible, and fixed, in the hope of preventing a recurrence. The patient recovered.

The next two cases concern the small intestine, and it is necessary here to refer to the frequency of volvulus of the small intestine in India. I have met with it in 6 out of 25 operations, and in 2 out of 4 postmortems.

CASE 2.—A Hindu male, aged about 40, was admitted to the Thomason Hospital, Agra, on the third day of obstruction. He gave a history of a similar attack about two years previously. The general condition was grave.

At operation the cæcum and lower ileum were empty, and on tracing the empty bowel upwards it was found that a few inches above the ileocæcal valve it was firmly adherent to the root of the mesentery. Above this point were some feet of normal but empty bowel. The bowel was then again adherent to the root of the mesentery; from this point upwards it was distended.

The arrangement of the bowel and mesentery was exactly like that of a volvulus; the mesentery was *gathered up like a pedicle between the points of* adhesion to the bowel. But the intervening loop was empty instead of distended, as in volvulus, no twist was really present, and further examination showed that the obstruction was due to a stricture, the result of extensive scarring of the bowel. Obviously there had once been a volvulus which had undergone spontaneous reduction after causing grave damage to the intestine.

The third case is an example of a type very common in India, in which what appears to be grave obstruction is relieved by a succession of enemata, leaving the surgeon wondering what was the nature of the obstruction. But this patient died soon after the relief of the obstruction, and furnished a most interesting postmortem.

CASE 3.—A Nepalese road labourer, aged about 30, was admitted to the Crossthwaite Hospital, Nainital, with distension, vomiting, and pain. The onset, 12 hours previously, had been sudden, and the patient showed some degree of collapse. He had already taken a purgative. He refused operation, and two enemata failed to relieve him. An hour later, after a third enema, he passed a copious watery motion, but became so collapsed that an intravenous infusion was called for. Twenty minutes later a further action occurred and all distension disappeared, but he died a few minutes later.

A post-mortem examination was made within two hours. The only abnormalities found were the following. There were subserous hæmorrhages in the ileum, most marked at the antimesenteric border, and increasing in intensity as the bowel was traced downwards to a point about 4 inches from the ileocæcal valve, where they ceased abruptly. There was also a contusion on the left face of the mesentery at this level, in the form of an oblique streak near its root. There was no thrombosis in the mesenteric vessels. The lower limit of the subperitoneal hæmorrhages corresponded with the usual lower limit of a volvulus of the small intestine, and I have noted identical bruising in one post-mortem and in one operation in cases of volvulus, the bruise being simply the impress of the tense lower end of the loop.

It is impossible to explain these findings, except on the basis of a volvulus which had undergone spontaneous reduction.

EPIDEMIC (LETHARGIC) ENCEPHALITIS

IN A VERY YOUNG INFANT.

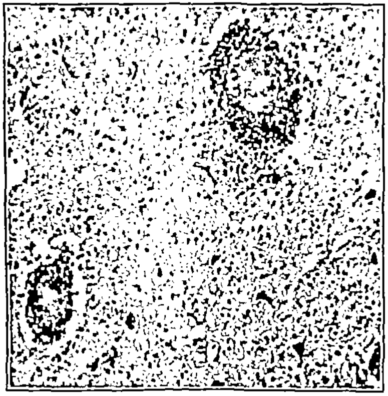
BY ALAN MONCRIEFF, M.D., M.R.C.P. LOND.,
MEDICAL REGISTRAR AND PATHOLOGIST, THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET.

CASES of encephalitis lethargica in very young infants are of rare occurrence, although instances of infected mothers passing on the disease to their offspring have been recorded. The youngest of this type contracted the disease when two weeks old, as described by W. Harris[1] and subsequently further discussed in the Ministry of Health report.[2] Sporadic cases of the disease in early infancy have been described. Neal[3] in a collection of 274 instances of the disease finding four under the age of three months. Happ and Mason[4] recorded a case of encephalitis lethargica in a black baby at the age of five weeks, and Findlay and Shiskin[5] described a non-fatal case of an infant which became drowsy at three weeks of age, with a left internal squint. The following case is put on record because of its exceptional nature, in that symptoms appeared at the end of the second week of life, although there is no evidence that the mother was the source of infection.

A. B. was the first child, born at full term of healthy parents. The mother was in excellent health throughout pregnancy, and neither then nor at any other time had suffered from any symptoms which could be attributed to encephalitis lethargica. The labour was normal and light chloroform anæsthesia was induced during the last hour. The baby was not at all cyanosed at birth and for the first 14 days of life remained perfectly healthy. At the age of one week circumcision was performed under light ether anæsthesia, and the subsequent progress was excellent for a week. At no time was the child in contact with any patient suffering from any of the symptoms of encephalitis lethargica. Vaccination was not performed.

At the age of 14 days it was noticed that the child was irritable. Then drowsiness set in and it became increasingly difficult to rouse the child, who was admitted to the Hospital for Sick Children at the age of one month. The bowels had been acting normally, there had been no vomiting, no head retraction, and no convulsions.

On admission the baby lay in a very drowsy state, from which it could not be roused even for feeding. No cry could be elicited by any form of stimulation. The left side of the face was paralysed, and there was some slight rigidity of the limbs. The knee-jerks were active and the plantar responses flexor. The pupils were contracted and did not react to light. Ophthalmoscopic examination revealed normal discs. The fontanelle was depressed, the temperature was normal, and the pulse-rate was 130 per minute. No abnormalities could be found in the other organs or systems. The urine was normal and the blood-urea was 42 mg. per 100 c.cm. A superficial nævus about two inches in diameter was present behind the left ear. The respirations ceased on several occasions before death, but artificial respiration was effective in restoring the normal respiratory rhythm until two days after admission, when death occurred. The cerebro-spinal fluid was not examined.



Section of optic thalamus. (× 100.)

The *post-mortem examination*, 20 hours after death, showed no naked eye abnormalities of any organ. The brain was more congested than normal, but there was no special localisation of this congestion in any part of the brain. No sign of any nævoid condition of the vessels of the meninges or brain was present. Portions of the cerebral cortex and basal ganglia were submitted to histological examination. In the optic thalamus definite evidence of the presence of encephalitis of the "lethargica" type was obtained (see figure). The perivascular lymphatic spaces were full of small round cells giving the classical appearance of "cuffing," while there is also a more diffuse but less well-marked infiltration of the brain-tissue between the blood-vessels. Other regions of the brain examined appeared normal.

I am indebted to Dr. Hugh Thursfield for permission to publish this case, and to Prof. J. McIntosh and Dr. J. G. Greenfield for kindly examining the histological sections of the brain.

CONTINUOUS ARTIFICIAL RESPIRATION,

WITH MAINTENANCE OF THE CIRCULATION FOR TWELVE HOURS AFTER APPARENT DEATH.

BY J. BAGOT OLDHAM, F.R.C.S. ENG.,
ASSISTANT SURGEON TO THE NORTHERN HOSPITAL, LIVERPOOL;
SURGEON TO THE GENERAL HOSPITAL, BIRKENHEAD.

Many cases have been reported in which patients who have collapsed during, or shortly after, operation and apparently died, have been resuscitated, and their life maintained for varying periods; yet I consider the following case exceptional enough to be reported.

History of the Case.

A married man, aged 61 years, a railway clerk, was admitted to the David Lewis Northern Hospital, Liverpool (case No. 1894/29), suffering from trigeminal neuralgia. Seven years previously he had had a right lower molar tooth removed on account of a root abscess. Shortly after the extraction the neuralgia started, and at first involved the whole of the right side of the face. Three years later a sequestrum was removed from the site of the previous trouble in the lower jaw, and after this the neuralgia was confined to the right inferior maxillary nerve. The nerve had been injected with alcohol on three occasions with definite, but only temporary, relief. The relief from pain after the third injection lasted only a few weeks.

As life, especially in cold weather, had become unbearable owing to the frequency and severity of the attacks of neuralgia, it was decided to cut the sensory root of the right Gasserian ganglion. On July 13th, 1929, under rectal ether anæsthesia, the ganglion was approached through a subtemporal trephine opening one inch in diameter, and its two maxillary divisions and its sensory root were clearly defined. While the ganglion was being shown to the students the overlying brain suddenly bulged, forcing the brain retractor down on to the base of the skull. It was immediately obvious that an intradural or cerebral hæmorrhage had occurred, and all thought of cutting the sensory root of the nerve was abandoned, and instead, a hook-shaped knife was quickly passed round the inferior maxillary nerve between the ganglion and the foramen ovale, and in this way the nerve was cut.

The dura was now bulging through the trephine hole, and all cerebral pulsation had stopped. The opening in the skull was enlarged with bone forceps and the dura was opened. No blood escaped, but the brain was pushed out and lacerated on the edge of the skull opening, so great was the intracranial pressure. The opening in the skull was still further enlarged, and as some pulsation could now be seen, and as the general condition of the patient did not warrant further interference, the wound was quickly sewn up. The patient returned to the ward at 12.40 P.M., and at that time he was breathing regularly, and the pulse did not give any cause for alarm.

At 1.0 P.M., shortly after the rectum had been washed out to remove the ether, the patient collapsed and stopped breathing. The house surgeon was called to the ward, and found the heart beating very feebly; he started artificial respiration, but at 1.40 as there was no sign of active respiration restarting, and as the heart beat could no longer be felt or auscultated, he ceased his efforts and came to report that the patient had "died."

I saw the patient about 1.50 P.M.; he was then apparently dead. The eyes were dilated and fixed, all the muscles flaccid and the reflexes absent, respiration had stopped and there was no indication that the heart was beating. We decided, however, to make a last effort, and restarted artificial respiration. After a few minutes the pulse began to return and steadily increased in volume, but there was no other sign of life. By 2.15 the heart was beating rapidly (140), but so strongly that there was marked intercostal and epigastric pulsation. All attempts to restart active respiration were in vain, and by 3.30 P.M. the heart had again become weak and the pulse impalpable.

An intracardiac injection of 1 c.cm. of 1-1000 adrenalin was given and within a few minutes the heart was once more beating strongly. After about twenty minutes the force of the heart beat once more began to fade, but a second injection of adrenalin again restored its force, so that, even through the bed-clothes, it was possible to see the precordial and epigastric pulsation.

And so it continued, the pulsation of the heart the only sign of life. Intracardiac injections of adrenalin were given every 15–20 minutes; after each injection the heart beat strongly for ten or more minutes, and then gradually faded away, only to come back promptly after another injection. At 6.0 P.M. the wound was examined; little or no blood had drained out, but the whole area bulged markedly, so the skin stiches were removed. At this moment an injection of adrenalin was given, and immediately there was a burst of hæmorrhage from some of the skin vessels, and artery forceps had to be applied and the vessels ligated. Slight pulsation of the brain was noted. The dressings were replaced.

At 8.0 P.M. the pulse-rate was 140, and in the brachial artery the systolic pressure was 125 and the diastolic pressure 75 mm. of Hg. At 8.45, immediately after the 18th injection of adrenalin, the pulse-rate was 148 and the systolic and diastolic pressures 135 and 80. Though the effect of the injections was still phenomenal it was now noted that the pulse-rate was steadily increasing, and the effect of each injection was not as lasting as the earlier ones had been. Yet even then, if, when the patient was quite pulseless, an intracardiac injection of 1 c.cm. of adrenalin was given, within a minute the heart would be beating so strongly that pulsation could be easily seen in the epigastric region and in the vessels in the neck.

Artificial respiration and the injections of adrenalin were continued until midnight when the 27th and last injection was given. The heart continued to beat feebly until 1.30 A.M. Artificial respiration was then stopped. Except for the ten minutes between 1.40 and 1.50 P.M., artificial respiration was maintained continuously for twelve and a half hours, during which time the patient showed no sign of life other than the pulsation of the heart.

Post-mortem Examination.

We were unable to obtain permission for a full post-mortem, but we examined the lungs, heart, and brain.

The *lungs* were normal. The *heart* was also normal, except for an area of ecchymosis extending from the surface almost through into the heart cavity. This area was about the size of a sixpence, and was situated on the anterior wall of the right ventricle, and had been produced by the numerous intracardiac injections.

Head.—Except for the opening made to decompress the brain there was no opening or puncture in the dura. No hæmorrhage was found on the right side of the brain. There was considerable diffuse subdural hæmorrhage on the left side of the cerebrum and on the front of the pons and medulla. The left lateral ventricle was filled with blood, but there was no hæmorrhage in the brain substance.

Very careful examination of the operation field showed that at no place had the dura been opened, nor was there any hæmorrhage either within or without the dura. The inferior maxillary division of the trigeminal nerve had been cut through close to its origin from the Gasserian ganglion, but otherwise the nerve was intact. There was no bony covering to the carotid canal, but neither the carotid artery nor the superior longitudinal sinus was injured. The cavernous sinus was intact. The right superior cerebellar artery appeared to be severed, but there was no clue as to how this had happened, and I am of the opinion that it was injured in removing the brain.

It is very unsatisfactory that no explanation was found to account for the sudden, dramatic, and fatal hæmorrhage. Exactly the same technique was used in this case as in all our previous cases of section of the sensory root of the Gasserian ganglion, none of which had given rise to any trouble or anxiety.

Lieut.-Colonel C. T. Samman, J.P., R.A.M.C., was recently re-elected Master of the Society of Apothecaries of London for the ensuing year.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—An all-day course in diseases of the chest will be held at the Brompton Hospital from Sept. 9th to 14th. From Sept. 9th to 22nd, under the direction of Dr. Eric Pritchard, a course will be given at the Infants Hospital designed for those engaged in infant welfare work. A course of lecture-demonstrations in psychological medicine will be undertaken by Dr. Porter Phillips and members of his staff at the Bethlem Hospital, on Tuesday and Saturday mornings at 11 A.M., from Sept. 10th to Oct. 5th. An intensive course of medicine, surgery, and the specialties (for men only) will be held at the Westminster Hospital from Sept. 16th to 28th, daily, from 10.30 A.M. to 5.30 P.M. The Prince of Wales's General Hospital, in conjunction with the North Middlesex Hospital, Tottenham, will give a course in gastro-enterology from Sept. 30th to Oct. 4th. Another evening course for the first M.R.C.P. will be held from Oct. 15th to Dec. 6th, on Tuesday and Friday evenings, at 8.30 P.M. in the lecture hall of the Medical Society of London. Full particulars of the above and other courses may be had from the Secretary of the Fellowship at 1, Wimpole-street, London, W.1.

BRITISH MEDICAL ASSOCIATION.

ANNUAL MEETING IN MANCHESTER.

(Continued from p. 479.)

SECTION OF MEDICINE.

PATHOGENESIS AND TREATMENT OF ASTHMA.

Dr. A. F. HURST (New Lodge Clinic) remarked that this was the sixth occasion on which asthma had come up for discussion at an annual meeting, and while he doubted whether any real advance in knowledge had been made, yet he believed the disease was better understood now than heretofore. An appreciation of the variations, within the limits of the normal, of the chemical constituents of the body fluids afforded a basis upon which inherited constitutional tendencies might be explained. The pathogenesis of asthma lay in slight deviations from average blood chemistry whereby vagal overaction was favoured as against the opposing sympathetic effects. Thus arose muscular bronchial spasm and mucous secretion producing the classical changes. Suprarenal exhaustion, he thought, played no insignificant part, as shown by the increased liability to asthma as the result of fatigue, which partially explained week-end, menstrual, and pre-holiday attacks. The part played by adrenalin was demonstrated by the low blood-sugar content, the low blood pressure, and the effect of adrenalin treatment. The hypersensitiveness made familiar by the cutaneous reactions had led to little result except for the help given by proteins in children and pollens at all ages. The nose was important from the point of view of restricted air inlet; a distended stomach or rectum might be the source of an attack. The psychological factor of expectation was potent.

Of the many forms of treatment only two approached a cure—namely: (1) Careful dietary as applied more particularly by Dr. Adam to children, and (2) residence in the Alps at a height of 4000 ft. or more. The effect of the latter was due more to atmospheric rarefaction than to freedom from dust and allergens. Nasal hygiene involved three factors: (*a*) Removal of sepsis from the sinuses; (*b*) securing a free airway; (*c*) destroying the asthma-reflex area. Biochemistry seemed to offer some prospect of cure, but this aspect had not yet been fully developed. A cheery optimism did much to help the psychological factor in many patients; reflex exciting causes, especially from stomach and rectum, always needed careful attention. The treatment of the paroxysm remained, and for this adrenalin was a specific. The principle of giving the patient instructions and a hypodermic syringe was maintained and the method of continuous adrenalin administration in status asthmaticus was described. Ephedrine had proved more useful in mild hay-fevers than in real asthma.

Dr. JAMES ADAM (Glasgow) reported his experience in the treatment of 1100 cases of asthma over a period of 30 years. He believed that their origin was: (1) toxic, (2) dependent to a large extent on nasal conditions. The toxic effect was due to combined absorption of nitrogenous poisons from the gut and to error in nitrogenous metabolism. Excessive carbohydrates in the diet were often the determinant. Over-feeding and under-exercise were the chief factors in week-end attacks. The periodicity of nocturnal, weekly, and menstrual attacks all indicated a metabolic origin. The eczema and urticaria commonly associated with asthma were due to the same cause and amenable to the same treatment. A large number of cases occurring before the sixteenth year could be cured if mouth-breathing was corrected. Oriel's work was referred to as supporting the theory of nitrogenous metabolic errors. The disappearance of eosinophilia along with the asthma in acute pyrexias was due to increased adrenal activity, which was also the basis of success in the cold bath or cold douche treatment. The frequency of a family history in asthma was attributed by the speaker to identity of environment rather than to inheritance of defect.

Prof. R. J. S. McDowall (London) showed how asthma could be induced by: (1) Local irritation, as by inhaling irritant gases; (2) chemical stimulation, as by injecting bodies of the histamine group; (3) nervous stimulation, as shown by Brodie and Dixon, and reflex from stimulation of the nose; (4) psychic stimuli via the vagus, on the same basis as salivation at the prospect of food. The part played by the vagus in asthma was further indicated by the associated vagal phenomena of increased bronchial secretion and occasional colitis. Week-end and digestion asthma, the low blood pressure, slow pulse, low blood-sugar curve, and eosinophilia were all, possibly or probably, vagal in origin. The two asthma camps, championing nasal defects or allergy, were both concerned with vagal activity, and he reported some recent experiments of his own, which showed that a foreign protein (peptone) injected into the circulation enormously enhanced the capacity of pilocarpine to stimulate the vagus. Hess had for years stated that asthmatics were abnormally sensitive to pilocarpine, and it was known that foreign proteins increased the amino-acid content of the blood as well as causing a temporary constriction of the bronchioles. In this way the widely varying causes and cures of asthma fitted into a more or less intelligible physiological picture.

Dr. G. H. Oriel made the following points: Asthmatics do not all belong to one type. In asthma associated with eczema, migraine, and urticaria the van den Bergh reaction is often positive, the amino-acid is high, urates are deposited in the urine, and the blood-sugar may be low. In uncomplicated asthma the van den Bergh reaction is usually negative; the amino-acid may be high, but the blood-sugar and pressure are low, pointing to under-action of the sympathetic. A complex nitrogenous substance may be extracted from the urine during paroxysms, and this gives positive skin reactions with the patient from whom it is extracted. This substance is probably specific. In the first biochemical type treatment should be directed to the gut and liver; Adam's detoxicating treatment has proved beneficial, especially with the addition of glucose to the diet, as suggested by Osman, along with spirits of ammonia in one drachm doses, especially in children. In the second type treatment, in addition to attacking the diathesis, should be directed to stimulating the sympathetic by thyroid.

In the ensuing discussion Dr. Watson-Williams reiterated his belief that asthma arises from a nasal reflex, while Dr. F. T. Harrington emphasised the factor of nasal sepsis and the need for general detoxication, while training in diaphragmatic breathing was important. Dr. Wharry was also a believer in nasal sepsis as a cause, but thought some method of reducing the general sensitivity of the nervous system was requisite in many cases. Dr. Camps recorded his experience of the inhalation of adrenalin vaporised by an oxygen stream, and claimed this as a simple and safe method which patients could easily manage for themselves.

SECTION OF SURGERY.

Papilloma of the Bladder.

Mr. J. B. Macalpine (Manchester), who opened the discussion, defined a papilloma as a tumour made up of hypertrophied papillæ. Two problems invited brief preliminary discussion: (1) Do all papillomata, if left to themselves, eventually undergo malignant transformation? Many surgeons, he said, regarded all papillomata of the bladder as premalignant tumours, an attitude which produced the necessary solicitude in their treatment. (2) How shall the nature of the growth be decided? Pathological diagnosis was extremely uncertain; in the experience of many surgeons recurrence might follow the removal of tumours regarded as simple, and vice versa. Mr. Macalpine said he had come to rely solely on cystoscopic data for his diagnosis of these growths; those he judged to be simple he treated with perurethral diathermy, and those which he suspected of being carcinomatous by open operation. The longer and more delicate the villi the more benign the growth. When surface necrosis appeared malignancy was indicated. In the less benign varieties the layers of epithelium were more numerous and the tumour coarser and paler. The appearance of the pedicle was important; a thin flexible and long pedicle occurred with benign papilloma; a stiff, stumpy one indicated malignancy. The type of papilloma that was sessile over a wide area had a very unfavourable outlook. If such had been treated by diathermy some inflammatory swelling might remain closely resembling true neoplastic infiltration; regarding diagnosis, repeated cystoscopy was the only way of excluding this "pseudo-carcinoma." In about one-third of all patients papillomata were multiple, with a tendency to return, and the prognosis after operation was not so good.

In deciding on treatment perurethral diathermy was unanimously agreed to be most suitable for simple papillomata and open operation for malignant growths. When there was doubt as to the nature of the tumour, and diathermy was not plainly succeeding, open operation should be undertaken without delay. In some patients cystoscopy was impossible owing to the extent of the growth and the accompanying cystitis or hæmorrhage. In these cases valuable information might be obtained by filling the bladder with a radiographically opaque solution, when X ray examination might demonstrate the outline of any growth present. In this series six cases occurred in workers in aniline dye, which was almost certainly an exciting cause. Prior to the onset of the neoplasm in these workers there had been a premonitory period in which the patient suffered from symptoms of cystitis with occasional hæmaturia. Dr. T. H. Wignall had drawn attention to the long period of contact necessary, 20 to 30 years being the average.

Mr. Macalpine outlined his method of treatment, stating that bipolar diathermy was generally used in this country for small benign papillomata. At the end of about two to three weeks benign papillomata should be definitely smaller and have separated, their appearance simulating granulation tissue. If slough still adhered to the growth malignancy must be suspected. If the growth was malignant excision offered the only hope, and in order to remove the lymphatics which ran in the deep layers a generous area of bladder wall must be removed after mobilisation of the bladder, the operation wound being protected by swabs soaked in silver nitrate (1 in 1000). He concluded by remarking that cases of symptomless hæmaturia should be submitted to immediate cystoscopy.

Mr. Henry Wade (Edinburgh) urged the importance of immediate cystoscopy for all cases of symptomless hæmaturia, and stated that the mucous membrane adjoining the stem of the papilloma should be observed, as at times there was a roughened area round the base of the papilloma from which fresh tumour tissue might grow, hence it was important to destroy this. He regarded perurethral diathermy as the method of choice for the treatment of the majority of cases of papilloma, and thought the growth should be destroyed at one sitting under a general anæsthetic, warning the patient that a secondary hæmorrhage might occur later when the slough separated, which latter might with advantage be removed in order to obviate the possibility of stone formation. He regarded the following cases as suitable for open operation: (1) Growths of the size of a walnut or larger. (2) Growths situated round the vesical orifice. (3) Cases in which there was a tumour with vesical spasm in persons aged 50 and over. Spasm suggested infiltration. (4) Cases with accompanying disease, such as enlarged prostate, where there was fear of infection. In malignant infiltration the growths were found to be more sessile, the villi were fused, and the surface irregular; for these open operation should be performed. If the growth could be picked up when the bladder was opened then he did a mucous resection of the growth. If the growth was fixed (it was important to make sure that the growth did not arise from, e.g., the bowel) partial cystectomy was the operation of choice. In these cases, if the ureteric orifice was involved, the speaker left the divided ureter just in contact with the sutured bladder when communication was re-established by natural processes. Complete cystectomy must be done in stages; first cystotomy to confirm diagnosis, then operation for disposing of the ureters either externally or preferably, into the bowel, and finally the bladder was dealt with.

Mr. **Swift Joly** (London) described treatment and its results in cases with no malignant infiltration; he included cases with thickened epithelium as he did not regard these as malignant. If the tumour was superficial the correct treatment was perurethral diathermy, but if there was even slight infiltration he opened the bladder and did either wide resection or open diathermy, inserting radium round the scar. Before 1913 all cases of papilloma of the bladder were treated by open operation, and he gave an account of 30 cases of single papilloma thus treated with four recurrences, and nine cases of multiple papilloma which recurred, all being fatal. Of 25 cases of single papilloma treated by perurethral diathermy six recurred more than five years afterwards. Multiple growths were common, but with perurethral diathermy good results might be ultimately expected with care and patience. If there was recurrence after open operation for papilloma, the patient was in a worse condition than before, for the secondary growths were often multiple and sessile. Mr. Joly described his retrograde cystoscope, including its uses for growths near the internal meatus and on the anterior wall of the bladder; he used continuous irrigation in the diathermy of extensive growths. For growths in the posterior urethra and in the internal meatus he used a posterior urethroscope.

Mr. **R. J. Willan** (Newcastle-on-Tyne) said that of 68 cases under his care 53 were males and 15 females; their age varied from 23 to 77. In distinguishing between simple and malignant papilloma he thought the best help was obtained from examination of the pedicle, although pathological diagnosis was often fallacious. Of the 26 fatal cases of his own the following were the causes of death: 6, general dissemination; 6, cachexia; 2, local extension into rectum and vagina; 2, hæmorrhage; 1, surgical kidney; 1, heart failure; 1, post-operative shock; 7, cause unknown.

Prof. **Andrew Fullerton** (Belfast) described his technique of cystectomy, which is to cut the ureters above the bladder, not preserving their orifices (as some do), and stressing the importance of drainage by means of a rigid tube passing through the levator ani muscle and the ischio-rectal fossa.

Mr. **H. H. Rayner** (Manchester) gave an account of two cases of extensive carcinoma of the bladder, both apparently cured after suprapubic cystotomy and insertion of radium.

Short Papers.

Dr. **A. T. Bazin** (Montreal) gave an account of paraffinoma of the rectum simulating carcinoma in a case which was referred to him and which previously had prolapsed piles treated by a course of paraffin injections. The interest of this case lay in the differential diagnosis from carcinoma and in the treatment, which consisted in excision of the affected bowel, the ends being joined up with preservation of the sphincter. In the ensuing discussion Mr. J. P. Kilner condemned the use of paraffin injections, mentioning a case of extensive epithelioma of the skin after injections of the chest.

Prof. **Dean Lewis** (Baltimore) gave an account of congenital arteriovenous fistulæ which presented a very different problem from the treatment of the acquired condition resulting from injuries. The former, by reason of the large number of anastomotic communications, at times baffled treatment.

SECTION OF OBSTETRICS.

Surgical Tendencies of Modern Obstetrics.

Prof. **E. Essen-Möller** (Lund, Sweden) said the art and science of midwifery was developing in a manner as important as it was interesting. Physiological research was investigating the biology of pregnancy in normal and pathological conditions. X rays, pelvic measurements, examinations of urine were being applied to detect anomalies and apply prophylactic treatment to lessen the risks to mother and child. And now surgical interference was increasingly taking the place of the older obstetrical methods. In placenta prævia the only resource used to be tamponade until version could be performed. In eclampsia venesection and chloroform were the only means of avoiding new fits. Prophylactic treatment was well-nigh unheard of. The merits of the old midwifery must, however, not be disregarded. The most important advance dated from the revival of the classical Cæsarean section and the invention of the vaginal section; by the latter means it was possible to empty the uterus at any period of pregnancy or labour. The risk or value of an operation ought not to be estimated solely on the primary results, infection, embolism, and the like. The secondary risks were just as important, as, for example, the risk of thinning or rupture of the scar after Cæsarean section, and fear in subsequent pregnancies. Prof. Möller quoted Hirsch, of Berlin, who advocated surgical interference in normal labours in order to avoid examination and risk of infection, alleging that this was the only way of diminishing maternal mortality. He did not agree with Hirsch, although he admitted that owing to the rush for more speed Cæsarean section was now being abused. Labour, he said, was a physiological process in which there should be no interference without due caution and consideration.

Prof. **A. Donald** (Manchester) said he represented the old school; there had been, he thought, more innovations and greater advances in midwifery than in gynæcology. When he was a house surgeon at St. Mary's Hospital the visiting surgeons took little interest in midwifery, most of which was conducted in the patients' houses. Maternal mortality was low then probably because they used antiseptic methods rather than aseptic. The introduction of pituitrin into obstetric practice had brought with it dangers of its own. The greatest advance of all had been in the provision of careful antenatal supervision.

Prof. **R. J. Johnstone** (Belfast) said his maxim was avoid interference. Operation was now so safe that it required more courage to refrain than to operate. He did not think it practicable to carry out aseptic midwifery in the patients' houses, and he always taught his students to use antiseptics.

Prof. **R. W. Johnstone** (Edinburgh) thought that Prof. Möller's paper should have been entitled "operative" rather than "surgical" tendencies, as surgical technique, especially the use of antiseptics, was always adopted in obstetrics. He agreed with those who advised antisepsis in domiciliary treatment. The Edinburgh school did not favour vaginal hysterotomy for emptying the uterine contents, as they had not had satisfactory results. He referred to abdominal hysterotomy for cases of hydatidiform mole and pernicious vomiting of pregnancy.

Dr. **B. Solomons** (Dublin) said that a person practising gynæcology could not be a specialist in obstetrics. By patience and observation in labour many operative procedures could be avoided.

Prof. **Möller**, in reply, said the possibility of Cæsarean section was a great asset to the elderly primigravida, with a breech presentation, where the life of the child was a little uncertain if delivered through the natural passages; he advocated great caution before resorting to it as a routine method. In Sweden, apart from versions and forceps, operative treatment was carried out in a hospital or nursing home.

The Gynæcologist's Training.

Prof. **T. S. Cullen** (Baltimore) said that every surgeon, if he was to get the most out of his work, must have had a thorough grounding in general pathology and in the surgical pathology of the particular subject which was to become his life-work. He outlined the system adopted at the Johns Hopkins Hospital. Each year five men from the graduating class were assigned to the gynæcological department, during which year they had charge of patients, took histories, and assisted at operations. At the end of the year one of these was selected for promotion; he then became an assistant to the professor of pathology for the next year, when he had ample opportunity to make autopsies, gain knowledge of gross pathology, and familiarise himself with anatomy. He then returned to the gynæcological department, examined and described the material coming from operations, with time to devote to the investigation of gynæcological problems. The fourth year he was made first assistant and for the final year resident gynæcologist in full charge of the department, when in addition to assisting the visiting surgeons, ample opportunity was afforded for doing both major and minor operations. Every gynæcologist should be able to treat any abdominal emergency, and he gave a large series of cases he had encountered where such knowledge was essential.

Dr. J. W. Riddel (Plymouth) said that for those who intended to adopt gynæcology and obstetrics as a specialty, and were not fortunate enough to be attached to teaching hospitals, it might still be possible to gain the necessary surgical experience whilst carrying on general practice, where the necessary breadth of mind was also acquired.

Prof. R. J. Johnstone agreed that the gynæcologist should be ready to deal with all emergencies; other lesions were often met with when the diagnosis of a pelvic lesion had been made. All gynæcologists should, he thought, do a year's demonstrating in the anatomy department and also be obstetricians.

Prof. J. P. Maxwell (Pekin) said he had been both an obstetrician and a gynæcologist; it was only a gynæcologist with clinical experience who could estimate the value and give an opinion on curettings.

Dr. A. E. Giles (London) thought anyone going in for gynæcology should have a broad preliminary training in obstetrics and gynæcology, specialism to come later. He considered diagnosis and experience more important than actual knowledge of abdominal surgery as most operative procedures were similar, and a surgeon accustomed to a certain surgical technique could easily follow others.

Prophylactic Treatment of Albuminuria.

Dr. L. C. Rivett (London) dealt with the prophylactic treatment of cases which had had albuminuria in a previous pregnancy. The publications of Young and Gibberd had, he said, stimulated this attempt to guard against permanent renal damage. The essential feature of the treatment was to maintain the urine throughout the whole of subsequent pregnancies at a minimum alkalinity of pH 7·7. In order to achieve this, large doses of alkali were given by mouth. To guard against over-dosage it was advisable to estimate the bicarbonate content of the blood plasma at repeated intervals, especially if any change of the original dose was indicated. The normal plasma content in pregnancy was 0·030 molar concentration. In 85 per cent. of women, however, there was a considerable reduction, the average being 0·0247. The dose found to be safe and effective was usually about 400 grains a day of equal parts of sodium bicarbonate and potassium citrate, but this should be varied according to the reaction of the urine. In some up to 780 grains had to be given, whilst in others it might be reduced to 1–2 drachms. Especial attention should be paid to the bowels, diet, and hygiene, while strenuous exercise was to be avoided. Dr. Rivett gave the clinical histories of a series of 14 cases submitted to the treatment.

Dr. J. Young (Edinburgh) thought the treatment described held out hope for these cases and would probably throw light on the ætiology of the albuminuria of pregnancy. He did not agree that a great many of these cases sustained permanent renal damage as estimated by kidney function tests; he found it only occurred in about 8 per cent. There was evidence of recurrence in about 50 per cent. of the cases who subsequently became pregnant, and in these the tendency to permanent renal damage was greater.

Dr. A. Crook (Norwich) had used alkalis in many cases of albuminuria with good results. Some cases known to him as chronic nephritic with high blood pressure had shown no albuminuria when they subsequently became pregnant, although there was a tendency to abortion.

Dr. H. L. Greer (Belfast) said he had given alkalis to pregnant women for heartburn and had noticed that they were more comfortable in the latter part of pregnancy. The incidence of eclampsia was diminished in cases treated with alkalis.

Dr. F. Lacey (Manchester) said he had been regularly examining urines antenatally, and had found a large number containing the colon bacillus. In his experience pyelitis was a common condition.

New Inventions.

SURFACE SUTURES.

I have devised what may be described as surface sutures ("Surfasutes") for approximating the cut edges of wounds without stitching. They are intended to largely do away with the necessity for using clips, or a needle to suture lacerated wounds. The device consists of strips of specially adhesive plaster cut in various shapes and sizes, each furnished with small smooth eyelets. As shown in Fig. 1 after the laceration has been cleaned, sterilised, and dried, they are laid in interrupted position on each side of the wound, the eyelets being about half an inch distant from the cut edge. A sterile, half-curved needle, threaded with silk, or silkworm gut, is then passed through the eyelets instead of the skin and the edges of the wound can be accurately approximated as shown in Fig. 2. There are many obvious advantages: sterile surface sutures, needle and silk, or silkworm gut, can be carried in the doctor's bag and are always ready for immediate use; the pain of stitching is entirely done away with; no stitch scars are left; there is no danger of stitch abscesses; dressings can be changed without disturbing the surface sutures; the plaster strips are antiseptic and specially adhesive, and therefore cannot slip; and the smooth surface of the eyelets is in contact with the skin and therefore there is no chafing. The eyelets can be raised for the ready introduction of the sutures because the adhesive surface does not run beyond them, but is enfolded to strengthen their insertion. Messrs. A. de St. Dalmas and Co., Ltd., Leicester, are the manufacturers.

Reviews and Notices of Books.

OTO-RHINO-LARYNGOLOGY.

The Nose, Throat, and Ear and their Diseases. In original contributions by American and European authors. Edited by CHEVALIER JACKSON, M.D., Sc.D., LL.D., F.A.C.S., Professor of Bronchoscopy in the University of Pennsylvania; and GEORGE MORRISON COATES, A.B., M.D., F.A.C.S., Professor of Otology, University of Pennsylvania Graduate School of Medicine. London and Philadelphia: W. B. Saunders Company. 1929. Pp. 1177. 60*s.*

THIS important work is one of those written by a very large number of experts in various departments of their specialty. It retains a predominantly transatlantic outlook, for of the 76 contributors, only five are European, three hailing from Great Britain and two from France. Each section is written by one who has interested himself specially in the subject discussed, and the whole is edited by men of such eminence in laryngology and otology that its appearance is an event of some importance. Since the book is full of valuable detailed information, contributed by acknowledged experts, it seems ungrateful to criticise defects inherent in any work of this type; but some of them could doubtless have been mitigated by a vigilant editorial survey before publication. There is considerable overlapping and unevenness in the treatment of different subjects, and some of the descriptions are disappointingly terse for a book of this size. For example, the section on tonsillectomy teaches that "before proceeding to the removal of the other tonsil it is essential that all bleeding should have been completely arrested," and that "arterial or venous hæmorrhage of any moment should be arrested by ligation." A method of ligation is shown in Fig. 179, but although several ingenious devices are in general use among laryngologists for this purpose there is no description of any method in the text. No account of the treatment of cancer of the larynx and pharynx by radium and deep Rontgen ray therapy, which has lately made considerable progress, is included in the book, and the methods of operation included under lateral pharyngotomy are not set out in sufficient detail. As an instance of the difficulty of adjustment of material under multiple authorship, we note that intubation is described very clearly and at length early in the book under the treatment of diphtheria, and tracheotomy towards the end, after laryngectomy. The important question whether intubation or tracheotomy is the best method of coping with obstruction in diphtheria is dismissed in the earlier section with the words: "Laryngeal diphtheria may require intubation on tracheotomy; the operation of choice is usually intubation." We prefer the advice offered later in the book: "If the case is one of diphtheria and there is a skilled intubator who will not only introduce the intubation tube but will remain in the house to reintubate in case the tube is expelled, intubation is worth consideration; otherwise it is not." The book is well produced, and the editors are to be congratulated on the general plan adopted. Most of the illustrations are excellent, a bibliography concludes each section, and, most important in a work of this scope, the index is full and adequate.

SURGICAL INFECTIONS AND INFLAMMATIONS.

Trattato generale e speciale delle infezioni o infiammazioni chirurgiche. Vol. I. By DEMETRIO B. RONCALI, Director of the Royal Institute of Surgical Pathology at the University of Naples. Naples: Stabilmento Tipografico I.N.A.G. 1929. Pp. 336. L.65.

THIS volume is devoted to general infective or inflammatory processes; a successor will treat of acute and subacute processes such as tetanus, erysipelas, gas gangrene, and suppuration in general, and a third volume with chronic diseases such as syphilis, actinomycosis, epithelioma, and tuberculosis. The preface contains the astounding statement that "clinical medicine persists in asserting with no uncertain voice, and without requiring the permission of any Imperial or Royal Institute, or national or international commission for the study and treatment of cancer, that all malignant neoplasms having a beginning, course, and result identical with those of the majority of processes of parasitic origin cannot logically be otherwise than infections or inflammations, *sui generis.*" A second no less astounding statement is found in the historical survey which precedes the classification of surgical inflammations—viz., that Harvey was not the discoverer of the circulation of the blood, but that following on the observation of the non-permeability of the cardiac septum and consequent perception of the pulmonary circulation by Realdo Colombo, the real discovery of the general circulation was to be attributed two years afterwards to Andrea Cesalpino.

The leading idea of this work seems to be that all surgical inflammations are really infections and due to parasitic action which engages in a struggle for life (1) at the site of infection, (2) in the parenchymatous organs, and (3) in the torrent of the sanguineous and lymphatic circulation. Such being the main conception much space is given to recording the views of numerous observers—the index of these authors contains considerably more than 500 names. The work shows considerable erudition, but it may be doubted whether any real advance in surgical pathology is made in its pages. Dr. Roncali's conclusions seem to be that the struggle for mastery at the site of infection takes place between the host, with its histiogenic and hematogenic cells and its antibodies, and the parasite with its bacterial cells and antigens. That this struggle may end in the victory either of the host, resulting in cure, or of the parasite when organisms invade the blood, is no new conception in pathology and this is the main thesis here developed.

THE CLIMACTERIC.

The Critical Age. By GREGORIO MARANON, Professor of Medical Pathology in the Madrid General Hospital; Member of the Royal National Academy of Medicine. Translated by K. S. STEVENS. Edited by CAREY CULBERTSON, A.B., M.D., F.A.C.S., Associated Clinical Professor of Obstetrics and Gynæcology, Rush Medical College of the University of Chicago. London: Henry Kimpton; The C. V. Mosby Company, St. Louis, U.S.A. 1929. Pp. 425. 18*s.*

THIS is an English translation, revised by the author in 1925 from the second edition of Prof. Maranon's well-known work, originally published in Spain in 1918. It is curious that an event of such obvious importance in the life of women as the climacteric has received so little scientific attention in the past. A full account of almost any rare disease would be easier to find in medical literature than a discussion of the clinical aspects and physiopathology of the climacteric. Prof. Maranon points out that the climacteric is not merely a syndrome of genital insufficiency, as was thought until recently, but is the pathological consequence of a complex and constant endocrine crisis like that of puberty, the glandular elements of which can be made out with some degree of accuracy. This greater knowledge of the mechanism of the crisis enables us to interpret clearly and to treat correctly many phenomena which were previously obscure. The classic concept of the climacteric as a simple genital incident disappears. In its place appears the more comprehensive concept of the "critical age," that of a long period of life in either sex the nucleus of which is the genital disturbance, but in the development of which all organic activities participate. The author's comprehensive outlook is well illustrated by a review of some of the chapter headings of the present volume. He first describes the ovarian, thyroid, suprarenal and hypophysical factors, and gives an account of the rôle of the vegetative nervous system in the symptomatology. There are other chapters on the psychological problems of this period, the psychic, genital, metabolic, and endocrine symptoms. Finally, a full account is given of the artificial or surgical climacteric, and every aspect of treatment is considered. The book is conceived from the point of view of the general practitioner, but will also be of considerable interest to gynæcologists.

NEUROLOGY.

Revision de la doctrine des localisations cérébrales. By Dr. R. BRUGIA, Professor in the University of Boulogne. With a preface by Prof. PIERRE MARIE. Paris: Masson et Cie. 1929. Pp. 100. Fr.24.

WE are always a little dubious of iconoclastic revisions, especially where they concern any body of doctrine built up on the laboriously collected evidence of generations. It is a priori unlikely that in these modern times such evidence should be based on mistaken ideas throughout, or that had it been built up on insecure foundations this would not have been recognised long since. Prof. Brugia invites us to believe that there is no such thing as a nervous "centre"; that psychical, speech, inhibitory, and sensorimotor "centres" are unreal; that no collections of ganglionic cells effect some "magical" action; and that their place is taken by "zones in which spinal or cerebral receptoric activity precipitates itself, without transformation, in terms of movements." Spinal and cerebral "reflexes" indicate the free passage (more or less direct, more or less rapid) to the organs of expression, of activities derived from the mechanisms of sensibility. It may be so. But after all, what is meant by a "centre," and what by "localisation"? What is the difference between a "centre"—misleading word—and a "zone"? And what of the accumulated clinicopathological data in respect, say, of the visual cortex? What of Jacksonian epilepsy? If there is no specificity as regards neural cerebral mechanisms, nothing but a non-specific "electro-colloidal change," why should any sufferer remain blind, deaf, halt, or aphasic as a consequence of cerebral lesions? Unfortunately, we have ample clinical evidence that compensation and substitution are not prominent characters of cortical function.

Neurological Examination. By CHARLES A. MCKENDREE, A.B., M.D., Associate Physician, Neurological Institute of New York. London and Philadelphia: W. B. Saunders Company. 1929. Illustrated. Pp. 280. 15*s*.

THERE are many small handbooks for the tyro in neurology to slip in his pocket and refer to at the bedside or in the out-patient clinique, until such time as his acquaintance with neurological method becomes second nature and book aid superfluous. This newcomer is welcome for its clarity and completeness. Probably none has ever been written in which the expert has not found something to criticise and something to amend, and Dr. McKendree's is no exception. But it serves its purpose well.

Text-book of Clinical Neurology. For Students and Practitioners. By M. NEUSTAEDTER, M.D., Ph.D., Visiting Neurologist, Central Neurological Hospital, Welfare Island. Philadelphia: F. A. Davis Company. 1929. Pp. 692. $6.

Dr. Neustaedter covers the field of clinical neurology in compendious fashion, his working arrangement being mainly semiological. Under the headings Spastic Paralyses, Flaccid Paralyses, Ataxias, Trophic Disorders, and so forth, he manages to include a great deal of useful knowledge, described in precise terms and amplified by a liberal supply of illustrations. The method, doubtless, has its merits, but its disadvantages are no less apparent. The thalamic syndrome is raked in under spastic paralyses, amyotrophic lateral sclerosis under flaccid paralyses, Charcot-Marie-Tooth amyotrophy under diseases of the cranial nerves (itself a subdivision of flaccid paralyses), facial neuralgia under tremors and spasms. Such classifications are highly unsatisfactory, but after all tabulation is of minor importance. We have noted but few errors or misleading statements. It is scarcely accurate to say in a case of Bell's palsy that if taste is abolished on the anterior two-thirds of the tongue "we are dealing with a middle ear affection." Rod-cells are not, as a matter of fact, "pathognomonic of paresis." Why the "functional neuroses" should be limited to hysteria and neurasthenia is not clear. The clinical descriptions embody the most modern investigations and deserve high praise.

MENTAL DEFICIENCY (AMENTIA).

Fifth edition. By A. F. TREDGOLD, M.D. Durh., F.R.C.P. Lond., F.R.S. Edin., Lecturer on Mental Deficiency, London University. London: Baillière, Tindall and Cox. 1929. Pp. 535. 25*s*.

THIS valuable standard work has now attained its majority, the first edition having appeared in 1908. Since that time great changes and developments have occurred in this field. The importance of mental deficiency as a national handicap and disgrace is becoming more and more fully recognised; its causes, manifestations, and incidence are being studied by an increasing number of gifted and devoted workers, and the efforts which have been initiated to combat it are rapidly gathering momentum. Dr. Tredgold's book has developed with the times, and represents a thoroughly up-to-date survey of the position as it is to-day. Since August, 1922, when the fourth edition appeared, two important events have occurred: the alterations in the legal definitions made by the Act of 1927, and the publication by the Joint Committee of Dr. E. O. Lewis's report on the number and condition of defectives in this country. The treatment of this material has meant a complete revision of the book, and, although the general plan remains the same, many chapters have been much altered, and some have been entirely rewritten. Several illustrations have been added. Dr. Lewis's figures indicated that the number of defectives in England and Wales in 1927 was approximately 314,000, or 8 per 1000 of the population. This represents an apparent increase of no less than 100 per cent. on the figures of the Royal Commission of 1904. Dr. Tredgold's analysis of this striking difference deserves close attention, since the question of whether the incidence of mental defect has really doubled or whether the increase can be accounted for in other ways is very important. He concludes that, although it is not conceivable that the number of defectives has actually doubled, there has nevertheless been a relative and an absolute increase in mental deficiency in the last 20 years. This growth in the severity of the problem, with the corresponding growth in public concern, render even more vital the necessity for well-informed leadership of the kind represented in this book.

THALLIUM ACETATE TREATMENT OF RINGWORM.

Le traitement des teignes par l'acétate de thallium. By Prof. J. G. URUEÑA, Clin. Dermat. Med., Faculty of Mexico. Paris: Masson et Cie. 1926. Pp. 144. Fr.16.

THE author's reasons for devoting a book to a subject on which the bibliography threatens to become voluminous are that European writers are apt to ignore the initial impetus given to it by Mexican workers, that many authorities are inclined to condemn a method which is fraught with certain risks, and that it appeared advisable to concentrate all that is known of the subject in an accessible and readable form. Prof. Urueña and his Mexican confrères, Cicero, Salvador, Peter, and others certainly deserve credit for having brought the method into the realm of practical therapeutics, but it must not be forgotten that without the pioneer work of Buschke, who first determined the dosage, and whose investigations were carried on for a period of over 20 years, thallium acetate treatment would still be under the strictures imposed on it by Sabouraud in 1913 (Les Entretiens Dermatologiques). The subject is considered in six main sections. Chemical and experimental aspects are first dealt with; a report follows on animal autopsies, well illustrated by photomicrographs, and the remaining sections are devoted to the biological, therapeutic, and toxic reactions in the human subject. It is claimed that a dose of from 5–8 mg. per kilo body-weight is non-toxic for children between the ages of 2 and 12 years. A dose of more than 8 mg. per kilo should not be exceeded although experiments on the guinea-pig and rabbit demonstrated that fatalities do not occur until a dose of 14 mg. per kilo is reached. A second dose, in cases of failure to epilate should not be given when the first produced toxic symptoms, and only after a considerable interval (three months according to general opinion). The value of thallium acetate in the treatment of tinea tonsurans is undoubted, but it is an indisputable fact that the drug attacks healthy hairs in preference to the infected. Prof. Urueña would have earned more appreciation if he had devoted a section to the after-treatment, which is laborious and cannot be left to subordinates; without it failure to cure is almost inevitable. Although much has been written in this country on the subject, not a single British writer finds a place in the bibliography.

PUBLIC HEALTH.

Collected Studies from the Bureau of Laboratories of the Department of Health of the City of New York. Vol. X. Covering years 1920-1926. New York: Department of Health. Pp. 583.

DIPHTHERIA ranks with pneumonia and diarrhœa as a highly prevalent and fatal malady among children of all classes and races in New York. This volume of collected papers from the Department of Health of the City of New York contains, among other matters, reprints of many weighty contributions to the literature of prophylaxis. Dr. William H. Park and Dr. Abraham Zingher are the chief authors, the former being one of the pioneers of therapeutic measures against diphtheria on modern lines over 30 years ago. Most of the papers were first published in 1925, but the facts they contain will bear reiteration.

Taken as a whole they comprise a plea for the educational propaganda necessary to enable mass immunisation of the children of a community against diphtheria to be carried out. And the fact that the weapon for this mass immunisation is now in our hands is eloquently expounded. The first consideration is the Schick test. Provided the technique is correct and reagents are accurately arranged—desiderata often notably lacking—the Schick test appears to be almost infallible. After the age of 2 a negative Schick test indicates complete and lasting security from diphtheria. Indeed, so emphatic are certain authors in this belief that they contend that a patient who has recently shown a negative Schick test and who, nevertheless, presents a faucitis, with diphtheria bacilli recoverable from the lesion, can be classed as a carrier who has by chance developed a sore throat. In other words, a child who has shown a negative Schick test will not suffer from diphtheritic toxæmia. One of the papers contains an analysis of 150,000 Schick tests. By this immense survey the liability to diphtheria was shown to be anything from 60 per cent. to 80 per cent. of all children, the lower figure being given by the returns from schools in less salubrious districts. As a guide to the need of giving immunity by toxin-antitoxin injections the Schick test has its limitations. It is not significant under six months, because at that age a child almost always has a fair amount of naturally inherited immunity. In the age-period of 6 to 24 months the Schick test, though infallible as a guide to the state of immunity or otherwise at the time it is done, is not an accurate guide to the desirability or otherwise of toxin-antitoxin injections because in this age-period the natural immunity is waning and changing. From 2 years to 5 years is the period of *greatest susceptibility to the disease.* The patient's natural immunity having now become stabilised, the Schick test can be used as a guide to the need of therapeutic immunisation. In later childhood the same remarks apply.

In the reports of therapeutic immunisation an enormous mass of data is presented. They should therefore be studied in the original by all engaged in public health. Therapeutic immunisation consists of three injections of a suitable toxin-antitoxin mixture at weekly intervals to children who are shown by the Schick test to be susceptible to diphtheria. In about 85 per cent. of all children so treated immunity will develop in less than six months, and it will last at least six years. Unfortunately for the children, but fortunately for the purposes of statistical survey, the workers were denied the facilities for therapeutic immunisation in 90,000 susceptible children. These served as controls against another group of 90,000 children whose parents consented. The value of therapeutic immunisation was shown by the overwhelming preponderance of morbidity and mortality in the unprotected group.

LES PHÉNOMÈNES DE RÉPERCUSSIVITÉ.

By Dr. ANDRÉ THOMAS, Physician to the Saint Joseph Hospital, Paris. Paris: Masson et Cie. 1929. Pp. 246. Frs. 32.

IN his introduction, Dr. André Thomas seeks to provide the reader with a definition of "repercussion" or "repercussivity" and with a general exposition of his point of view. When in the bodily organism a given organ is affected it reacts on other healthy mechanisms—this is known as "sympathy," or sympathetic action. But when the physiological activity of other viscera reacts on the affected organ, the phenomena are considered to be different, and the suggestion is that the process should be distinguished as one of "repercussion," and the condition, "repercussivity." For example, the pilomotor reflex can be elicited in the normal subject by simple cutaneous excitation—for the upper limb, by excitation in cervical or axillary regions. Now if the arm has been wounded, with evident skin cicatrisation (peripheral nerves need not have been involved) the reflex appears more rapidly, is of greater intensity, and lasts longer on the affected than on the healthy limb. In other words, a change has taken place whereby the local or regional susceptibility of the skin has increased, and this is regarded as an instance of repercussivity. The abnormal reacts to the normal in an exaggerated way; the resistance of the pilomotor mechanism to stimulation has been reduced, the threshold lowered. Dr. Thomas then proceeds to apply this discovery to a number of differing conditions in which a given part of the organism is already affected, taking for a further example sudoral activity. He finds that in the vicinity of wounds (say in arm or neighbouring region of thorax), homolateral hyperidrosis occurs with some regularity, and he notes the same in respect of vasomotor repercussivity. Proceeding in an ingenious if rather speculative fashion, he next argues that some of the symptoms of the epilepsies can be explained on the supposition that stimuli otherwise inert or minimal produce their effect precisely because of an increased susceptibility—that is, repercussivity—the result of some existing abnormality; similar reasoning is applied to those of migraine, asthma and angina pectoris.

On the whole, this book provides stimulating reading, unwise though it may be to generalise hastily from the relatively restricted basis of observed facts.

THE LANCET.

LONDON: SATURDAY, SEPTEMBER 7, 1929

VITAL STATISTICS OF 1928.

THE first of the three parts, in which the annual vital statistics of this country are now presented by the Registrar-General, contains a wealth of detailed information of which only the salient features emerge on cursory perusal. Much interest attaches to the growth and changes in the age-constitution of the population of England and Wales, and, although not contained in the volume at present under review, this information is already available, and its direct bearing on questions of morbidity and mortality makes it essential to emphasise certain fundamental points. The population of this country, the estimated total of which for 1928 is 39,482,000 persons, has of recent years been undergoing changes in composition which profoundly influence the total annual quota of deaths. The declining birth-and death-rates have resulted in a diminution in the proportion of infants and young children, and a corresponding rise in that of persons in the later life. For instance, the figures contained in the last two censuses show that in 1911 the population aged 0-5 years, and 55 years and over, formed respectively 10·7 and 11·6 per cent. of the total, whereas within the succeeding decennium the proportion of young children had fallen to 8·8, and the 55-years-and-over group had increased to 13·7 per cent. For 1928 the corresponding figures work out at 8·1 and 15·8 respectively. Obviously, the effect of such a change on crude mortality-rates will be unfavourable because of the larger proportion of persons now living at ages subject naturally to heavy rates of mortality, and this emphasises the need for some method of "standardisation" when long-time secular changes in the death-rate are under consideration. The total deaths registered in the past year (460,389) correspond to a crude rate of 11·7 per 1000 population, compared with 12·3 in 1927. With two exceptions this is the lowest rate ever recorded. When the influence of the changes in age distribution is eliminated (as far as can be done by a statistical process) the "standardised" death-rate is reduced to 9·9 per 1000 living, the lowest ever recorded since the beginning of registration. Compared with the previous year, 1928 must therefore be regarded on the whole as exceptionally healthy, the improvement being however practically confined to childhood and ages over 45 years.

Analysis of the separate causes of death shows that the chief contributors, in descending order of importance, are: disease of the heart and circulation, which recently have shown a tendency to increase, respiratory diseases (all forms) from which, possibly owing to the mildness of the winter, mortality in 1928 was abnormally low, malignant disease, diseases of the nervous system, and tuberculosis. The relative frequency of the several important cause-groups is substantially similar to that of the previous year. The deaths registered from tuberculosis, both respiratory and other forms (29,709 and 6824 respectively) are in each case the most favourable returns since the end of the war, which marked the commencement of what since then has been an almost uninterrupted decline. Deaths from cancer again show an increase, the total number, 56,253, being equivalent to a rate of 1425 per million persons living. The distribution of mortality by site affected shows a fairly close correspondence with that shown in the statistics of immediately preceding years. Although relatively unimportant causes of mortality, diabetes and, this year more particularly pernicious anæmia, possess for the clinician a special interest. Mortality from diabetes shows an increase over that recorded in the previous year, but here, as in other years since the introduction of treatment by insulin, the increase is confined to the later ages of life. The introduction during 1927 of liver treatment for pernicious anæmia has coincided with a reduction in the number of deaths from 2655 in 1927 to 2130 in 1928, the crude annual death-rates per million for each of the years of the triennium 1926-8 being 71, 68, and 47 respectively. More careful analysis is obviously required before causal connexion is established between the introduction of a new therapeutic remedy and an improvement in mortality, but the figures at least must be regarded as exceptionally encouraging. Among epidemic infectious diseases, we note in 1928 the continued though slightly diminished prevalence of small-pox, an increase in the incidence of scarlet fever, diphtheria, and erysipelas, a decline in the number of deaths from whooping-cough and influenza (the recent epidemic was just beginning towards the end of the year), and in the notifications of acute poliomyelitis and encephalitis lethargica.

The number of children born in 1928 was 660,267, an increase of some 6000 births over the previous year. This is, apart from 1927, the lowest birth-rate on record. The decline in fertility has its influence on the risk of death to infant and mother. A falling birth-rate is generally associated with an increasing proportion of first births and a decreasing frequency of infants born into large-sized families. Recent statistics have shown how great is the loss of life in these large families compared with that experienced in small families, and although first-born infants fare slightly worse in respect of mortality than do second or third-born, their chance of living through the dangers of the first year of life is, on the average, bright compared with that of infants born into families of more than three. Thus the declining birth-rate leads to a parity distribution of infants increasingly favourable to a low recorded rate of mortality. How much of the improvement in the loss of infant life which has taken place since the beginning of the present century may be due to this circumstance and how much to intentional efforts of control, to which it is more generally attributed, has not yet been thoroughly investigated. Maternal mortality has an opposite tendency. The increasing proportion of first-births with its attendant enhanced dangers to the mother (more especially in certain diseases such as eclampsia) may offer a partial explanation at least of the lack of amelioration in this mortality-rate. The deaths of infants under one year of age show a decline from 70 per 1000 births in the preceding year, to 65 in 1928, the major part of the improvement being attributable to the fall in bronchitis and pneumonia. We note also the continued high level of deaths from injury at birth and congenital malformations; and that, in general, the decline is in the main in the latter half of the first year of life. The inclusion of a table showing for the

separate sanitary areas the number of stillbirths by sex and legitimacy—the only difference in substance and form of presentation of this from previous reports—offers to workers in the field of maternity and child welfare data of a most valuable nature. County boroughs and other urban districts show, in the aggregate, the highest rates, rural districts occupy an intermediate position, and London has the most favourable experience. Geographically, the order in respect of antenatal mortality of the separate areas is, from highest to lowest: Wales, Northern Counties, Midlands and South (including London). Males experience a stillbirth mortality 16 per cent. in excess of female, and illegitimate show a rate 40 per cent. in excess of legitimate infants. The need for careful study of the factors which operate to produce such wide divergencies is obvious. The record of mortality among child-bearing women offers little scope for optimism; indeed the experience of the year under review is the worst on record since 1911. There were 2920 maternal deaths (a rate of 4·42 per 1000 live births) compared with 2690 in 1927, the increase being found chiefly in the three cause groups, accidents of childbirth, puerperal sepsis, and puerperal albuminuria and convulsions. Although, as we have seen, there are certain changes occurring in the reproductive section of the female population tending towards an increase in the death-rate, we might reasonably have hoped for better results, and are forced to admit how urgent is the need for further efforts towards a diminution in a section of mortality generally considered to be pre-eminently avoidable.

The value of these reports to research and public health workers generally has often been stressed, but too few of them, we fear, yet avail themselves of the manifold opportunities for research into the pressing problems of the day which these admirable collections of data offer.

THE COMPLICATIONS OF VACCINIA.

A SERIES of cases of encephalitis following vaccination which, although few in number, are by their nature distressing, have stimulated the interest and concern of both the public and the medical profession. That vaccination is a procedure of necessity, attended by sequelæ which, in rare instances, are severe or even fatal, has never been denied; the study of the clinical aspects of vaccinia by T. D. ACLAND in Allbutt and Rolleston's System of Medicine, remains the classical presentation of the case. The medical profession as a body, and the educated public to a large degree, have always preserved a sense of proportion, and have weighed in the balance the exceptional disadvantages and the universal advantages. While this remains true to-day, it is yet highly essential that questions of technique, both in the process of vaccination and in the preparation of the lymph, should be reviewed in the light of accumulated experience. A virus originally procured from a lesion in a cow may, to-day, be propagated in a number of different ways, such as by passage through rabbits, and by culture in association with tissues. These modifications are not the technique of JENNER; and our knowledge of "filter-passing viruses" is still so rudimentary that a strict watch must be kept for any evidence of change of type or virulence. Until recently, the gravest dangers of vaccination have been regarded as those of sepsis, common to all skin lesions, and largely avoidable. We have, however, to visualise to-day the possibility—for it is certainly no more—of lesions in organs other than the skin, and in particular, in the central nervous system.

Material is too scanty as yet for legitimately dogmatic inferences in the human subject. But, in the work of Prof. J. C. G. LEDINGHAM and Dr. MARY BARRATT, published on p. 515 of our present issue, we have definite evidence that, in the rabbit, two strains of the vaccinia virus, when applied by scarification of the skin, led to death with visceral involvement in certain cases. It has in the past been suggested that such deaths are due to excitation of a latent infection with a practically universal bacillus of the food-poisoning group—a bacillus which frequently decimates animal houses. The work of Prof. LEDINGHAM and his colleague completely disproves this assumption on histological and bacteriological grounds. Lesions of the type described may be produced in rabbits either by the intravenous injection of the normal cutaneous virus, which is in everyday use in the human subject (though never injected intravenously) or by scarification of the skin by certain modified viruses which, in this country, are not in use. And, as the authors point out, this work clearly shows that they must not be used. It is to be noted that encephalitis was not a feature in any of the affected rabbits, which suffered rather from generalised vaccinia. Such generalisation is a rare occurrence, usually not fatal, in man, and is not associated with encephalitis. The strains of vaccinia virus available are very numerous. Originally they were propagated by serial scarification of calves, or by using the material from one human case to infect another. Early in the present century rabbits were used as intermediates between one calf and another. Still more recently LEVADITI prepared his neurovaccinial virus by injecting the skin virus into the brain of rabbits. He claimed thereby to have "fixed" the virus, so as to make it affect the brains of subsequent rabbits; this has not been confirmed. But his neurovaccinial virus has been propagated in the testes of rabbits and used extensively in Spain on human cases without, apparently, any disadvantages following; as noted in this paper, it is stated to have led to encephalitis in Holland when similarly used.

There seems to be no evidence whatever that any additional encephalitic virus has been picked up from rabbits, which never suffer from this type of encephalitis spontaneously. But propagation in the brain and testes of rabbits is shown to alter the virus, not in the direction of the production of encephalitis, but in the direction of dissemination of the virus, rather than localisation in the skin when applied by scarification. The immediate bearing of this work on post-vaccinial encephalitis is not, therefore, direct. It is clearly proven that there is a choice of material, and that some material is to be discarded. It is suggested that a modification in the properties of vaccine lymph may be induced by the technical methods employed. That is a great advance. It should be more simple, in the future, to carry this process of analysis further, and to determine whether any grounds at all exist for the belief that the vaccinia virus may be modified so as to lead, however rarely, to encephalitis. The practical aspects of this question should not however blind us to the important theoretical issues involved. Few problems of infection have remained so obstinately elusive as that of the "filter-passer"—a name quite inappropriate to the virus of vaccinia at any rate. Its study in tissue culture, and by propagation in the rabbits' testes, open new avenues. Its modification with modified technique may throw new light on its properties. And every new fact ascertained with regard to it serves as a guide to analogous investigations into the nature of other diseases of analogous origin. Perhaps, in the widest interest of humanity, it is this aspect of the study of vaccinia which we should welcome, rather than the light it throws on the clinical accident known as post-vaccinial encephalitis.

OPEN-AIR BATHING FACILITIES.

THE return of the heat-wave brought a reminder of the disabilities suffered by Londoners who have few opportunities to get rid of their surplus heat in semitropical weather. The sufferers will gladly learn of the plans in the mind of the new Commissioner of Works. Mr. LANSBURY is providing seats in Trafalgar-square and a playing space for children around the Albert Memorial in Hyde Park. He proposes further outdoor shelter for children in Bushey Park and is opening to the public the Cambridge enclosure at the Admiralty Arch. In all the public parks the policy is to be carried out of taking down the railings where they are not required to protect natural beauties. But all this leaves untouched the great desire of all children and most healthy adults to bathe in the open air during a hot spell of weather, and not only to bathe but to have the opportunity of sitting about in undress both before and after the dip; and the proposal to make the Serpentine available for this purpose will be welcomed. Holiday visitors to the continent this year must have been struck by the prodigious increase in the facilities for open-air bathing provided wherever a lake or a bathing pool of any size is available. The capital outlay is small and the running cost is covered by the modest fee paid by the throngs of people of all ages who find refreshment and vigour from bathing in a judicious mixture of sun, air, and water. At the present time the Serpentine is of little, if any, use to women bathers since no provision has been made for dressing and undressing. Their need may be the less urgent since one of the most striking features of the emancipation of women in all civilised countries is the comparative freedom with which her clothing transmits air and sunshine; there has been no effective corresponding movement to secure similar skin culture for the male population. But happily the problem of providing open-air swimming facilities need no longer be complicated by sex differentiation. Honest fears of the harmful effects of mixed bathing have long been set aside by experience, and there is now no possible excuse for refusing the facilities on any such grounds. Indeed, it is refreshing to see how the newer generation accepts, without thought of evil, behaviour that those of maturer years once feared as threatening inviolable principles. A little healthy humiliation may result to the elders from the comments and puzzled questioning of young people on hearing descriptions of ladies in voluminous garments, emerging from discreetly hooded bathing machines and bobbing in the shallow water as they clung to the end of a rope, whilst in a remote part, to which none of them would dare approach, the males carried out more daring feats; for not only the garments but the other restrictions of those days made women swimmers rare among those whose visits to the seaside were an annual event. By insistence upon sex these elaborate taboos, with their opportunities for more or less indecent jest and allusion, cultivated, or perhaps indicated, the Peeping Tom state of mind. If we apply the standard of "evil to him who evil thinks" we must congratulate the present generation, for in the less populous seaside places anyone once familiar with the old régime must be impressed by the way young people of both sexes, in the absence of formal rules, regulate their undressing and dressing without offence and without self-consciousness. The healthy human figure is beautiful, and the student of human nature may wonder how it came to be associated with those taboos from which we are now freeing ourselves with benefit to health and happiness and with no detriment to our morals. If he lives long enough he may learn, for the history of fashion either in clothes and habits of thought gives little support to the idea that the sensible conventions now adopted will remain stationary. They will inevitably change—whether in the direction of what we would now call greater licence or in that of greater prudery. In either case we do not anticipate that any obstacles will be placed in the way of mixed bathing in our time. The plans of the Commissioner of Works accord with the trend of the times, and it is to be hoped that they will take some practical form before the summer comes to an end.

Annotations.

"Ne quid nimis."

THE INTERNATIONAL CONGRESS OF OPHTHALMOLOGY.

THE Ophthalmological Congress which was opened by the Queen Mother of Holland at Amsterdam on Thursday afternoon resumes the long series of international gatherings which have twice been broken by wars in Europe since the first meeting at Brussels in 1857, when the ophthalmoscope was newly discovered and pioneers like von Graefe and Donders gave the fruits of their experience. The fourth meeting appointed for 1871 in Berlin was prevented by the Franco-German War, and the twelfth planned to take place at Petrograd in 1914 was not held, although the communications prepared for it were circulated to members. The present Congress is guided by the rules and by-laws drawn up by a committee under the chairmanship of Mr. Treacher Collins which met in conference at Scheveningen in 1927. Papers printed beforehand include reports on visual standards, standardisation of perimetry, of visual acuity, of the notation of the meridians of astigmatism, and on the light-sense test, on uniformity in the programme of teaching ophthalmology for medical students and future ophthalmologists, and on unification of the standards for airmen, motor drivers, railwaymen, and sailors. A directory has been brought out of all practising ophthalmic surgeons in the world, of all ophthalmological societies, institutes, hospitals, and asylums for the blind, and of ophthalmic journals. This alone makes a volume of over 350 pages, of great value for reference purposes. The list of papers to be read at the present Congress includes 232 items, each of which is abstracted in five languages—English, French, German, Italian, and Spanish. The programme obviously covers a wide range of subjects, many of them of international interest, and the promoters are to be congratulated on the achievement of a Congress which is likely to be a new landmark in the science and practice of ophthalmology. The gathering should not only advance knowledge but engender a spirit of mutual respect and esteem among the participants. Besides the devoted work of Mr. Collins the arrangements, as far as they concern the English-speaking world, owe much to the labours of Sir John Parsons, Mr. Leslie Paton, and Dr. de Schweinitz, of Philadelphia.

THE PATHOLOGY OF TRYPANOSOMIASIS.

TRYPANOSOMES are harmful in many ways. Within the vessels their mere presence and multiplication may block capillaries and do mechanical damage; during their life or after their death they may form toxins causing perivascular inflammation. In the serous cavities they may multiply and cause irritation, giving rise, e.g., to pericarditis; invading the tissues they may set up inflammation and degeneration. The presence of trypanosomes in the tissues after death is not often reported. P. Regendanz and R. Hoeppli of the Hamburg Tropical Medicine School, who have just published[1] the outcome of their prolonged investigations, believe it to be because autopsy is delayed too long, for the parasites are altered by post mortem changes more quickly in the tissues than in the vessels. The flagella disappear first, then the protoplasm assumes a rounded shape and loses its special staining affinities; the blepharoplast and nucleus persist longer, but are apt to be mistaken for bacteria unless examined under a high power, when their irregular edge and lighter central staining distinguishes them. Subjects of trypanosomiasis are apt to suffer from peri- and myo-carditis with dilatation; is the infection brought by the blood stream? The Hamburg investigators think not, but due rather to an extension from the pericardium within which the trypanosomes are growing; morbid changes are more advanced in the epicardium than in the heart, and in the superficial layers of the myocardium than in the deeper. The first histological evidence of trypanosome infection is an œdema which may be due to toxins, though such toxins have not yet been isolated. Into this œdematous area the trypanosomes having penetrated, they increase, setting up a small-cell infiltration similar to but less in degree than that of bacterial inflammation; the muscle cells degenerate later. Trypanosomes, living and moving, may be found in plenty in the fluids of serous cavities and in that of the conjunctival sac, even when they are but scantily present in the blood. Conjunctivitis is not unusual in trypanosome-infected animals; iritis and keratitis also occur, and living trypanosomes have been found in the anterior chamber. Thence they make their way along the lymph stream into the subconjunctival connective tissue, causing œdema and inflammation, and so reach the conjunctival sac, where they are most numerous about the fornix. This sequence of events was first observed with *T. equiperdum*, although most of the work was done with *T. gambiense* and *T. rhodiense*, of which the latter gives rise to the more acute infection in apes. Whether the growth of trypanosomes in serous cavities accounts for relapses will be discussed in a subsequent paper.

MINIMAL DOSES OF HEAVY METALS.

DR. Guiseppe Sabatini, professor of special pathology in the University of Rome, has been investigating[1] the effect of injecting into the circulation extremely small quantities of salts of the oligo-dynamic metals, such as copper, zinc, and mercury. The vogue of the infinitely small, he remarks, is continually extending its influence in biology, and even in clinical medicine. He has been impressed by the demonstrations of "ultravirus," of aphanozoa, of fatal anaphylaxis produced by minute doses of serum, of the powerful effects of imponderable amounts of hormones, and of the posology in fractions of a decimilligramme of pure alkaloids. In Italy there has been a tendency to reconsider the doses of commonly used drugs, and claims have arisen for remarkable effects from doses conspicuously smaller than those generally employed in therapeutics. It may easily be predicted that the edifice of necessary and sufficient therapeutic doses fixed by scientific medicine is not really on the verge of collapse, but according to Prof. Sabatini we should be guilty of stupidity to ignore such investigations altogether. His own experiments were inspired by the observations of A. van Egmond on the action of certain drugs on the bundle of His, and on the production of heart-block by the action of oligo-dynamic metals. This author showed that simple contact of the bundle of His with a copper wire 2 mm. in diameter caused heart-block. Having excluded the possibility of thermic effect, pressure, and galvanic current, he concluded that it was due to an infinitesimal chemical action on the cells in the bundle. In the same field of observation, Stock, in 1926, maintained the possibility of mercurial intoxication in man caused by the amalgam used in stopping carious teeth, and Seifert, examining several hundreds of syphilitic patients belonging to every social grade, noticed that about 80 per cent. of them had no teeth filled with metallic stopping, while in a series of patients with many filled teeth syphilis was much less prevalent than in others, and he suggests that the minute doses of mercury absorbed by the organism in these subjects may act as a prophylactic. The researches carried out by Prof. Sabatini fall into five groups: (1) chloride of copper, one milligramme dissolved in 2 c.cm. of distilled water; (2) chloride of zinc, in the same proportion; (3) bichloride of mercury, in the same proportion; (4) bichloride of mercury, half that strength; and (5) controls consisting of injections of 2 c.cm. distilled water only. These quantities were injected into a vein and samples of blood taken after 1 hour, 8 hours, and 24 hours. These samples were examined as to the number of red cells, the number of leucocytes, the leucocytic formula, and for glycæmia. The specimens showed very definite changes, the number of red cells and leucocytes being distinctly, and sometimes conspicuously, increased, while the glycæmic content was raised to about double the normal. The changes were transitory and a return to the previous condition took place after 24 hours. Dr. Sabatini is continuing his investigations especially with other salts.

RESEARCH IN TUBERCULOSIS.

Two years ago the Prudential Assurance Company provided a new pathological department for the City of London Hospital at Victoria Park, and the report for 1928, recently issued, testifies very clearly to the value of this benefaction. The laboratory has examined nearly 10,000 specimens from the wards and outpatients during the year, and the report includes also reprints of four papers published by Dr. S. Roodhouse Gloyne and his assistants. The chief one is a useful review by Dr. Gloyne of the clinical pathology and bacteriology of fluids obtained by tapping the pleura. With Dr. J. R. Simpson he has also attempted, and failed, to produce tuberculous meningitis in rabbits. It is curious that generalised infections produced by intravenous injections in these animals hardly ever involve the meninges, and it is suggested that this is so because the bacilli do not lodge in the cerebral vessels; tuberculous meningitis is perhaps always preceded by lesions in the choroid plexuses. Lesser papers deal with the viability of tubercle bacillus at freezing temperature and with the relationship between syphilis and tuberculosis which seems to be very small. The whole report indicates a lively response to the help given by the Prudential Company and augurs well for the extension and expansion of activity which future years will doubtless show.

LUNATICS AS A PUBLIC DANGER.

Lord Alness, the Lord Justice-Clerk, has been commenting in the Glasgow High Court upon the danger to the community from the freedom allowed to persons of unstable mind. In the case to which our Scottish correspondent draws attention on p. 525 a man had been proved to be of unsound mind and unfit to plead. He was also described in the evidence as being in the same mental condition when released some time earlier from a mental institution. While thus at large he had shot a young woman dead and had attempted to shoot a man. The Lord Justice-Clerk, while refraining from attributing blame to individuals, suggested that the general position was disquieting and that the authorities should inquire whether some machinery could not be devised to prevent the recurrence of such deplorable incidents. Similar comments might at any time be made in England where full investigation has been officially made without any attempt to give effect to the resultant conclusions. Royal Commissions may make recommendations but, until some prominent personage is killed by a lunatic, it may be difficult to translate those recommendations into law. More than one judge has warned the public in England of the consequence of exposing members of the medical profession to the risk of huge and capricious awards of damages for alleged negligence. When a jury gives a verdict of this nature, medical practitioners are scarcely encouraged to sign the certificates which are the statutory preliminary to a magisterial order for the detention of a lunatic in a suitable institution for treatment.

---

[1] Policlinico, Medical Section, June 1st, 1929, p. 281.

There is an allied question whether issues involving an exact estimate of medical skill are best determined by juries consisting entirely of laymen. In this connexion a correspondent in the daily press has lately been giving an interesting illustration. He describes his experiences as foreman of a jury at a trial at the Old Bailey in a case involving charges of fraudulent income-tax returns. The nature of the issues involved frequent references to columns of statistics and complicated figures and calculations. A woman member of the jury said to him at one point, "I do not know what they are all talking about: this is not a case that women should be asked to try, do you think?" So frank a confession by a layman faced with technical issues is significant. The correspondent remarks upon the incongruity of expecting persons who have had no financial training to adjudicate upon facts in which complicated figures form the material. How is it any more reasonable to expect 12 laymen to adjudicate upon complicated issues of medical diagnosis and treatment?

THE TASTE OF CHLORINATED WATER.

It is well known that although one part of free halogen in a million of water will render drinking water sterile, yet the taste produced is offensive to most people. As this taste resembles that of iodoform and is not like that which would be produced by free chlorine itself, its investigation is a matter of considerable interest, both on theoretical and practical grounds. In the *Medical Officer* of August 17th Mr. B. A. Adams describes some work done by him which seems to show conclusively that the taste is to be attributed to the action of chlorine on salicylic acid or some of its derivatives extracted from the leaves or twigs of certain willows and waterside plants, such as the meadow-sweet (*Spirea ulmaria*). Mr. Adams points out that although it is usual to attribute the development of taste to phenolic bodies, it appears that only those which are associated with coal-tar products will produce the taste, and in some cases these have been shown not to be present. The phenols found in vegetable and animal substances do not appear to yield the taste, but natural salicylic acid (which cannot be suspected of containing even traces of phenol) will give a faint taste when present to the extent of only one part in a hundred millions of water if treated with 0·25 part of chlorine, as will sodium salicylate, phenyl salicylate, salicylaldehyde, and salicyl alcohol. On the other hand, salicin, methyl salicylate, acetyl salicylic acid and coumarin do not give the taste in any concentration examined. As salicin, which is an easily hydrolysed glucoside, occurs in large quantities, together with its appropriate hydrolytic enzyme, in many willows and poplars as well as in meadow-sweet, all of which are, along with other salicyl compounds, typical waterside plants, Adams experimented with this and with other natural salicyl compounds. He found that infusions of willows (*Salix fragilis* and *alba*), poplars (*Populus tremula, candescens, alba, nigra, deltoida, italica*), and meadow-sweet are all capable of producing an iodoform taste on chlorination, whilst the sallows do not invariably give the taste, and a large variety of other trees do not do so. The taste tends to be prevalent in autumn when there is a great fall of leaves and small twigs into the water, by which willows and meadow-sweet grow. It is easy, therefore, to see that an appreciable amount of salicyl compounds may thus pass into solution, and when the water, which is likely at this time to need chlorination more than at any other time, is so treated the taste is developed. A remarkable point brought to light in this research is the non-formation of taste when ammonium salicylate is chlorinated, a fact which throws some light on the use of ammonia in removing the taste from chlorinated water. Direct proof of the presence of salicylic acid or its derivatives in the water of any river or other natural water would be very difficult. The American workers who investigated the organic matter of lakes found it necessary to evaporate hundreds or thousands of litres of water in order to obtain enough to examine. Besides this it by no means follows that evaporation will leave all the organic matter behind. We feel, however, that Mr. Adams has sufficiently maintained his thesis, more especially as his experiments were made with well water, which may be considered as originally free from either salicyl compounds or their chloro-derivatives.

INSTITUTES OF RADIOLOGY.

The twelfth volume of the series called "Methods and Problems of Medical Education," issued by the Rockefeller Foundation, is concerned with rontgenology and radiation work in general. Beautifully printed and lavishly illustrated it describes 30 installations in different parts of the world, five of them in Britain—Edinburgh, Liverpool, Manchester, Cancer Hospital, and Guy's. Despite the general title this volume will be of less interest to teachers than to those engaged in the therapeutic and diagnostic applications of radiations. For these it will be particularly useful, because the technical details of the arrangements are really important, and not, as is often the case, matters of preference or prejudice. Especially informative is Dr. A. E. Barclay's description of the X ray department which he organised at the Royal Infirmary in Manchester, for he gives careful and detailed lists of the equipment and personnel, with their cost, which are needed for hospitals of different sizes and varying characters, and discusses many of the problems of construction and arrangement with much informative detail. The account of the Finsen Institute in Copenhagen is also conspicuous and gives us a pleasing photograph of Finsen's statue in the grounds. Careful study of books such as this should do something to correct the parochial experience which our in-bred hospitals too often show.

PREVENTING DIPHTHERIA IN NEW YORK.

It is now on record that in certain districts in America diphtheria has been almost entirely eliminated as a result of immunising all children with toxin-antitoxin. In Auburn, for example, the death-rate from diphtheria has been reduced from 38·4 to zero, while New York State, which began a campaign three years ago, has a mortality and morbidity rate considerably lower than New York City. On another page we comment on a collection of studies from the laboratories of the health department of New York City which show the overwhelming evidence now available of the value of therapeutic immunisation. These considerations, coupled with the fact that in New York City there were last year over 10,000 cases of diphtheria with 912 deaths, led to the formation of a "Diphtheria Prevention Commission," under the presidency of Mr. Thomas W. Lamont, which launched a campaign early this year. The methods employed in this campaign and some of the early results are recorded in a handbook, entitled "How to Protect your Children from Diphtheria," which has been prepared under the supervision of Dr. Shirley W. Wynne, commissioner of health for the City of New York, and edited by Mr. E. Fisher Brown. Mr. Lamont gave an address to the editors of the various city newspapers at the Harvard Club in January, and leading articles appeared in the more important journals during the following week indicating the scope of the campaign. Some of these are reproduced in the handbook. The Health Department wrote to 11,315 practising physicians asking them to circularise their patients with notices prepared by the department urging immunisation, and it was arranged to approach 150,000 families for a test demonstration with the coöperation of five medical societies. Toxin-antitoxin is prepared by the Health Department and is available at 750 pharmacies where physicians can at any time obtain what supplies they may need in their private practice. At the same time 44 stations have been opened in various parts of the city where free immunisation treatment can be given. Dr. Wynne is quite clear as to the exact part which the private practitioner and the public health official have to play in the campaign. At the inaugural luncheon he said:

> The public owes the medical profession a more liberal attitude in the matter of fees. The public must learn to pay for preventive medicine as ungrudgingly as it pays periodically for its theatre tickets and moving-picture shows. I am not willing that the Department of Health be the official doctor, nurse, clinic, and hospital regardless of the ability of the individual citizen to pay the doctor for such a service. Nor is the department prepared to undertake all these services. We are, however, willing and prepared to immunise every unprotected child where its parents for any reason are unable to pay for the same.

Ten years ago the Schick test and toxin-antitoxin immunisation were introduced into the municipal schools in New York, and in examining the results it is estimated by Dr. William H. Park that the amount of diphtheria reported among those receiving immunising injections was only a fifth of that among those not injected. Out of 500,000 immunised not a single patient suffered any ill-effects. These results are excellent, particularly when it is remembered that of all children receiving toxin-antitoxin probably only 80 per cent. are definitely immunised, but it is desirable to extend the protection to all children between the ages of 1 and 9, estimated at 750,000, in the city of New York. It is with this object that the new campaign has been started, and already in March it was possible to state that there had been since the beginning of the year a decrease of more than 30 per cent. in the diphtheria rate and in the death-rate. With close coöperation between public health authorities, parents, and doctors, it is hoped to eliminate the scourge of diphtheria from the city where Dr. Park originated his method of protection.

APPENDICITIS IN PREGNANCY.

SINCE a large percentage of pregnant women complain of abdominal pain, vomiting and other symptoms which disappear either during or after the pregnancy, cases of acute abdominal disease occurring in pregnancy may be masked. A. L. McDonald in a recent paper[1] compares a large series of cases of appendicitis in pregnant with another series in non-pregnant women. Apart from difficulties in diagnosis pregnancy increases the dangers of the disease. As the uterus rises in the abdomen, the cæcum tends to be less protected. The omentum is generally to be found resting on the uterus, far removed from its normal situation in close relation to the intestines, and some authorities state that the uterus as it rises pulls the cæcum away from the less absorbent pelvic peritoneum. General peritonitis is therefore on theoretical grounds more likely to follow perforation of the appendix during pregnancy, and local abscesses to be less frequent. Dr. McDonald's statistics support this view. The series he has used as a control is that collected by E. P. Quain, consisting of 1000 cases, and he has compared with these a series of 204 cases occurring in pregnant women, studied by E. Jerlov, and a group of 70 investigated by himself. The control series show general peritonitis in 16 per cent., and localised abscesses in 29 per cent. In the pregnant patients—a much smaller group—these figures are exactly reversed, namely, general peritonitis in 29 per cent., and a localised abscess in 16 per cent. The mortality of appendicitis complicated by general peritonitis, which is 11 per cent. in Quain's cases, rises to 30 per cent. in the group of pregnant women, while the mortality with a localised abscess rises from 2.4 per cent. to 23.5 per cent in pregnant women. The lesson of the investigation is that delay in the diagnosis of appendicitis is even more dangerous during pregnancy than at other times, and that every effort should be made to operate on cases of appendicitis during pregnancy before the infection passes beyond the appendix. The mortality is greater when the patient aborts or goes into premature labour; the author notes, however, that the onset of labour depends largely on the severity of the toxæmia. Many cases do not die because they abort, but abort because they are dying. Pregnancy does not in any way modify the surgical treatment of acute appendicitis. Every effort must be made to prevent the onset of labour; if delivery is inevitable, it should, if possible, be vaginal and not abdominal.

TWENTY YEARS' EXPERIENCE AT A FEVER HOSPITAL.

THE special characteristic of the study of scarlet fever, diphtheria, and enteric fever, recently published by the Medical Research Council,[1] is that one observer, Dr. E. W. Goodall, was responsible for the clinical work throughout the period under survey. The statistics, which refer to more than 21,000 cases of scarlet fever, 15,000 cases of diphtheria, and 2000 cases of enteric fever, have, therefore, a peculiar value, since those already available in the Annual Reports of the Metropolitan Asylums Board and elsewhere have been compiled from several hospitals, and conclusions drawn from their study may have been vitiated by variations in standards of classification. Tables are given here showing for each disease the age distribution, the variations from year to year, the seasonal distribution, and the age and seasonal incidence of complications, also the relation of complications to form of disease, and the fatality. The statistics here presented do not show any relation of school closure during the summer holidays to the incidence of scarlet fever, though in diphtheria a diminution was found. Since a reduction of scarlet fever cases is found almost every year for the holiday period in the notification statistics for London as a whole its existence cannot be doubted. The statistics for the whole of London certainly contain a moderate percentage of erroneous diagnoses which have been eliminated from the figures supplied by Dr. Goodall, but the diminution is too great to be attributed to this cause. Another discrepancy between the two sets of figures concerns seasonal variations at different ages. A table in the study just published shows a marked difference of seasonal variation between the first and second decades in scarlet fever, though in diphtheria there was little change. The charts published in the M.A.B. reports indicate that the seasonal variation is always largest in epidemic years, and may be quite absent in years of low prevalence, like 1903 and 1910. The large epidemics of 1907 and 1914 must be considered in relation to the figures presented. The tables dealing with form of disease, complications, and fatality mostly break new ground. The characteristic autumn rise in scarlet fever is shown to be almost entirely due to the mild cases; the distribution of septic cases throughout the year shows no regular trend. Among scarlet fever complications albuminuria is rather more frequent in late summer, but otitis, nephritis, and adenitis more so in the first half of the year. Otitis is much more frequent in infancy, and the incidence regularly decreases with age, both in scarlet fever and diphtheria. Albuminuria and adenitis follow the same course, but the differences are less marked. Nephritis is less common under 4 and over 20 than at intermediate ages. All complications, except relapse and secondary tonsillitis, are much commoner after septic than after mild scarlet fever. With one or two exceptions complications were less frequent in the quinquennium 1910–1914 than between 1895 and 1899; but the intervening periods show higher rates than either. In diphtheria, laryngeal and rhinorrhœal forms occur more frequently in young children. At ages over 25 years 98 per cent. of the cases are faucial. Albuminuria shows a maximum age incidence at 6 years, and paralysis at 9 years. Otitis is most frequent in infancy. As with scarlet fever, complication-rates are somewhat lower in the last quinquennium. In enteric fever complications become more common as age advances and were higher for females than males, with the exception of otitis. In all three diseases the case fatality decreased during the periods, but whereas in the first two diseases the decline was regular, in enteric fever a minimum was reached in the third quinquennium, and a rise occurred in the fourth. The authors of the report point out that data referring to patients not wholly drawn from one district, and to a period of change in the extent to which the public have resorted to institutional treatment of the diseases, cannot throw light on the real incidence of these diseases, while even the statistics of fatality must be interpreted with caution. On the other hand the expert statistical analyses of the forms and complications of the diseases here presented are of unusual value and interest.

ÆSTHETICS AND MENTAL DEFICIENCY.

IN the annual report for 1928–29 of the Metropolitan Asylums Board Dr. E. B. Sherlock criticises the current standards of diagnosis of mental deficiency. Like many other examiners he holds that too much stress is laid on the cognitive side and upon the results of the application of intelligence tests, other aspects of their psychological make-up being ignored. More important than testing is the question of guidance and training, and Dr. Sherlock makes a plea for the development of the æsthetic sentiment in mental defectives and for the cultivation of such sense of beauty as they possess, as a contribution to their happiness and the moulding of their personalities. A preliminary difficulty to be faced is the fact that the æsthetic sentiment is conditioned very largely by the stage of intellectual development; Dr. Sherlock therefore set himself to discover in what degree æsthetic sensibility is normally present in defectives. A true æsthetic sensibility is a fairly late product of development, even in the normal. Its earliest manifestations can only be some evidence of interest or pleasure in objects usually regarded as beautiful, coupled with practical attempts at reproduction or self-expression in some artistic form. It was in these two directions that Dr. Sherlock sought for evidence, taking as his subjects the defectives in Darenth Training Colony. He describes two tests of sensitivity: one, in which the child's opinion of the pleasantness or otherwise of a variety of odorous substances was required, and a second, in which he collected the pleasurable impressions of the children derived from a performance of Cinderella. As a practical test each child was required to make a drawing of a church. It may be questioned whether inferences could fairly be made from the responses to these sample tests. Dr. Sherlock does not claim that the inquiry revealed either any sensitivity or talent in defectives different in kind from that of normals, and in degree both were, on the average, below normal. As tests, then, they reveal nothing beyond what is already known. In our view no test of æsthetic sentiment is ever likely to contribute much to a diagnosis of mental deficiency, the ultimate criterion of which is social inefficiency. The cynic might point to instances of supernormal æsthetic *development accompanied by almost complete* incapacity to attend to the practical affairs of everyday life. The real value of this or any similar inquiry rests rather in the fact that it may reveal educational possibilities in individuals. Where a definite sensitivity or talent is shown, it is the duty of the educationalist to foster it. Modern educational systems are not neglecting this matter. The cultivation of the child's sense of beauty, whether in nature or art, is an integral part of education to-day, perhaps more in the elementary than in the secondary school. That mentally defective children are not without some elementary sense of beauty, in the form of appreciation of rhythm or tone, or of relations of forms and colours is well known to special school teachers. Dr. Sherlock is disposed to doubt whether the possibilities in these directions are being fully utilised and the question he has raised appears to merit further inquiry.

STANDARDS OF FITNESS IN AIRMEN.

WE do not yet know the name or even the nationality of the winner of the Schneider Cup, but we know a good deal about his physiological make-up. He will have a visual acuity of 6/6, he will be able to exercise single vision binocularly, at very near range, and to maintain binocular vision under increasing disability. His visual field will be wide and his colour sense accurate. His Eustachian tubes will be free and efficient to regulate and equalise the continual changes of atmospheric pressure. His respiratory efficiency will be high, and his chest expansion good, and his cardiovascular system equal to the maintenance of an adequate circulation under adverse conditions of strain and low oxygen pressure. In other words, he will possess the physical and physiological attributes of any good pilot as well as a neuromuscular coördination above the normal, but in addition he must have special ability of a high order. As Sir Samuel Hoare has pointed out, it is the human side of the enterprise for the Schneider Cup that is more valuable and enthralling than the actual production of a record machine. At an early stage in the development of the Royal Air Force it was found that the existing state of medical knowledge was insufficient to entitle medical officers to give trustworthy opinions on the unsuitability or otherwise of candidates for flying. It was found that men who were apparently fit in every way, some of them even noted for their athletic prowess, were unable to acquire the art of flying, or having acquired it painfully and expensively, never became safe pilots. The question really turned on the possession of peculiar aptitudes—a question to which, of course, industrial psychologists have been devoting their attention for many years in other fields; but which at once assumed an urgent practical importance when it had to be answered, and to begin with in the stress of war, concerning the profession of aviation, in which ineptitude spells calamity. Nowadays the medical tests to which the candidates for the flying services are exposed, whilst making no pretence that every candidate selected by them will turn out to be a good pilot, are definitely selective in the sense that they are directed definitely towards the ascertaining of capacity for performance in a particular field—viz., aviation.

Some of the standards exacted by the medical selectors of flying personnel for the R.A.F. may be quoted. It is not surprising that sickness in swings or trains should debar candidates from admission, or that visual acuity of high degree is insisted on. But it is noteworthy that, according to the Manual for Medical Officers of the Royal Air Force, no candidate, whatever his visual acuity, may be passed into the service who reveals a manifest hypermetropia of + 2·00 D. sph. or over. The reasons for this restriction are that (1) the continued effort to focus rays correctly on the retina is apt to induce a tonic action of the ciliary and internal recti muscles, which tends to produce errors of judgment of distance in flying; (2) loss of accommodation is liable to occur under flying conditions, leading to bad landings; and (3) quite apart from flying the hypermetropic eye is more easily fatigued by close work or glare. Lack of true ocular balance is the most common cause of bad landings. Exophorics (sufferers from external lateral deviation) tend to flatten out their aircraft too early, having judged the ground to be nearer than it is; conversely, esophorics are inclined to fly into the ground. The need for excluding those with defective visual judgment from the flying services is emphasised by the distortion of objects when seen from the air—the verticals are fore-shortened, shadows are viewed from an unfamiliar aspect, and the pilot's judgment of distance is anyhow likely to be disturbed by the unusual speed at which he is travelling. At one time, in some countries great importance was attached to the supposed "motor-sensing functions" of the vestibular apparatus, but it has been found that its reactions to rotation are not reliable indications of flying ability. The so-called otolithic functions of the semi-circular canals afford little information about position in space, which is estimated chiefly by deep muscle sensation; their integrity is nevertheless important for air work, probably for the exertion of steady, subconscious neuro-muscular control. The rotatory chair is used now not so much as a test of the vestibular apparatus but as a means of bringing out abnormal reactions such as giddiness, nausea, vertigo, or anxiety in men whose history throws some doubt on their ability to perform aerobatics. If an aeroplane is spinning, and thus out of control, the human subject must himself be fit to take the action necessary to stabilise the machine. To test this power he sits on a chair as in an aeroplane, with eyes open and directed inside the knee furthest from the direction of spin, and is then subjected to a relatively fast spin ten times in 20 seconds. In fit pilots, especially those accomplished in aerobatics, rotation has little effect on pulse-rate or arterial pressures. A rise in pulse-rate and systolic and diastolic pressure is associated with vertigo and nausea, a fall in diastolic pressure with fainting; while in anxious subjects an anticipatory rise of pulse-rate and systolic pressure before rotation may or may not be accentuated by rotation.

Broadly speaking, it may be said that the tests, of which only a few examples have been given, are directed to ascertain: (1) that the candidate possesses sound physiological control over his circulatory, respiratory, and nervous systems, on which the stresses of flying and of altitude chiefly fall; and (2) is in possession of sound perceptive faculties and of a sound effector motor organisation through which his perceptive faculties can function; the elucidation of the latter factor is sought by the aid of tests of a definitely vocational character. Much has been found out, but much still remains to find out. It might be thought that experience of this kind had no immediate bearing on general medical practice, but this is not true for any practitioner who regards every patient who comes to see him as a candidate under examination for his fitness to perform his allotted or chosen task in life. His chief concern is in the patient's capacity for such performances. The standard use of physiological and psychological (using the word in its broadest sense) tests and of medical examinations of men in apparent health, conforms with the ideals of clinical medicine set forth by Sir James Mackenzie when he started his clinical research centre at St. Andrews—namely, to discover the signs and symptoms of failing health in the pre-sickness stage.

Lieut.-Colonel A. J. H. Russell, I.M.S., has been appointed medical assessor to the Royal Commission on Labour in India and will accompany the Commission during its tour through India this winter. Colonel Russell has been Director of Public Health in Madras since 1922.

Sir John Campbell, who died at Belfast on August 31st, was senior surgeon to the Samaritan Hospital for Women and consulting surgeon to the Maternity Hospital. He figured largely in public life, being chairman of Convocation of Queen's University and representative of the University in the Northern Parliament of Ireland.

The Clinical Interpretation of Aids to Diagnosis.

A Series of Special Articles contributed by Invitation.

XLII.—SIGNIFICANCE OF THE ACID BASE BALANCE IN THE BLOOD.[1]

SOME 16 years ago, as can be readily seen from a study of the literature of the time, the disturbances of the acid-base balance in disease were subjects of controversy and vague speculation. Since then clear ideas on the subject and methods of expressing deviations from normal in figures have developed, and the vague speculations have been replaced by definite and wide accepted facts. It is necessary now to use precise terms in order to avoid vagueness. The significance of the terms in common use is explained below.

Dissociation; Meaning of cH and pH.

When dissolved in water strong acids, like most salts, dissociate completely or almost completely into ions—e.g., $HCl \rightarrow H^+ + Cl^-$. The kations (marked with a + sign) carry positive electrical charges and differ from the corresponding atoms by having given up one or more (depending on the valency) electrones, while the anions (carrying a − sign) carry negative charges and have gained one or more electrons. Weak acids, however, dissociate only partially, for example, acetic acid

$$CH_3COOH \rightleftharpoons H^+ + CH_3COO^-$$

The weaker an acid the less its dissociation into ions, and at the limit we have water which dissociates very slightly, as $H_2O \rightleftharpoons H^+ + OH^-$. Similarly bases dissociate to a degree depending on their strength—e.g., $NaOH \rightarrow Na^+ + OH^-$. The dissociation of weak acid is a reversible reaction; if the concentration of the hydrogen-ion or of the anion is increased the reaction shifts in the direction of the undissociated molecule. It is the presence of hydrogen ions in all watery solutions and the part they play in such reversible reactions that make hydrogen-ion concentrations of great importance in biochemistry.

The *hydrogen-ion concentration* (represented by the symbol cH) is expressed quite simply by the number of grammes of hydrogen present in the ionic form per litre; thus in N/100 hydrochloric acid, with 1/100 gramme of hydrogen ion per litre cH 1/100; while in N/100 acetic acid, in which only 1/78 of the acid present is dissociated, there is only 1/7800 gramme of hydrogen ion per litre (cH = 1/7800). In pure water, at 38° C., cH = 1/5,000,000.

When the hydrogen-ion concentration of a solution is the same as that of water the solution is said to be neutral; a solution with a cH greater than this is acid and one with a lower cH is alkaline. In biochemistry and medicine we have to deal with fluids with a cH near that of pure water, and to avoid cumbrous figures another method of representing hydrogen-ion concentration—pH—is used; pH = log 1/cH, or if $cH = 1/10^x$, pH = x. *Table II.* shows the pH corresponding to the cH of various fluids. When the cH increases (that is, when the solution becomes more acid) the pH decreases, and vice versa; increasing the pH of a solution by 1·0 is equivalent to dividing the cH by 10; increasing pH by 0·30 is equivalent to multiplying the cH by 2.

It is probable that the disadvantages of the general use of the expression pH outweigh the advantages, but its use is now firmly established.

Buffers.

As the range of hydrogen-ion concentration compatible with life is a narrow one, it is necessary to prevent great variation. This is done by removing excess of acid or base, but during the process, or if the removal is not complete, the effect of such excess is mitigated by the buffer systems of the body. These buffer systems consist of mixtures of weak acids with their corresponding salts; although such a mixture contains free acid its hydrogen-ion concentration may be low, since the dissociation of the *free acid is very slight in* the presence of its fully dissociated salts—it is given by the equation

---

[1] The diagnosis of acidosis, alkalosis, and ketosis will be discussed next week.

$$cH = K\frac{c(HA)}{c(NaA)}$$

where c(HA) is the concentration of free weak acid, HA c(NaA) the concentration of its salts, and K a constant for this acid (the dissociation constant). *For convenience this equation will be quoted below* as equation (1).

If a strong acid like HCl is added to such a mixture it combines with the base of the NaA forming NaCl, *and setting free HA, which is very little dissociated,* so that only a slight rise of hydrogen-ion concentration takes place. Similarly if a strong base like NaOH is added it combines with some of the free *acid and the cH is but little reduced.*

The chief buffers in the body are carbonic acid, H_2CO_3, and its salts, the bicarbonates, chiefly $NaHCO_3$, and proteins, which behave as weak acids at the reaction of the body and *form salts. When CO_2 is* retained in the body the concentration of H_2CO_3 in the body fluids is increased; part of this H_2CO_3 combines with the base of protein salts, setting free protein in the acid form (which is but slightly dissociated) and part remains as free H_2CO_3, which, however, is very slightly dissociated in the presence of its salts. Using equation (1) in its most familiar form (the Henderson-*Hasselbalch equation),* which we may call equation (2),

$$= K_{H_2CO_3}\frac{c(H_2CO_3)}{c(NaHCO_3)}$$

we can calculate the increase in cH produced by a given increase of H_2CO_3. The amount of CO_2 formed by a resting man in one minute (about 0·33 g.) would *raise the cH of 50 litres (about the volume of fluid in* the body) of distilled water to 1/40,000 (pH = 4·6); but would only change 50 litres of a solution of H_2CO_3 and $NaHCO_3$ such as is found in normal plasma, *from cH = 1/25,000,000 (pH = 7·40) to cH =* 1/23,000,000 (pH = 7·30), or 50 litres of blood, which is better buffered owing to the presence of proteins, from pH 7·400 to pH 7·397.

If an acid such as HCl is added to blood the larger part combines with the base of the protein salts, setting free protein acid, and some with the base of bicarbonates, setting free H_2CO_3. The chief buffers of blood in this way are *thus* the proteins, especially hæmoglobin, but because the free H_2CO_3 and bicarbonate can be estimated attention is mainly fixed on these two. Similarly excess of base combines with acid protein, and with free H_2CO_3.

Since equation (1) applies to proteins (P), we can write it also as equation (3).

$$= K_P\frac{c(HP)}{c(NaP)}$$

and see that the ratio of protein present in acid form to that present as salt varies with the hydrogen-ion *concentration. Herein lies one reason for the importance* of changes of cH to living organisms; the chemical state of one of their essential constituents changes proportionally to changes of cH.

Removal of Acid.

One of the chief factors controlling respiration is the cH of the blood. When this is raised or lowered the respiratory exchange is increased or decreased. Respiration thus not only removes excess CO_2 but also compensates for the effects of retention of bases or other acids. When an acid such as HCl has been retained in the body, combining with some of the bicarbonate, so that $c(NaHCO_3)$ in equation (2) is reduced and cH increased, increased respiration takes place washing out CO_2 until $c(H_2CO_3)$ is so reduced that the ratio

$$\frac{c(H_2CO_3)}{c(NaHCO_3)}$$

and hence cH are again normal. When this has occurred the ratio of protein acid to protein salt equation (3) must again be normal and, since the total amount of protein cannot have been reduced, *c(NaPr) must be restored to normal and all the* retained acid must have combined with $NaHCO_3$. When a retention of acid is thus "compensated" by washing out CO_2, the retained acid has taken base *only at the expense of the bicarbonates, and its* concentration can be estimated by the amount that the bicarbonates are reduced. The base combined as bicarbonates in the body fluid thus acts as a reserve which can be used up to neutralise retained acids, without change in the cH or utilisation of base combined with the other acids of the body fluids; it is therefore spoken of as the "*alkali reserve.*" When *excess of base is present in the blood, $c(NaHCO_3)$ in* equation (2) is raised, the cH consequently lowered, and respiration depressed.

Most organic acids are oxidised into CO_2 and water; this oxidation is so rapid that acids such as citric and tartaric when taken by the mouth cause no disturbance of the acid-base balance. Mineral acids and bases, and organic acids and bases that have escaped oxidation or other metabolic change, are removed by the kidneys. But the kidneys do not merely remove surplus amounts of any particular acid or base but also "compensate" for variations of $c(H_2CO_3)$ by excreting an acid urine, when owing to retention of CO_2 the cH of the plasma is too high; thereby they reduce the amount of fixed acid in the body fluids, and raise the amount of base available to form bicarbonates, so that $c(NaHCO_3)$ tends to be raised and the ratio

$$\frac{c(H_2CO_3)}{c(NaHCO_3)}$$

and consequently the cH tend to return to normal. Similarly when $c(H_2CO_3)$ is reduced by overbreathing, alkaline urine is passed with a consequent tendency to *a compensatory fall of $c(NaHCO_3)$.*

When an acid urine is passed a considerable part of the acid is neutralised by ammonia formed in the kidney, but ammonia plays no part in neutralising *acids in the blood and tissues.*

Disturbance of Acid-base Balance.

In disturbances of the balance of acids and bases there may be little or no disturbance of cH, nor of the buffers other than the carbonic acid-bicarbonate system, owing to the success of compensation; but there must always be a change of concentration of free carbonic acid or bicarbonate or both. The concentration of these two substances in the blood or plasma are therefore used as indices of disturbance of the balance. The concentrations of free carbonic acid and of bicarbonates are usually expressed as th number of *cubic centimetres of CO_2 gas in these tw* forms per 100 c.cm. Thus 100 c.cm. normal pla contains 55 to 65 c.cm. and 100 c.cm. of normal bl 46 to 51 c.cm. of CO_2 combined as bicarbona about 1/20th of these amounts of CO_2 as fre acid.

Disturbances of acid-base r conveniently classed in two gr primarily cause changes in the H_2CO_3; and (2) those that pr concentration of bicarbonate.

If the word "acidosis" is meaning it should be used for *type 2 (b) may* be called acetone bodies in the uri thereby avoiding confusio which the plasma bicar recognising the fact th base balance does excretion of aceto ac

In type 1 (*a*) interference with respiration owing to failure of the heart to pump blood through the lungs sufficiently rapidly or to disease of the lung would seem a likely cause of CO_2 retention, but actually, since it is much more difficult to get oxygen in than to get CO_2 out, the CO_2 is usually kept down to normal levels in the efforts to take in sufficient oxygen.

TABLE I.—*Types of Disturbance of Acid-base Balance*·

1. *Affecting c(H_2CO_3).*	2. *Affecting c($NaHCO_3$).*
(*a*) *Increase.*—Increased formation—violent exercise. Impaired elimination. Depression of respiratory centre by narcotics, and sleep. Interference with respiration (disease of heart or lungs). Breathing CO_2. (*b*) *Decrease.*—Overbreathing—voluntary, in hysteria, emotional, as a result of peripheral stimuli, in fevers, at high altitudes, in renal asthma.	(*a*) *Decrease.*—Excessive ingestion of acids, or potential acids (NH_4Cl or $CaCl_2$). Excessive formation of acids—lactic acid in exercise. Failure of oxidation of acids—especially acetoacetic acid. Failure of excretion of acids in nephritis. Loss of base. (*b*) *Increase.*—Excessive ingestion of bases ($NaHCO_3$) or potential bases (e.g., sodium citrate). Loss of acid.

In the same way in type 1 (*b*), when the atmospheric oxygen pressure is reduced at high altitudes, the excessive breathing required to take in sufficient oxygen reduces the H_2CO_3 in the blood below normal so that at 15,000 feet the pH may rise to 7·5 or 7·6. The kidneys can remove moderate amounts of acid or base as fast as they are formed or ingested; it is only when the amounts are excessive or the kidneys damaged that appreciable acidosis or alkalosis occurs. Thus a patient may pass considerable amounts of acetone bodies in the urine without any reduction of c($NaHCO_3$) or increase of cH, and large doses of aklalis such as grs. 300 of sodium bicarbonate may be taken daily without an increase in c($NaHCO_3$).

TABLE II.—*Examples of Disturbance of Acid-base Balance.*

Type.	—	pH.	cH.	Bicarbonate c.cm. of CO_2 per 100 c.cm.		Free H_2CO_3 c.cm. of CO_2 per 100 c.cm. plasma.	—
				Plasma.	Blood.		
—	Normal.	7·30 to 7·45	$\frac{1}{20,000,000}$ to $\frac{1}{28,000,000}$	55–65	46–54	2·5 to 4·0	—
1 (*a*)	CO_2 Breathing.	7·10	$\frac{1}{12,500,000}$	65	54	6·5	Primary increase of c(H_2CO_3).
1 (*b*)	Voluntary hyperpnœa.	7·60	$\frac{1}{40,000,000}$	50	43	1·6	Primary decrease of c(H_2CO_3). Some compensatory reduction of c($NaHCO_3$). Tetany.
	High altitude. Compensated.	7·40	$\frac{1}{25,000,000}$	40	34	2·0	Primary decrease of c(H_2CO_3). Compensatory reduction of c($NaHCO_3$) by excretion of base in urine.
2 (*a*)	Ketosis (starvation). Moderate acidosis. Compensated.	7·40	$\frac{1}{25,000,000}$	45	38	2·2	Primary reduction of c($NaHCO_3$) by retained acetone bodies. Compensatory reduction of c(H_2CO_3).
	Exertion. Medium acidosis. Uncompensated.	7·15	$\frac{1}{14,000,000}$	38	32	3·4	Primary reduction of c($NaHCO_3$) by lactic acid.
	Nephritis. Severe acidosis. Uncompensated.	7·10	$\frac{1}{12,500,000}$	15	13	1·5	Primary reduction of c($NaHCO_3$) by retained H_3PO_4 and H_2SO_4. Some compensatory reduction of c(H_2CO_3). No signs of uræmia. Blood-urea 0·32 per cent.
2 (*b*)	Dosage with $NaHCO_3$. Mild alkalosis. Compensated.	7·43	$\frac{1}{27,000,000}$	78	65	3·6	Primary increase of c($NaHCO_3$). Rather high c(H_2CO_3).
	Pyloric obstruction. Severe alkalosis. Uncompensated.	7·60	$\frac{1}{40,000,000}$	119	99	3·8	Primary increase of c($NaHCO_3$) owing to loss of HCl by vomiting. Collapse, cyanosis, feeble breathing, tetany.

Compensation.

In all these conditions attempts at compensation take place; in particular, in type 1 (*a*) alkali is excreted in the urine so that c($NaHCO_3$) is reduced, while in 2 (*a*) CO_2 is washed out by increased respiration and c(H_2CO_3) is reduced. Thus in both types both c(H_2CO_3) and c($NaHCO_3$) are reduced, and it may be difficult to decide which was the primary change. However, as a rule, the compensation is not complete—that is, the cH is not brought completely back to normal, so that measurement of cH settles the question; in many cases also the history excludes any doubt.

Effects of Disturbance.

Disturbances of the acid-base balance produce general effects only in so far as the cH of the body fluids is altered. Within limits increase of cH has little effect beyond causing hyperpnœa. The acidosis produced by NH_4Cl and $CaCl_2$ is followed by a profuse diuresis, and has been used for treating œdema in nephritis; also increase of cH appears to reduce the irritability of the neuromuscular junctions and NH_4Cl acidosis has been used for the treatment of tetany in children due to low plasma calcium. The bad effects of severe NH_4Cl acidosis found by J. B. S. Haldane in experiments on himself were probably due to an extremely severe local acidosis in the liver, where neutral NH_4Cl was converted into an acid mixture of urea and hydrochloric acid; such an intense local production of strong acid does not occur in any natural acidosis. It is significant that violent exercise normally produces an acidosis with great increase of cH, since owing to the increased production of CO_2 at the same time it is impossible to compensate for reduction of $NaHCO_3$. The acidæmia at the end of a quarter-mile race must exceed anything seen in pathological conditions except just before death. Neither uræmia, nor the symptoms of diabetic coma (other than hyperpnœa) are due to acidosis, per se, nor are they improved by alkalis. There is therefore no evidence that acidosis is the cause of any disease.

The conditions in types 1 (*b*) and 2 (*b*), in which the change is towards the alkaline side, are more serious. In the first place compensation presents difficulties; compensation for reduced c(H_2CO_3) is slow, so that accommodation to high altitudes takes some weeks, and compensation for increased

$c(NaHCO_3)$ involves reduced respiration with consequent reduction of oxygen intake.

When uncompensated, both these conditions lead to a reduction of cH, which is accompanied by interference with the oxygen supply to the tissues and various nervous manifestations. When the cH is reduced hæmoglobin gives up oxygen to the tissues less readily, so that the body may be starved of oxygen although the blood is well oxygenated; and with reduction of cH the neuro-muscular junctions are more irritable, so that tetany or even general convulsions may develop. A mild ketosis is frequently found in conditions in which the blood cH is decreased.

Chemical Pathologist to the London Hospital.

Special Articles.

ON THE VISCERAL LESIONS THAT MAY ACCOMPANY EXPERIMENTAL VACCINIA IN RABBITS.

BY J. C. G. LEDINGHAM, C.M.G., D.Sc. Aberd., F.R.C.P. Lond., F.R.S.,
CHIEF BACTERIOLOGIST TO THE LISTER INSTITUTE; PROFESSOR OF BACTERIOLOGY IN THE UNIVERSITY OF LONDON;
AND
MARY M. BARRATT, M.B. Edin.,
ASSISTANT BACTERIOLOGIST TO THE INSTITUTE.

IT is the purpose of this communication to place on record certain observations on a subject to which attention has been drawn by Douglas, Smith, and Price (1929) in a recent important paper.

That the virus of vaccinia is capable of invading the system from a skin area in which it has been inseminated and may be recovered from the blood and organs, though at times with considerable difficulty and by the aid of special methods, is now fully recognised. It was largely the work of Ohtawara (1921) based on the intratesticular method of virus-propagation devised by Noguchi (1915) that paved the way for demonstrating experimentally this capacity of virus to invade. The new knowledge accorded well with what we have long known of the symptomatology of localised vaccinia, both in man and animals, as a febrile disease accompanied, it may be, by at least one clinically demonstrable visceral disturbance —viz., acute splenomegaly. So long as the ordinary cutaneous strains of lymph continued to be used for the study of experimental vaccinia in rabbits, there was no good evidence that such virus, though capable of invading, had also the power to produce discrete naked-eye lesions in viscera after simple cutaneous insemination. The early work of Calmette and Guérin (1901) showed, indeed, that after intravenous introduction of such virus, vaccinial lesions were liable to appear on shaved areas of skin. In eliciting even this simple and striking phenomenon, however, subsequent observers have not been invariably successful and, doubtless, the reason for the failure has to be sought in the employment of inadequate doses of virus. It was, in fact, the comprehensive and minutely documented work of Camus (1917–18) which demonstrated clearly and for the first time that vaccine virus of cutaneous source was capable, when administered intravenously and in adequate dose, of producing characteristic vesicles and papules about the mouth, lips, nose, tongue, buccal cavity, eyelids, palpebral conjunctivæ, and genital orifices of experimental animals.

The work of Camus, comprehensive and detailed as it was, does not appear to have received the attention it undoubtedly merits as a fundamental contribution to this subject. Camus describes and figures the lesions of generalised vaccinia not only in rabbits, but also in guinea-pigs, dogs, cats, bovines, and monkeys. These lesions were invariably produced provided an adequate dose of a "purified" virus was inoculated into their veins. Adequacy of dose was of prime importance. While the generalised lesions in rabbit and guinea-pig were largely confined to the sites mentioned, and were only occasionally noted in the unshaved skin, in the dog and cat cutaneous lesions were the rule. It does not appear that Camus noted any visceral lesions, regarded by him as vaccinial, in those rabbits which died either owing to the intensity of the eruption itself or from secondary bacterial infections. It is, however, of very considerable interest in the light of more recent work that some of Camus's animals, which died later in a cachectic state, showed white spots in liver and spleen which Camus interpreted as evidence of secondary bacterial infection. He records, indeed, the cultivation of staphylococci from such spots. Congestion of the ovaries was noted by him, but he makes no mention of renal or pulmonary lesions.

The results of Camus's work, in so far as they concern the production of lesions in the neighbourhood of mucous orifices, have been fully confirmed (Uhlenhuth and Bieber, 1923; Watanabe, 1924, &c.).

Levaditi and Nicolau (1923) in their study of neurovaccine saw similar lesions to those described by Camus after intravenous injection of the virus. Their work was, in the main, directed to the recovery of virus from various organs with a view to securing evidence of affinity of virus to tissues of epiblastic origin, and in the course of this work they demonstrated the fairly constant presence of virus in adrenals, lung, &c. No naked-eye lesions in liver, lung, or adrenal were noted by them, but they describe and illustrate what they take to be microscopic inflammatory foci of vaccinial origin in lung, liver, and interstitial tissue of the ovary. Watanabe (1924), using glycerinated lymph and the intravenous method, demonstrated in rabbits the production of vaccine pustules about the face, as Camus had done, but his results are of special interest in that he noted the presence on the hairy skin of numerous small papules with hæmorrhagic centres. Histological examination of these papules revealed inflammatory reactions in the dermis only. Epithelium was not involved. These papules he believed to be caused by the virus. They did not appear when the virus was inoculated intravenously into immune rabbits. One of us (Ledingham, 1924) in the course of an investigation of the tissue affinity of vaccinia, inoculated the virus directly into the spleen. A specific lesion was produced locally, and a crop of secondary vaccine papules which were described and figured appeared on the serosa of adjacent coils of bowel. Similarly, when introduced into the peritoneum the virus gave rise to omental papules of like histological structure. It appeared, therefore, that vaccine virus of cutaneous origin had the capacity, if a somewhat feeble one, to produce lesions in abdominal viscera when directly introduced.

Our knowledge, however, of the generalising potentialities of the vaccine virus has been considerably increased by the experimental results recorded by Douglas, Smith, and Price (1929) working with potent doses of neurovaccine or neurotesticular vaccine introduced by various routes. In addition to lesions about the mouth, nose, and eyes corresponding to the picture of Camus, and which were frequently accompanied by acute catarrhal processes, they describe and illustrate multiple lesions in the hairy skin and macroscopic foci in lungs, liver, adrenals, testicles, ovaries, mammary glands, spleen, and intestinal serosa. Though elicited with greatest constancy and intensity by the intravenous route, these visceral lesions were liable on occasion to follow intracutaneous, intracerebral, and intraperitoneal inoculations of neurovaccine. Douglas and his colleagues give no histological details of these visceral lesions. They state, however, that bacteriological examinations of various tissue lesions and fluids gave consistently negative results and that, therefore, secondary bacterial infections might definitely be excluded from playing a part in the genesis of the lesions. McIntosh and Scarff (1929), who have encountered similar lesions by similar methods, also state that there was no evidence in their rabbits of the presence of secondary infections such as—e.g., pasteurella.

Some months before the paper by Douglas, Smith, and Price appeared, one of us (L.) who had had the advantage, through the kindness of Capt. Douglas of seeing these visceral lesions in the rabbit, and of studying the histology of casual specimens, commenced experiments with neurotesticular vaccine in order to secure some personal experience with this potent type of strain. It was soon noted that certain animals after intravenous inoculation developed acute catarrhal eye conditions, while other animals inoculated intradermally with the same virus presented characteristic lesions on adjacent areas of shaved skin. At later stages these animals also were liable to develop acute catarrh about the eye and nose. If such animals died or were sacrificed the remarkable picture described by Douglas, Smith, and Price was generally in evidence either in full or modified form. A very notable feature of this picture was the massive involvement of the uterine horns in pregnant females which at one time led to abortion and at another to death in loco of the fœtuses. The latter picture was especially noted at autopsies performed some two to three weeks after intracutaneous titration of neurotesticular vaccine on the shaved backs.

The successful cultivation of *P. lepiseptica* from the eye discharge in some of these cases, and from similar discharges in uninoculated stock rabbits during the winter months led one of us (L.) to put forward the suggestion, in the course of recent discussions on viruses, that in the genesis of these remarkable lesions latent bacterial infections stimulated to activity by the introduction of a potent vaccine virus, might play a part, and that the vaccine virus might not be solely responsible. Histological examination of visceral lesions and of tissues kindly lent by Capt. Douglas had revealed the presence of massive cell necroses (chromatin comminution) with little or no evidence of repair, and it became, therefore, a question how far it was possible to distinguish casual lesions of this character from those due—for example, to pasteurella organisms which are known to produce necrotic lesions in lungs and liver. Moreover, the not infrequent occurrence in uninoculated rabbits or rabbits inoculated with materials other than vaccinia, of casual discrete pearly spots in lungs and livers, required careful consideration in correctly appraising the visceral lesions following inoculation with neurovaccine. Such spots are often bacteriologically sterile, but they may, nevertheless, represent healed or healing granulomatous lesions due primarily to bacteria. Histological examination has shown that slight coccidial liver infections may, on occasion, take the form of quite small pearly foci liable to be confused with the miliary pearls described in the liver following the introduction of neurovaccine. These difficulties are illustrated below in discussing the histological features of the visceral lesions, and the point emerges clearly that the examination of successive stages in the evolution of the lesions can alone give confidence in interpretation.

The suggestion that organisms of the pasteurella group might possibly play a part was also strengthened by the experimental data of Pette (1928) who, in the course of an attempt to repeat the work of Luksch, had the unusual experience of seeing rabbits, scarified or otherwise inoculated with lymph, die of acute pasteurellar infection. Examination of the nasal mucosæ of clinically healthy stock rabbits revealed pasteurellar infection in 10 per cent. of the animals.

Record of Authors' Experiments.

We propose here to place on record a brief series of experiments designed to determine whether such suggestion as to the origin of the visceral lesions was valid, and if so, to what extent; and, secondly, to give some details of the histology of these visceral lesions which are new to pathology. It may be said at once that the above-cited suggestion, based on the initial experiences, has received only a modified support from further work, and that the capacity of vaccine virus under appropriate conditions to produce widespread visceral lesions in rabbits must be frankly admitted.

The present bacteriological and histological study is based on two main sources of material:—

Source A.—Eight rabbits were inoculated intradermally in numerous spots over the shaved back in the course of titration of neurovaccine or of similar virus grown in contact with living cells. For this material we are indebted to Drs. Eagles and McClean. The following brief particulars are appended with regard to these eight animals:—

R.65: Conjunctivitis noted fifteenth day. Killed sixteenth day. Scattered foci in liver. *R.69*: Intradermal reactions feeble, but generalisation on skin noted seventh day, and conjunctivitis on twentieth day. Killed twenty-first day. Lesions in liver, lungs, and uterine horns. *R.70*: Intradermal reactions feeble. Conjunctivitis noted tenth day. Killed twenty-first day. Foci in ovary, uterus, liver, and lungs. *R.76*: Intradermal reactions feeble. No conjunctivitis. Dead on twentieth day. Pregnant, multiple lesions in uterus, ovary, kidney, and liver. *R.81*: Intradermal reactions strong. Skin generalisation. Dead on twenty-fifth day. Pregnant, massive necrotic lesions in uterus and multiple foci in lungs. *R.85*: Intradermal reactions strong. Emaciation ensued. Killed sixth day. Not pregnant. Numerous foci in spleen, liver, lungs, and adrenals, and a few in uterine horns. *R.73*: Intradermal reactions feeble. No generalisation. No conjunctivitis. Died after 60 days. Some white spots on liver and uterus *R.93*: Intradermal reactions normal. On this occasion pure dermal virus used. Killed on fourth day to secure passage material. Liver showed many pearly foci.

Source B.—Sixteen animals were inoculated intravenously or intradermally and intravenously with neurotesticular vaccine. Of these 16 animals 12 belonged to one series, all of which received the same dose of neurovaccine intravenously on the same day—viz., 2 c.cm. of a 1 in 10 dilution of a strain of neurovaccine which was capable of producing dermal reactions in a dilution of 1 in 1,000,000.

The weights (in oz.) and temperatures of these 12 animals before and after inoculation on July 2nd are shown in the Table. (+ = death).

It will be noted that eight animals died between the sixth and twelfth day. Apart from the picture described by Camus (pocks about the lips, nose, and eyelids) particularly intense lesions appeared on the ear employed for intravenous injection. The ear either showed a diffuse board-like thickening or more commonly the substance of the ear was beset with hard shotty papules. In one case only were shotty nodes observed in the opposite ear. At the autopsies of the fatal cases the picture was substantially that described by Douglas, Smith, and Price, but varied slightly in intensity in individual cases. Five of the animals had pocks about the mouth, tongue, nose, and eyes, but in two only was there an acute purulent discharge with keratitis. Slight mucoid discharges at the canthi were usually associated with the presence of a pock on the eyelid. In four of the fatal cases the skin of the back and the underlying fasciæ were beset with purpuric spots often confluent, the picture recalling strongly that met with in the skin of rabbits inoculated with an antiplatelet serum. The purpura was associated with considerable œdema of the dermal tissues, and the lymph glands of axilla and groin were of the red hæmolymph type. In these essentially hæmorrhagic cases lungs and other organs were beset with petechiæ. The bladder usually contained blood-stained urine, and in one case a large fresh blood-clot almost filled the vesical cavity. It should be noted also that the purpuric areas in the skin of the back contained no formed papules, death having taken place too early for these to develop.

Bacteriological Investigations.

During the months November, 1928, to April, 1929, when acute catarrh of eye and nose was liable to intervene at some period following intradermal or intravenous inoculation with neurotesticular vaccine bacteriological examination of these catarrhal discharges and of organs in which lesions were detected when the animal was sacrificed or succumbed were carried out by one of us (B.). It is unnecessary here to record the findings in detail, as in a few cases only were results of definite significance obtained. From the eye discharges of three of the earlier cases of the winter series, organisms corresponding in cultural and biochemical characters with *P. lepiseptica* were recovered, while from five cases pasteurella-like organisms more closely resembling *Bacillus bronchisepticus* were obtained. From the nasal discharges of four cases *P. lepiseptica* was recovered in one case and from another a pasteurella-like organism. Representatives of this group were naturally searched for with special care in view of their association with snuffles in rabbits and their possible "activation" from latency by the inoculation of a potent virus. No evidence, however, was obtained of the presence of organisms of this group in organs showing lesions. When such organisms were present in an eye discharge but absent from an organ lesion it was not possible to exclude definitely participation of pasteurella if the lesion happened to be of some standing, as it is known that these organisms may be only with difficulty, if at all, recoverable from lesions in process of repair.

As we shall see later, the pearly lesions found in the livers of intradermally inoculated animals after a period of three weeks were usually of the granulomatous type. In no case was a blood invasion by *P. lepiseptica* demonstrated. On the other hand, in two cases in which cultivations were made from the intensely hæmorrhagic and œdematous dermal tissue characteristic of the dermal response to neurotesticular vaccine, and from adjacent generalised skin papules, an organism not yet identified, but culturally resembling *P. lepiseptica* was recovered in pure culture. While, therefore, in intradermally inoculated animals sacrificed about the third week no clear evidence of participation of bacterial infections in the visceral lesions was forthcoming, it was definitely established that secondary bacterial infections were a contributory cause of death when such animals succumbed as occasionally happened. In *R. 81* (see Source A) for example, which was found dead on the twenty-fifth day, all the organs examined contained pneumococci in pure culture, and sections revealed a massive invasion by these organisms. Doubtless the pregnant state coupled with the necroses of the uterine wall due to virus action predisposed to secondary bacterial invasion. In another instance evidence of bacterial invasion was obtained in a rabbit which was killed for histological study on the seventh day after intravenous inoculation of neurovaccine. Spleen films made immediately after sacrificing the animal revealed the presence of a Gram-positive rod, and a culture of an anthracoid organism was obtained, not only from the spleen but from uterus, liver, and lung. The colonies obtained were few in each case, and in all probability the organism was in process of dying out after a brief blood invasion. The circumstance is noted, however, as it recalled a former case in the experience of one of us in which a rabbit inoculated with calf lymph intradermally was found dead on the fourth day. From all its organs *B. anthracis* was recovered. No work on anthrax was in progress at the time.
